THE
GARDENERS' CHRONICLE

A Weekly Illustrated Journal

OF

HORTICULTURE AND ALLIED SUBJECTS.

(ESTABLISHED IN 1841.)

VOL. XLIX.—THIRD SERIES.

JANUARY TO JUNE, 1911.

LONDON:

41, WELLINGTON STREET, COVENT GARDEN, W.C.

1911.

INDEX OF CONTENTS.

JANUARY TO JUNE, 1911.

(FOR SPECIAL HEADINGS SEE UNDER BOOKS; CERTIFICATES; LAW NOTES; NURSERY NOTES; OBITUARY; PLANT PORTRAITS; PLANTS, NEW; SCIENTIFIC COMMITTEE; SOCIETIES, AND ILLUSTRATIONS.)

A

ABERDEEN College of Agriculture, 261
 Aberdeen Cruickshank Botanic Gardens, 367
 Aberdeen Sweet Pea Show, proposed, 188, 293
 Abutilon *Thompsonii* and *A. Thompsonii* *spurius*, 29; *A. Thompsonii* *flora plena*, 29, 170
 Acanthopanax *ricinifolium*, 213
 Acer *pennsylvanicum*, 235
 Acorn producing two plants, 400
 Adiantum *Farleyense* raised from spores, 72
 Adiantum *Gloria of Moordrecht*, 77, 172
 Agricultural Congress at Madrid, 281
 Agricultural education, 153; in Canada and the United States, 81
 Agriculture, Aberdeen College of, 261; International Institute of, 41; in the West Indies, 78, 82, 101; Tobacco for use in, 382
 Alderman, Mr. A., presentation to, 281
 Allan, Mr. John P., retirement of, 75
 Allotment gardens, improving the soil of, 12
 Allotments, 203
 Almond, date of flowering of the, 170
 Alpine garden, the, 65, 100, 117, 164, 189, 195, 211, 250, 261, 343, 414
 Alpine plants, a frame for wintering, 212; new work on European, 90
 Alps, European, *Primulas* of the, 344, 364, 385, 413
 American blight on Apple trees, 192
 American Gooseberry-mildew, 13, 58, 156; outbreak of summer stage of, 298
 American Hawthorn, 17; new arborescent species of, 36
 Amelanchier, the genus, 340
 Ampelopsis *Vitifolia* in America, 131
 Anemones, St. Bridget, at Blackpill Nurseries, Swansea, 328
 Augreum *pellucidum*, 18
 Anthracite coal and coke for heating greenhouses, 64
 Ants, to destroy, 288
 Aphides and ladybirds, 169
 Apiary, the, 23, 71, 119, 135, 183, 215, 246, 263, 311, 349, 369, 399, 409, 425
 Apios *tuberosa*, 4, 25, 91
 Apple Cox's Orange Pippin, 309; Miller's Seedling, 85; Newtown Pippin as a late variety, 157; Samson, 16
 Apple cultures for profit, 158; in Devonshire, 76; in Dorsetshire, 53, 51
 Apple trees, American blight on, 192; in hedges, 271; the use of ties in training, 146
 Apples, shipments of Australian, 138; British *var.* Foreign, 45, 58, 76, 92, 123; for market, 105; late dessert, 139; late keeping varieties of, 4, 157, 190; on stiff soils, 85
 Appointments abroad, 90; at Kew, 169; to London public parks, 330
 Aquilegia *flabellata*, 199
 Aquilegias, the culture of, 266
 Arbor day at Grantown, 261
 Arboriculture in Germany, 114
 Arkway, a floral, erected at J. Jamesburg, 155

Arley, specimen trees at, 11
 Armeria *caespitosa*, 211
 Armillaria *melles* attacking Willows, 100
 Arnold Arboretum, the, 391
 Arundinaria *fastuosa* at Gummerbury House Gardens, 252
 Ashton Court, Bournemouth, Rhododendrons at, 392
 Asimina *triloba*, 252
 Asparagus bed, to prepare an, 400
 Asparagus *Hatcheri*, 170
 Atmospheric impurities and vegetation, 426
 Aubrietia, Mrs. E. M. Crosfield, 261
 Auricula, the, 164
 Australia, *Pinus insignis* in South, 314; the Pines of, 243
 Australian Apple season, the, 158
 Avery Hill, L.C.C. nursery, extension of, 250

B

BACTERIALS *solanacearum*, a disease of Potatoes, 186
 Bacterial disease of Potato, a, 186
 Bazetelle, a trial of Roses at, 169
 Bayley, Mr. F. Manson, honour for, 9
 Baker, R. T., and H. G. Smith, *A Research on the Pines of Australia*, 243
 Ballantine, Mr. Henry, retirement of, 202
 Bamboos at Kew, 115; for a Leicestershire garden, 123; in tubs, 307
 Banana culture in England, 13, 23
 Band contest in Glasgow public parks, 293
 Banks, Sir J. seph, 201
 Barassie, garden city at, 42
 Bardswell, Frances A., *The Herb Garden*, 374
 Barnard, Mr. H. A., 298
 Baron Hill, Beaumaris, 122
 "Barr" Memorial Fund, 170
 Bartlett, Mr. A. C., appointment of, 217
 Basic slag, effect of, on pastures, 91
 Bateson, Professor W., to deliver the "Herbert Spencer" lecture, 350
 Beach, transplanting a large, 133
 Bee stings, a remedy for, 315
 Bees, the epidemic amongst, 265; the management of, 23, 71, 119, 135, 183, 215, 246, 263, 311, 349, 369, 389, 409, 425
 Begonia *Gloria de Sceaux* at Bryanston Gardens, Blandford, 372
 Begonias, winter flowering, 202
 Belgian horticultural society, the oldest, 218
 Belladonna plaster a remedy for bee-stings, 313
 Belvedere, Isle of Wight, rare plants at, 10
 Belvoir Castle, Grantham, spring-bedding at, 184, 264
 Benary, Ernest, *Die Erziehung der Pflanzen aus Samen*, 308
 Benevolent Institution, Gardeners' Royal, 25, 29, 41, 56, 153, 313, 427; (annual election), 46; (annual meeting), 60; (festival dinner), 339
 Bequests to gardeners, 28, 281, 307
 Berberis *Silver Beauty*, 10
 Berlin Rose show, 217
 Biochemists at Rothamsted, 410
 Biology, economic, and museums, 170

Bird sanctuary, the Brent Valley, lecture on, 254
 Birds, and fruit buds, 229, 304; and fruit-nets, 394; the coming of the warbler, 323; the protection of, 137
 Birmingham, flower shows at, 298
 Black Currant, big-bud in, 64; Boskoop Giant and big bud, 91; buds and bullfinches, 171, 190
 Black Currants as a market crop, 132
 Blackman, Prof. V. H., appointment of, 121
 Blairgowrie fruit-carriage dispute, 210
 Blue-berry, taming the wild, 367
 Boiler, which is the best? 380, 400
 Bomarea *patatocensis*, 372; fruits of, 227
 Bongardia *Rauwolfii*, 235

BOOKS, NOTICES OF:— **A** Course of Practical Work in Agricultural Chemistry for Senior Students (*T. E. Wood*), 116; **A** Flora of Western Middle California (*Willis Linn Jepson*), 179; **A** Monograph of the British Lichens (*A. L. Smith*), 371; **A** Research on the Pines of Australia (*R. T. Baker and H. G. Smith*), 243; **B**otanical Magazine, 89, 155, 217, 313; **B**ritish Fern Gazette (*Charles T. Drury*), 217; **B**ritish Ferns and their Varieties (*Charles T. Drury*), 131; **C**arnations and Pinks (*T. H. Cook, J. Douglas, and J. P. McLeod*), 238; **C**hloris *Platanis Argentina* (*Cristobal M. Hicken*), 308; **C**ontributions from the United National Herbarium (*Henry Patton*), 344; **C**rown Gall of Plants: Its Causes and Remedy (*Erwin F. Smith*), 312; **C**oming of Evolution (*John W. Judd*), 49; **E**ie Erziehung der Pflanzen aus Samen (*Ernst Benary*), 308; **E**nglishwoman's Year Book and Directory (*G. E. Mitton*), 41; **F**lora of Buenos Aires (*Cristobal M. Hicken*), 308; **F**lora of Jamaica (*William Fawcett*), 82; **G**arden Foes (*T. W. Sanders*), 115; **G**ardening Year Book (*G. Gordon*), 41; **G**uide to Mr. Worthington G. Smith's Drawings of Field and Cultivated Mushrooms and Poisonous or Worthless Fungi often Mistaken for Mushrooms (*Worthington G. Smith*), 116; **I**rish Farming World Directory and Annual, 41; **J**ournal of the New York Botanical Gardens, 329; **K**ew Guild Journal (*Herbert Cowley*), 121; **L**ive Stock Journal Almanac, 41; **M**y Garden Diary for 1911 (*Sutton & Sons*), 41; **O**rchid Review, 91; **O**rchids (*James O'Brien*), 4; **O**rchids for Everyone (*C. H. Curtis*), 164; **O**rchid World, 232; **P**lant Animals: a Study in Symbiosis (*Professor Frederick Kobb*), 277; **P**ears' Cyclopaedia (*James Burdley*), 41; **P**hytopathological Society's Journal, 260; **P**opular Greenhouse Flowers (*Walther P. Wright*), 373; **P**ractical Plant Physiology (*Frederick Kobb*), 384; **P**rofitable Bee-keeping (*H. Georg*), 293; **P**ublications received, 9, 26, 41, 74, 91, 106, 170, 186, 202, 253, 265, 281, 298, 351, 371, 391; **R**ecords of the Botanical Survey of India (*Majur*

J. P. Gage), 325; **R**eport of a deputation appointed by the Council of University College, Reading, to visit selected centres of agricultural education and research in Canada and in the United States, 81; **S**chlich's Manual of Forestry (*Sir W. Schlich*), 216; **S**imple Lessons in Nature Teaching (*John O'Neill*), 131; **S**weet Pea Annual, 1911 (*Chas. H. Curtis and Horace J. Gage*), 325; **V**inton's Agricultural Almanac and Diary, 41; **W**ebster's Foresters' Diary and Pocket Book (*A. D. Webster*), 41; **W**ho's Who, 1911, 41; **W**illing's Press Guide, 41; **W**riters' and Artists' Year Book, 41
 Boskoop Jubilee flower show, 90, 121, 186, 239
 Boston, U.S.A., flower show, 297
 Botanical expedition to Lower Siam, a, 361, 385, 406
 Botanic garden, a national, for South Africa, 8
 Botanists, British, lectures on, 88, 113, 152, 232, 328
 Botany, the rise of systematic, in England, 113
 Botrytis *cinerea* on greenhouse plants, 154
 Bonnyville, cottage gardens at, 281
 Bowling greens, Edinburgh public, 132
 Boyd, Mr. William, presentation to, 281
 Brasso-Cattleya *Senateur de Bast*, 137; *B. C. Vilhormiana*, 98, 146, 180
 Bread, whole meal, 74
 Brent Valley Bird Sanctuary, the, lecture on, 254
 Britain as a market for French fruit, 24
 British botanists, 88, 113, 152, 232, 328
 British forestry, the development of, 170, 220, 253, 985
 British horticulturists in America, 219
 Broom, early flowering of the, 253
 Brown, Mr. John, presentation to, 58
 Brown rot on Plums, 324
 Brussels Sprouts, the culture of, 156
 Brussels State Botanical Gardens, 366
 Bryanston Gardens, Blandford, *Begonia de Sceaux* at, 372
 Buddleia *officinalis*, 201

Bulb garden, the, 98, 211, 189, 347, 386
 Bulb industry of the Netherlands, 9
Bulbophyllum cylindraceum, 5; *B. tremulum*, 291
 Bulb show, a children's, 183; R.H.S., 173
 Bulbs, manures for, 176
 Bulfinches and Black Currant buds, 171, 190
 Burbage nurseries, experimental station at the, 233
 Button hole holder, a new, 360

C

CABBAGES, a trial of, 423
Calanthe Veitchii, 50
Calanthes, at Cavenham Park gardens, Mildenhall, 83; the culture of, 163
 Calcutta Botanic Gardens, trees and shrubs in, 323
 Calthrop, Dion Clayton, *The Charm of Gardens*, 147
 Cambridgeshire, American Gooseberry-mildew in, 24; spraying demonstrations in, 350
 Camellias, the culture of, 80
 Canadian nursery, a, 177
Canarina Campanula, 249, 266
 Canker, Rose, 295, 343
 Carbon bisulphide as a ground insecticide, experiments with, 351
 Cardiff, gift of a public park to, 315
 Cardiff public parks, 234, 244, 334
 Carnations, forcing, to flower in May, 360; novelties in, 26, 393; perpetual-flowering, 13
 Carrot-fly, the, to combat, 304
 Castlewellan, Co. Down, early-flowering *Rhododendrons* at, 157
Catasetum Rodigasianum, 291
Cattleya Warscewiczii alba, 412
Cattleyas, hybrid, 323
 Cavenham Park gardens, *Calanthes* at, 83
 Census, gardeners and the, 201; of vegetation, 391.

CERTIFICATED FRUITS AND VEGETABLES:—*Asparagus* Early French, 301; *A. Green Canadian*, 301; *Cabbage Harbinger*, 301; *Cucumber Pride of the Market*, 430; *C. Improved Telegraph*, 430; *Kale Labrador*, 301; *The Newberry*, 431

CERTIFICATED PLANTS:—*A dianium* *Glory of Moordrecht*, 77, 172; *Anthurium Scherzerianum maculatum*, 319; *Asplenium decorum*, 300; *Aubrietia* Mrs. Lloyd Edwards, 319; *Auricula* *Emmie*, 318; *A. Juliet*, 318; *A. Kingswood*, 318; *A. Mrs. Gardiner*, 236; *A. Mrs. Harry Veitch*, 236; *A. Mrs. Simonite*, 318; *A. Miss Mary Chamberlain*, 318; *A. Raven's Plum*, 318; *A. Richard Holding*, 318; *A. Sulphur Queen*, 319; *A. Umpire*, 268; *Azalea amena* var., 191; *Begonia* *Lady Cromer*, 431; *B. Mrs. Peter Blair*, 431; *Brasso* *Cattleya* *Queen Alexandra* *superba*, 191; *B.-C. Senateur de Bast*, 108; *B.-C. Euterpe*, 78; *Bulbophyllum galbinum*, 46; *Carnation* *Charlotte Bronte*, 430; *C. Coronation*, 107; *C. Edith Waters*, 287; *C. Empire Day*, 205; *C. F. W. Goodfellow*, 430; *C. Snowstorm*, 319; *Cattleya Mendellii* *Dainty*, 255; *C. Mossiae aureola*, 376; *C. M. var. G. M. Males*, 333; *Cologyne burfordensis*, 333; *Colax Charlesworthii*, 255; *Crinum Johnstonii*, 376; *Cyclamen* (*Papilio* strain), 14; *Cymbidium* *Alexanderi*, 174; *C. Gottianum*, 174; *C. Langleyense*, 142; *C. Pauwelsii*, 108; *Cypripedium aureum laekenense*,

108; *C. Bridgeri*, 191; *C. Carola*, 108; *C. Charles Sladdin*, 46; *C. Duke of Connaught*, 78; *C. Lawrenceanum* *Hyeannum* *G. S. Ball's* variety, 255; *C. niveum* *Oakdene* variety, 255; *C. Vogelzang*, 46; *Davidia involucreta*, 338; *Delphinium* *Manve Queen*, 430; *D. Primrose Queen*, 430; *Dendrobium delicatum*, 142; *D. plumptonenae*, 191; *Dia-Cattleya Sanderi*, 269; *Eria lanata*, 142; *Grevillea robusta* *compacta*, 376; *Grobya fascifera*, 142; *Haberlea Ferdinandii* *Coburgii*, 338; *Heuchera sanguinea* "Nancy Perry," 376; *Hippeastrum* *Queen Mary*, 172; *Hydrangea hortensis* *Mme. E. Moullière*, 205; *Iris* *variegata* "Miss Eardley," 376; *Ismene festalis*, 300; *Laelio-Cattleya* *Canhamiana*, 319; *L.-C. Cranstone* *Westonbirt* variety, 14; *L.-C. Dominiana* *Monkend* variety, 174; *L. C. Germania*, 333; *L. C. Morningtonia*, 333; *Lewisia* *Cotyledon*, 339; *Lilium* *Martagon* *Hon. Mrs. Petre*, 431; *L. tenuifolium* *Golden Gleam*, 338; *Lycaste* *Mary Gratrix*, 191; *Miltoma* *Blonana* *Pectersiae*, 237; *M. Hyeana*, 301; *Myosotis alpestris* *Marie Raphael*, 319; *Narcissus* *Ajax* *Money-maker*, 378; *N. Crocus*, 237; *N. Elegy*, 287; *N. incomparabilis* *plenus*, *Queen of Phoenix*, 378; *N. Jacob Maris*, 378; *N. King George V.*, 378; *N. Matthew Arnold*, 287; *N. Middleton Favourite*, 287; *N. Miss Willmott*, 268, 287; *N. Mrs. Cato* *Boog*, 378; *N. Mrs. Lizzie Krelage*, 378; *N. Ormoh*, 287; *N. poetaz* *Aspasia*, 191; *N. Queen of Hearts*, 268; *N. Richard Strauss*, 378; *N. Seicle*, 378; *N. Sheba*, 287; *N. Socrates*, 268, 287; *N. Sonata*, 500; *Nephrolepis* *Batchelorii*, 255; *N. Marshallii* *compacta*, 236; *Odontioda* *Bradshawie* *Gatton* *Park* variety, 333; *O. Cooksoniae*, 14; *O. Coronation*, 333; *O. ignea*, 206; *O. Keighleyensis* var. *gloriosa*, 191; *O. Lambaiana*, 333; *O. rosefieldensis*, 237, 301; *O. r. Crawshayanum*, 430; *O. Vuystekeae* var. *Lady Colman*, 206; *Odontoglossum* *amabile* *Empress of India*, 333; *O. Black Prince* *Dell* variety, 333; *O. crispum* *Peacock*, 78; *O. Europa*, 430; *O. eximium* var. *Lady Wilkinson*, 191; *O. Godmani*, 46; *O. Halseyanum*, 46; *O. harvengtense* *Crawshayanum*, 301; *O. Harwoodii*, 78; *O. illustrissimum* var. *Queen Mary*, 301; *O. Jasper*, 255; *O. Jeanette*, 174; *O. Mansella*, 191; *O. Maria*, 78; *O. mirum* *Brugense*, 174; *O. Ossulstonii*, 237; *O. Phoebe* *Glenburn* variety, 191; *O. ramos-Edwardii*, 269; *O. rosefieldense*, 46; *O. Swietenicolor*, 206; *Odontodia* *Lairesii*, 255; *Oncidioda* *Cybele*, 376; *Oncidium* *Claesii*, 333; *O. Mulleri*, 333; *Oncoba* *Routledgei*, 236; *Pelargonium* *Maxim* *Kovalesky*, 236; *Philadelphus* *hybridus* *Lemoinei* *virginal*, 430; *Platyclinus* *glumacea* *valida*, 142; *Plocoglotis* *javanica*, 46; *Polyanthus* *Springfield* *Perfection*, 318; *Primula* *Auricula* *plena*, 255; *P. Chenies* *Excelsior*, 268; *P. pulverulenta* *Hidecote* strain, 376; *P. Winteri*, 141; *Rhododendron* *Corona*, 338; *R. Dawn's Delight*, 300; *R. Glory of Littleworth*, 339; *R. Littleworth* *Coralina*, 339; *R. Loder's* *White*, 338; *R. Mrs. Kingsmill*, 205; *R. Penger*, 268; *R. sinense* *Duchess of Portland*, 338; *R. (Azalea)* *sublanceolatum*, 338; *Rose* *Mar-*

cella, 236; *R. Mrs. Geo. Shawyer*, 300; *R. Orleans* *Rose*, 300; *R. Portia*, 339; *R. Sylvia*, 339; *Saxi* *fraga* *Bursiculata*, 141; *S. Petra* *s.iii*, 172; *Sophro-Cattleya* *Wellesleyae*, 191; *Sweet Pea* *R. F. Felton*, 430; *Trollius* *Derby* *Day*, 319; *T. Elsie* *Harkness*, 319; *Tulip* *Yellow* *Murillo*, 173; *Viola* *Moseley* *Perfection*, 300; *Xylobrium* *leontoglossa*, 108

D

Ceylon Botanic Garden, research work at the, 350
 Challis, Mr. Thomas, 50 years service, 26
 Charlcombe Grange, Grapes at, 313
 Charlock, the destruction of, 329, 394; by spraying with sulphate of iron, 400
 Chaucer and Gower, the flowers of, 401
 Chelsea Hospital, 154
 Cherry, insect pests of the, 256; the double flowered, 306
 Chicory, the forcing of, 212
 Chilton, Charles, *The Subantarctic Islands of New Zealand*, 209, 226
 Chinese trees and shrubs, seeds of, presented to Kew Gardens, 371
Chrysanthemum *Madame R. Oberthur*, 152
Chrysanthemums, incurved, 44; some of the best market varieties of, 26; some of the newer varieties of, 147
Cineraria *Beauty of Cambridge*, 307
Cinerarias, the culture of, 10
Citrus decumana, 208
Cladanthus *campanulatus*, 188
Clematis roots, nodules on, 360, 374
Clinanthus *panicus* at East Oakley House, Hampshire, 390
 Climbers suitable for a north-west wall, 16
Clintonia borealis, 98
 Clivia, a seedling, 163
 Clover, romance of a, 159
 Collin moth, the, in South Africa, 314
Colebicum hydrophilum, 98
 Cold storage of *Lilium* bulbs, 160
 Cole, Mr. Silas, appointment of, 217
Collabium nebulosum, 97
Columella on graft hybrid, 203
 Conifers of Australia, 243
Coniothyrium *Fackelii*, a disease of *Roses*, 293, 343
 Cook, T. H., *Carnations and Pinks*, 228
 Cornwall, the weather in, 252
Coronation bouquet, *Queen Mary's*, 152, 298, 427
Coronation, memorial tree for the, 266, 293, 316, 354
Coronilla glauca and *Veronicas* in Ireland, 156
 Cottage gardens, the value of, 281
 Crabs, ornamental, 13
Crassulus, the culture of, 80
Crataegus, new American species of, 17, 36
 Creosoted timber in greenhouses, 266, 420
 Cricket match, a gardeners', 351
 Cross-fertilisation, natural, 217
 Crown-gall disease of plants, 312
 Crown or Mummy Pea, the, 272
 Croys, Kirkcudbrightshire, fire in the garden at, 261
 Cruickshank Botanic Garden, Aberdeen, 367
 Cruickshank, the late Miss Annie H., 261
 Crystal Palace, the future of the, 190
 Cucumbers, the culture of, for market, 132
 Cultural memoranda, 10, 52, 165, 181, 387
 Curtis, C. H., *Orchids for Everyone*, 164
 Cyananthus, garden species of, 42
 Cycler industry, the, 305, 354
Cymbidium *Gottianum*, 180; *C. insignis* (syn. *Sanderi*), 194; *C. langleyense* (*Veitchii*), 146
Cypripedium *Charles Sladdin*, 50; *C. Duke of Connaught*, 83; *C. Miss Alice Wallace*, 50; *C. Vogelzang*, 308
Cypripediums as winter flowers, 18

E

EARTHWORMS in pots, 112
 East Burnham Park, visit of R.H.S. Committees to, 371
 Edgworthia chrysantha, 170
 Edinburgh, autumn show at, 307; golf course at Braid Hills, 210; public parks at, 132, 293; spring flower show at, 132, 245
 Edinburgh Town Council and the Scottish Horticultural Association, 58

Plant notes, 187, 196, 343
Plant novelties, awards to, 58
Plant physiology, 384; and pathology, appointment of Professor Blackman to chair of, 121
- PLANT PORTRAITS:**— *Cirrhopetalum longissimum*, 153; *Clematis aristata* var. *Dennise*, 217; *C. montana* var. *Wilsoni*, 153; *Deinantha caerulea*, 313; *Dendrobium muricatum* var. *munificum*, 217; *Elaeagnus argentea*, 217; *Felicia petiolata*, 217; *Kennedyia Beckxiana*, 89; *Lonicera Henryi*, 313; *Massevadalia pachyura*, 89; *Mecopopsis simplicifolia*, 153; *Meliosma cuneifolia*, 89; *Oncidium Sanderae*, 313; *Primula Maximowiczii*, 153; *Prunus microcarpa*, 89; *Pseuderanthemum malaccense*, 217; *Rhododendron lacteum*, 313; *R. sutchuenense*, 153; *Ureochloa edentata*, 89; *Villaresia mucronata*, 313
Plants, diploma for diligent interest in, 90; dispatching, to South Africa, 366; for summer bedding, 144; large Orchid, 123
PLANTS, NEW OR NOTEWORTHY: *Beaumontia fragrans*, 306; *Cypripedium luteum* and *C. tibeticum*, 492; *Fokienia Hodginsii*, 66, 84, 138, 253; *Iris chrysographes*, 362; *Oncoba Rattledgei*, 322
Plants, the protection of native, 170
Plants under glass, 7, 22, 38, 54, 70, 87, 103, 119, 134, 151, 166, 182, 199, 215, 230, 247, 262, 279, 294, 311, 327, 349, 368, 388, 408, 425
Pinguicula Rosei, 82
Pinguicula, Mexican, 292
Planting fruit trees, 146
Pleiocarpa nutica in Glasgow Botanic Gardens, 242
Plumbago rosea, 188
Plum, the Japanese Date, *Diospyros Kaki*, 40
Plum trees, an uncommon disease of, 374; aphid attack of, 309; brown rot on, 324; killed by *Eutypella prunastri*, 329
Podalyria calyptata in New South Wales, 242
Poisoning by Ivy, 139, 157, 170, 190
Poisonous shrubs, 13
Polytechnic, the Regent Street, 91
Ponds, scum on, 340
Poppies, Iceland, as cut blooms for market, 228
Potassium sulphide or liver of sulphur, 41

Potato blight, 248, 316; recent investigations on, 248; resting spores of, 374
 Potato scab, treatment for, 91
 Potatoes, a bacterial disease of, 186; disease-resisting, 181; high prices for, 250; importation of, into Jersey, 218; "seed," 152; varieties affected by scab, 186; wart disease of, 120, 122, 138
 Poultry industry, the, 153
 Poultry manure, the value of, 160
 Powerscourt, Co. Wicklow, 218
 Primula obconica and cats, 112; P. Reidii, 195; P. sinensis varieties, 153; P. vittata, 283; P. Winteri, 150
 Primulas of the European Alps, 344, 364, 385, 413
 Propagating, Genistas, 80; Heather, 80; Pinks, 394; plants from leaves, 266, 293, 400; vines from "eyes," 32
 Pruning of Roses, the, 129, 161, 193
 Prunus serrulata var. James H. Veitch, 306
 Pseudotsuga Douglasii, coast and mountain forms of, 307
 Pyrethrum Queen Mary as a market variety, 391
 Pyrus Tschonoskii, 213

Q

QUEEN Mary's Coronation bouquet, 169, 298, 427; basket of Roses, 423

R

RAINFALL, how to measure the, 372; in 1910, 25, 44, 59
 Ranunculus, the garden-, 138
 Ray, John, and systematic botany, 113, 136
 Red spider attacking vines, 284, 394
 Rhododendron barbatum at Castlewellan, Co. Down, 157; R. campylocarpum, 321; R. Cynthia, 406; R. Edgeworthii, 306; R. irroratum, 359; R. "Pengaer," 427; R. sublancolatum, 342
 Rhododendron at Ashton Court, Bournemouth, 392; at Leonardlee, 194; grafting, 80; Messrs. J. Waterer & Sons' exhibition of, 352; new, 313; parents of hardy hybrid, 416; shows, 217
 Rhubarb, and mice, 48, 64; forcing by amateurs, 53
 Roadways, Haslemere, Orchids at, 242
 Ridley, H. N., botanical expedition to Lower Siam, 361, 383, 406
 Roadside fruit trees, 9
 Rocco Longa, the home of Daphne nymphaea, 148
 Romance of a Clover, 139; of a grass, 113
 Root pruning in market gardens, 99
 Roots and soil, 40
 Rosa hendersonii, 418
 Rosary, the, 2, 19, 35, 63, 101, 114, 145, 187, 210, 253, 295, 315, 342, 364, 382, 417
 Rose canker, 343
 Rose disease, a mysterious, 343; a serious, 245
 Rose show at Berlin, 217
 Roses: Baron Job and Paul's Single White, 101; Beante de Lyon, 364; Henriette de Beauvean, 23; Jubet, 382; Marcella, 251; President Taft, 101; Rayon d'Or, 140, 210; Spidire, 101; William Allen Richardson, 417
 Roses: a trial of at Bagatelle, 169; basket of, presented to Queen Mary, 423; crimson colored, 55;

difficult, 19; for foliage, 321; fragrant, 315; hybrid Wichuriana, 5; novelties in, 26; some dwarf-growing single, 145; some very dark coloured, 35; supports for weeping standard, 203; the classification of garden, 225; the effect of the sun on the colour of, 421; the pruning of, 129; the pruning of China, 194; the pruning of Hybrid Tea, 161; the pruning of Noisette, 194; the pruning of Tea, 193; under glass, 2, 68, 115, 259, 343
 Rothamsted Experimental Station, bio-chemists meeting at, 410
 Royal Academy, pictures at the, 289
 Royal Cornwall Show, St. Austell, 412
 Royal Horticultural Society: Committee's visit to East Burnham Park, 371; Journal, 123; Medal awards, 418; Olympia Show, 72, 89; School of Horticulture, 89

 Royal Warrants for nursery and seed firms, 75, 90, 105, 121, 153, 153, 169, 185
 Rubber exhibition at the Agricultural Hall, Islington, 371

S

ST. JAMES'S PARK and the proposed memorial to King Edward, 200, 217
 St. John's Nursery, Worcester, sale at, 153
 St. Tudy, shrubs in flower at, 59
 Sale of Oak timber, 74
 Sandalwood tree, the, 20
 Sanders, T. W. (*Garden Vees*), 115
 Santalum album, the Sandalwood tree, 20
 Sargent, Prof. Charles S., awarded the "White" medal, 11; Irish honour for, 202
 Saxifraga aizoon baldensis, 251; S. × Clibranii, 123; S. Elizabethae, 250; S. × Haagii, 345; S. × kesoniensis at Monneith, 74; S. laevis, 345; S. lingulata and S. lantoscana 65; S. × pungens, 343; S. × Obristii, 228; S. × Sundermannii, 228
 Saxifrages, new hybrid, 345
 Saughton Park, Edinburgh, 53
 Saunderson, Mr. J., presentation to, 264
 Scab, varieties of, in Potato, 186
 Scale on Peach trees, to destroy, 288
 Schlich, Sir W. (*Manual of Forestry*), 216
 School gardens in London, 105; in Staffordshire, 105
 SCIENTIFIC COMMITTEE:—Achillea millefolium var. rubra, 124; Aleyrodes and scab insects attacked by a fungus, 221; Asparagus, fasciation in, 317; Azalea gall, Exobasidium japonicum, 59; Bean seeds, coloration of, 59; beetle boring bark of Pinus austriacus, 158; Begonias, sporting in, 30; Botrytis cinerea on Jasminum, 221; Brassica, fasciation in, 158; Cecidomyia salicis on Willow, 158; Cedar cones, 94; Celery, a disease of, 190; certificates to plants of scientific interest, 190, 221; cones, Cedar, 94; Crocus Imperati, a white form of, 94; Crocus sport, 221; Daffodil sport, 285; Daffodils, twin-flowered, 317; Dasylium glaucophyllum, 124; Elm trees, sap exudation in, 59; Exobasidium japonicum, Azalea gall, 59; Fungus disease of insect pests, 221; Galanthus, a fine, 124;

Galanthus, hybrid, 158; gall on Willow, 158; Gongora, a new species of, 285; G. Tracyana, 316; Hymenocallis festalis, 317; H. macrostaphana, 124; Hippeastrum, a hybrid, 158; H. calyptratum, 158; Iris pumila attacked with "rhizome rot," 394; Jasminum primulinum diseased, 221; Lopezia racemosa, 153; Mandevilla suaveolens, fruits of, 30; Narcissus cyclamineus × N. minimus, 158; Odontioda × Craveniana, 124; Odontoglossum, a malformed, 316; Oneida Routhledgei, 285, 316; Orchid, a fasciated, 153; Pear crossed with Quince, 285; Phragmites communis, cutting the reeds of, 94; Pineapples with rotten cores, 30; Pinus austriaca attacked by Hyabastes ater, 158; Polypodium vulgare var., 124; Primrose, a green-flowered, 190; Primula malacoides, fasciation in, 158; P. sinensis (stellata), abnormalities in, 190; Primroses, double-flowered, 285; Pyromia × Sedemii, 221, 285; Quince crossed with Pear, 285; Rhododendron concinnum, 317; R. Fargesii, 221; R. grande, 190; R. Pengaer, 285; R. rufescens, 317; Richardia africana with a double spathe, 94, 158; Rosa hemisphaerica, 394; Sap exudation in Elm trees, 59; Saxifraga × Bursiculata, 158; Septoria petroselinii var. Apii, a disease of Celery, 190; Snowdrop, a fine, 124; Sporting in Begonias, 30; Tulip disease, 317; Variation in Wheat, 124; Viburnum Davidii, 317; Wallflower, fasciation in, 124; Wheat, variation in, 124; Willow, galls formed by Cecidomyia salicis on, 158; Sclerotinia disease of Mangolds, 329; Sclerotinia fructigena on Plums, 324
 Scotland, notes from, 9, 42, 58, 74, 91, 132, 165, 188, 210, 233, 245, 261, 293, 307, 367, 354, 391, 415; forestry in, 265
 Scottish gardeners, bequests to, 28
 Scott, Dr. D. H. (*The Evolution of Plants*), 367
 Scum on ponds, 340
 Sedum pilosum, 347
 Seed pans, retaining moisture in, 261
 Seed protector, the Dunsmore, 121
 Seed selection, 139
 Seeds, protecting, 121
 Seed-sterilisation by formalin, 265
 Seeds of Chinese trees and shrubs presented to Kew Gardens, 371
 Shetland, gardening in, 28
 Shill, Mr. J. E., appointment of, 8
 Shirley Poppies, 394
 Shrubs, forced, 156; in flower at Kew in October, 9; in flower at St. Tudy, 59; poisonous, 13; spring-flowering, 154; winter-flowering, 93
 Siam, Lower, a botanical expedition to, 361, 383, 406
 Simple life, conference and exhibition on the, 57
 Singapore, note from, 386
 Skin irritation from Ivy, 139, 157, 170, 190
 Small holdings, exhibition of, 57; Peterborough County Council refuse to provide, 41

NOVELTIES OF 1910.

A CONSIDERATION of the Orchids certificated by the Royal Horticultural Society during 1910 clearly indicates that the hybridist and the importer of natural species have shared the honours in fairly equal proportions. It may also be noted with pleasure that many species of the class usually denominated "botanical," to distinguish them from the more showy sorts, have been presented at the exhibitions by such renowned growers as Sir Trevor Lawrence, Bart., K.C.V.O., Sir Jeremiah Colman, Bart., and Messrs. Sander & Sons.

The hybridist has produced some excellent Cypripediums, Cattleyas and Laelio-Cattleyas, but no new hybrids have been obtained of sufficient merit to distinguish them from the general collection. The Odontoglossums which have furnished beautiful hybrids in several previous years have been less productive of novelties possessing superlative merit.

Lieut.-Col. Sir GEORGE L. HOLFORD, K.C.V.O., Westonbirt (gr. Mr. H. G. Alexander), has led by a long way in the matter of showing, this being true both in the quality and in the number of his certificated plants. His honours include nine First-class Certificates and 18 Awards of Merit. The certificates were awarded for Cattleya Dusseldorfii Undine and C. Robert de Wavrin, both Westonbirt varieties; C. Warszewiczii Low's variety, of very fine colour, and Lycaste Skinneri hellebensis, the largest and richest coloured Lycaste; Orlontioda Bradshawii Westonbirt variety, like a scarlet flaked Orlontoglossum; Cypripedium Minotaur and C. Shogun; Laelio-Cattleya Berthe Fournier magnifica, and Vanda corulea "Westonbirt variety." This Westonbirt variety of Vanda corulea, like its companion V. corulea "Bluebeard," which received an Award of Merit on December 6, has flowers almost entirely of a bright indigo-blue. Other Westonbirt Orchids which received Awards of Merit were Cypripedium Atlas and C. Pantum, both good and distinct hybrids; Cattleya Miranda "Westonbirt variety," C. Hardyana Holford's variety, C. Ardens, C. Dree magnifica, C. Warszewiczii Othella, C. Pauline, and C. Percivaliana "Westonbirt variety." Cypripedium Dante rotundilobum; Laelio-Cattleya Goldfinch "Westonbirt variety," and L.C. Golden Oriole variety, both these Laelio-Cattleyas having yellow flowers suffused with red; L.C. Ortrude magnifica, L.C. Olivia; Miltonia vexillaria "Snowflake;" and Odontoglossum crispum "Magnum Bonum." All these plants, like others staged by Mr. Alexander, were fine examples of good culture, and in several cases Cultural Commendations were awarded by the Orchid Committee.

Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. W. H. White), constant in his partiality for pretty species, although not unminimally of the claims of the hybrids, showed about a dozen interesting and rare species, which gained Botanical Certificates. Megacalanium triste, M. fuscum, Bulbophyllum Rhizophora and Polystachya paniculata were singular species from Africa; Dendrobium Karwinskii and Bulbophyllum polyblepharis were miniature curiosities of great interest; B. exaltatum had sprays of feather-tipped flowers. Lyparis rhodochila bore erect spikes of small flowers with orange-scarlet lip. Other certificated plants included Dendrobium Bullianum, Theclora gomezoides and Polystachya bracteosa. Or hybrids, Sir Trevor Lawrence exhibited some very good crosses of Dendrobium signatum with yellow flowers of an uncommon tint, and several Cattleyas and Laelio-Cattleyas; Awards of Merit being awarded for L.C. Trinyra and Epi-Cattleya Nebo. In the matter of fine growth, his clever Orchid grower, Mr. W. H. White, received Cultural Commendations for Habenaria Uganda, Scrochilus Hartmanni, Oncidium incurvum (for a specimen cultivated at Burford for over 25 years), Platyclinis filiformis, Dendrobium Hookerianum and Lycaste costata.

Sir JEREMIAH COLMAN, Bart., V.M.H., Gatton Park (gr. Mr. Collier), also favouring both species and hybrids, with a leaning towards rare species, has a good record to his credit for plants shown before the Orchid Committee. He received an Award of Merit for Calanthe densiflora, a fine yellow species, and Botanical Certificates for Dendrobium arcuatum, a pretty and distinct Javan species, probably not in any other collection; Dendrobium speciosum nitidum, the large specimen shown having 46 spikes, and gaining another Cultural Commendation to several similar awards Mr. Collier has won during the year, and Dimris longifolia, a yellow and purple Australian terrestrial. During the past year, some interesting hybrids of Dacryma bicolor-

tum, Spathoglottis, Sobralias and Dendrobiums raised at Gatton Park have been shown, Awards of Merit being obtained by Dendrobium Duchess of Albany and D. Mrs. Arnton Fenton, both fine productions, and Odontoglossum Thompsonianum "Gatton Park variety."

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), whose collection is rich in showy Orchids, secured First-class Certificates for Cattleya Rhoda "Fairlawn variety," and C. Iris "King Edward VII.," both among the finest coloured hybrids of their class, and Awards of Merit for Orlontioda Goodsoniae of a rich scarlet colour, Orlontoglossum Ceres "Goodson's variety," and Cattleya Schroderae "The Prince." Mr. Goodson showed the richly coloured Sophro-Laelio-Cattleya Alethica and other good hybrid Orchids at most of the meetings of the year.

J. GURSEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), received Awards of Merit for Odontoglossum Arnoldianum, a pretty hybrid, and Catasetum fimbriatum aureum. Among other novelties, he showed the prettily-spotted Odontoglossum ardentissimum "Starlight," the finely coloured Sophro-Laelio-Cattleya Olive and the handsome Cypripedium Priscilla.

DE BARR CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), has shown many new Odontoglossums during the past year, his very fine Orlontioda Charlesworthii "Theodora" gaining a First-class Certificate. The new Orlontioda gattoniensis rosefieldensis (the type of which was first shown by Sir Jeremiah Colman, Bart.) and Odontoglossum regale rosefieldense secured Awards of Merit, while the quaint beauty of Orlontioda Senenaca (C. Neesiana x O. Hunnewellianum) seemed to promise a desirable hybrid when it is matured.

H. J. BROMLOW, Esq., Rann Lea, Rainhill, Lancashire (gr. Mr. Morgan), a great lover of good Cypripediums, secured Awards of Merit for C. Lord Wolmer, C. Lecanum Excelsior, and C. Reginald Young, all fine hybrids, well worthy of Mr. Bromlow's collection; F. MEXTETH OGLVIE, Esq., Oxford, obtained a First-class Certificate for Lycaste Skinneri armeniana; His Grace the Duke of Marlborough (gr. Mr. G. Hunter) showed Laelio-Cattleya limosa magnifica, TARBOT CLIFFES, Esq. (gr. Mr. Floate), L.C. Aphrodite "Mark Hambourg," W. P. BURKINSHAW, Esq., Healy, Hull, obtained a First-class Certificate for Miltonia vexillaria "Hesse variety;" Mrs. NORMAN COOKSON, Oakwood, Wylam (gr. Mr. H. J. Chapman), a First-class Certificate for Orlontioda ardentissimum "Norman Cookson," and Awards of Merit for the pretty Cypripedium Angela, and the large white Orlontioda Cooksonae gigantea.

Mrs. BISHOFFSHEIM, The Warren House, Stanmore (gr. Mr. Taylor), obtained a Botanical Certificate for a blue Disa of great interest—Disa mustii, and this has been crossed with D. grandiflora in the Warren House Gardens with success; J. S. BERGHEIM, Esq., Belsize Court (gr. Mr. H. A. Page), gained a Botanical Certificate for Angreocum pellucidum, and GRANEY WILSON, Esq., a similar award for Pleurothallis ardentata.

R. G. THWAITES, Esq., Chislington, Streetly, Loughborough (gr. Mr. J. M. Black), reiser of the beautiful scarlet Sophro-Cattleya Dora, the mauve-tinted Orlontioda Thwaitesii, and many

other fine hybrids, received Awards of Merit for Cattleya Adula "Thwaites' variety," a finely-coloured hybrid, and Odontioda Cecilia, a very distinct flower with cream-white ground and red markings.

WALTER COBB, Esq., Normanhurst (gr. Mr. C. J. Salter), was awarded a First-class Certificate for *Sophro-Cattleya Doris* "Cobb's variety," the largest and best scarlet *Sophro-Cattleya*; and an Award of Merit for *Odontoglossum Lawrenceanum* "Cobb's variety."

WILLIAM THOMPSON, Esq., Walton Grange, Stone (gr. Mr. Stevens), scored with *Odontioda Vuylstekeae* "Walton Grange variety;" H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), with *Cymbidium Lowgrinum* "Rosslyn variety;" SAMUEL LARKIN, Esq., Haslemere (gr. Mr. Hale), for *Cattleya lucida*, a very pretty and floriferous hybrid; and W. R. LEE, Esq., Plumpton Hall, Heywood, gained Awards of Merit for the fine reddish-claret-coloured *Odontoglossum Rouge Dragon* and *O. Ceres* "Plumpton Hall variety."

A pathetic interest attaches to the fine claret, purple-lipped *Phaio-Calanthe Schröderiana* raised at the Dell Gardens by Mr. Ballantine, and for which a First-class Certificate was given on March 8, it being the last Award given during the lifetime of Baron Schröder.

NURSERYMEN.

MESSRS. SANDER & SONS, St. Albans, both in the number of the awards obtained and in the quality of their exhibits, stand first in rank amongst nurserymen exhibitors. This firm secured First-class Certificates for *Vanda cœrulea Sanderæ*, the first variety with pink flowers; *Phalenopsis casta superbissima*, one of the best natural hybrids; *Odontoglossum splendens* and *O. Memoria King Edward VII.*, both fine enough to satisfy the most exacting taste; *Miltonia vexillaria Lambeauiana*, M. v. *Memoria Baron Schröder*, one of the attractions of the Temple Show; *Cypripedium "Princess Mary"* (*C. niveum* × *C. Helen II.*), and the large and handsome *Cypripedium Charlesworthii Temeraire*. Awards of Merit were recommended for *Phaius Cooperi*, which also obtained a Botanical Certificate; *Oncidium Sanderæ*, a distinct addition to the class of Butterfly Orchids; the white *Houlletia Sanderæ*, *Sobralia Cliftonii*, *Lycaste peruviana*, *Cypripedium Curtisii* "Sanders' variety," the largest and richest coloured yet shown; *Cattleya Triamæ* "Magali, Sander," *C. Mendelii* "King George V.," *C. Dietrichiana*, *Odontoglossum Black Prince*, *O. eximium* "Emperor," and the showy *Cypripedium Britannia*. *Bifrenaria bicornaria* and *Brassia Forgetiana*, two interesting species, gained Botanical Certificates.

MESSRS. CHARLESWORTH & CO., Haywards Heath, Sussex, on January 25, were awarded a First-class Certificate for *Anguloa Cliftonii* with citron-yellow flowers marked with violet-purple and quite distinct from any other species. At the Temple Show the firm gained a similar award for *Cattleya Lawrenceana* "Mary Regina," the first albino of this species, and *Sobralia Ruckeri Charlesworthii*. An Award of Merit was given at the Temple for *Cattleya Mendelii* "Queen Maud," and similar awards at other times were obtained for *Odontoglossum Ceres*, whilst the variety "magnificum" gained a First-class Certificate at the last meeting of the year. Further Awards of Merit were granted for *Odontoglossum Cravenianum*, *O. Ceres*, *Disa lacera multifida*, *Pescatorea lamellosa*, which appears not to have been shown before; *Cattleya Linegea*, *C. Basil*, *Sophro-Cattleya Hon.* Barbara Wilson, a very finely-coloured and distinct flower; and *Miltonia Warszewiczii leucocila*. A Certificate of Appreciation was awarded for the very remarkable hybrid *Oncidioida Charlesworthii* (*Oncidium incurvum* × *Coelioda Noezliana*), a singular cross which, like others raised by Messrs. Charlesworth,

were thought to be impossible only a few years ago.

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nurseries, Chelsea, showed many interesting hybrids, especially *Cypripediums*, one of the best being *C. Iolanthe*, which gained an Award of Merit on November 22.

MESSRS. STUART LOW & CO., Bush Hill Park, constant exhibitors of good things, were awarded First-class Certificates for *Cattleya Mendelii* "Stuart Low," one of the best of pure white *Cattleyas*, and *C. O'Brieniana alba*, an equally good albino. Messrs. Low & Co. were also awarded Botanical Certificates for *Stanhoepa saccata* and *Cyrtopodium Andersonii*, not new, but interesting, plants.

MESSRS. J. & A. A. McBEAN, Cooksbridge, the great *Odontoglossum* growers, received Awards of Merit for *Odontoglossum Gladys* "W. H. Cheal," an elegant and showy hybrid; *Miltonia Phalenopsis* "McBean's variety," large and of fine colour, and *Cattleya Mendelii* "Pearl McBean." They also showed *C. Dowiana alba* and *Odontoglossum Ardentissimum* "Doris," which were exceptionally good.

Mr. E. V. Low, Vale Bridge, Haywards Heath, obtained a First-class Certificate for *Cypripedium King George V.*, which was pronounced to be one of the finest *Cypripediums* of the year, and Awards of Merit for the scarcely less stately *C. Waterloo* and *Oncidium Mantinii Lowii*.

MESSRS. MANSELL & HATCHER, Rawdon, Yorks., secured, at the Temple Show, a First-class Certificate for the very pretty white, rose-tinted *Cattleya Mendelii* "Princess Victoria."

CONTINENTAL EXHIBITS.

Mons. CHAS. VUYLSTEKE, Loochristy, Ghent, showed some grand hybrid *Odontoglossums* at the Temple Show, and four of these received awards, but, unfortunately, the flowers were not given to the R.H.S. for the purpose of painting, therefore, the awards were withheld.

The following new and noteworthy Orchids have been illustrated in the *Gardeners' Chronicle*, during 1910:—

- Bulbophyllum Binnendijkii*, Feb. 5, p. 84.
- Calanthe lilacina*, Jan. 29, p. 66.
- Cattleya Emil Karlhausi*, Supp. May 28.
- Cattleya Mendelii* "Stuart Low," July 15, p. 35.
- Cattleya Rhodia* "Fairlawn variety," Sept. 3, p. 174.
- Cattleya Portia* "Larkins variety," Nov. 26, p. 386.
- Cattleya Warszewiczii alba*, July 16, p. 34.
- Colognye Lawrenceana*, May 21, p. 335.
- Cypripedium Charlesworthii Temeraire*, Dec. 10, p. 424.
- Cypripedium Gaston Bultel*, Dec. 31, p. 485.
- Cypripedium King George V.*, Dec. 17, p. 412.
- Cypripedium Minotaur*, Dec. 10, p. 425.
- Cypripedium Britannia*, Nov. 5, p. 331.
- Cypripedium Princess Mary*, Nov. 5, p. 330.
- Cypripedium Mrs. F. Sander*, Jan. 8, p. 19.
- Cypripedium Reginald Young*, Dec. 3, p. 406.
- Cypripedium Shogun*, Oct. 1, p. 250.
- Cymbidium Dunlop-Lowianum*, June 18, p. 407.
- Cymbidium Dundas of Albany*, Feb. 26, p. 139.
- Dendrobium Mrs. Fenton Arntson*, Mar. 5, p. 119.
- Eria phycostylodes*, June 11, p. 378.
- Laelio-Cattleya Deceatiana*, Oct. 15, p. 274.
- Laelio-Cattleya Berthe Fournier* "magnifica," Sept. 17, p. 250.
- Laelio-Cattleya Olivia*, Dec. 10, p. 431.
- Laelio-Cattleya Walter Gatt*, Nov. 19, p. 375.
- Miltonia Blenana* "Queen Mary," May 28, p. 351.
- Miltonia vexillaria Snowflake and virginala*, Supp. Sept. 17.
- Miltonia vexillaria "Memoria Baron Schröder"*, May 28, p. 375.

A review of the work of the past year takes the mind back to the much earlier days of Orchid hybridisation, when Messrs. Jas. Veitch & Sons produced good batches of the handsome *Laelio-Cattleya Canhamiana*, *L.-C. Dominianum*, and many others which are still amongst the best hybrids. If these are compared with subsequent productions in the same class, and especially with those raised during the past year, it proves that Messrs. Veitch had some justification for despairing of ever raising future hybrids of greater floral beauty.

(To be continued.)

THE ROSARY.

CULTURAL NOTES FOR JANUARY.

THE mild weather and general humidity of the season caused a late ripening of the shoots, and cuttings of many varieties may still be rooted. This applies especially to the Wichuriana varieties, and the strong-growing Tea and China Roses. Suitable shoots of almost all sorts of the dwarf-growing *Polyantha* type may still be rooted, although it would have been better to have inserted them earlier in the season. *Crimson Rambler*, *Blush Rambler* and *Dorothy Perkins* with its numerous sports, may still be increased from cuttings; in many cases the wood was none too ripe for the purpose before this date. Frau Karl Druschki, Conrad Ferdinand Meyer, and its sweet-scented white sport *Nova Zembla*, strike from cuttings as freely as the Brier and Manetti stocks. Do not remove the lower buds, as is done with shoots intended for stocks, for the sucker-like growths resulting from these will form the most valuable part of the plant. It is well to insert the cuttings deeply, leaving only about an inch out of the ground, as the soil will be sure to sink considerably.

All arrears of planting should have been finished, otherwise it will be better to delay the work until the end of February, or the most favourable time in that month. Planting on wet and soddened ground should be avoided as far as possible. Planks or wide boards are very serviceable when planting in freshly-trenched ground, especially during a wet season such as the present one.

Much good will result by cutting away superfluous wood from Roses trained on arbours and pergolas during suitable weather in January, thus lessening the work during the ordinary pruning season, and exposing the shoots to the light and air. Sufficient importance is not usually attached to the cleansing of the stems of old standard Roses. Oftentimes these are infested with mosses and lichens, which may be removed if the bark is rubbed with a piece of coarse sacking, using the back of the knife to scrape the main branches near to the stem. If, in addition to this, the plants are dusted over with a little fresh lime, the cleansing will be more complete. Great advantages also result from lifting and replanting old and deteriorated standard Roses. Frequently a plant is unhealthy through exhaustion caused by the presence of sucker-like roots, which need to be cut away.

It often happens, too, that a few standards are killed by frost in early spring, notwithstanding they have apparently passed through the winter unharmed by cold. But the late frosts often have the worst effect on standard Roses, especially those with stems that are hidden to such an extent that the sap cannot circulate freely. Where standard plants fail, they leave a gap that is difficult to furnish, and I would recommend that a few plants be potted up at once and plunged in a cool, sheltered border for filling up such blanks at pruning time.

ROSES UNDER GLASS.

January is one of the most important months in the Rose house, for great care and attention will be needed to keep the plants healthy. Often there is a regrettable delay in using remedies against mildew and insect pests. Mild measures will do if they are adopted early, and will be less harmful to the tender shoots. It is far better to give two or three weak applications of any specific than one powerful dose that may harm the tender growth. Flowers of sulphur is not used so largely as it should be in most insecticides, and I would advise a little more of this to be stirred in the various specifics used for syringing. Always keep the solution well stirred during its application, so as to get a slight deposit

of sulphur on both surfaces of the foliage. The affording of proper ventilation is an important detail in growing Roses under glass, and especially at this stage. It sometimes happens that the fires are mended too late in the morning to secure the requisite heat before the sun becomes powerful. This necessitates ventilation, which exposes the plants to a chill early in the morning. Liquid manures should not be given until the plants are in an active condition of growth; nor is it wise to use strong doses of liquid fertilisers, it being better to apply them weak and more often. Mildew is not always caused by draughts; my own observations have convinced me that it follows a check of any kind. Dry conditions at the roots, or the use of strong stimulants, may cause a predisposition in the plants to

favour as this type. An exceptionally fine effect has been produced in a remarkably short space of time at Aldenham House Gardens, where an iron fence 4 feet high and fully a quarter of a mile long has been covered mainly with these Roses; the neat growth and glossy green foliage of the plants form an admirable covering for a fence of this description. One of the best is Dorothy Dennison, a pink sport of Dorothy Perkins; the plant is free in flowering, and a vigorous grower, the blooms lasting fresh for a long time. White Dorothy is also a valuable variety, as it is later coming into flower than any others of the type. Mme. Alice Garnier is another desirable sort, the blooms being pale pink on a yellowish ground, and they are produced from July until October. Other excellent varieties include Alberic Bar-

ORCHID NOTES AND GLEANINGS.

BULBOPHYLLUM CYLINDRACEUM.

At the meeting of the Royal Horticultural Society on December 5 last, Messrs. Sander & Sons, St. Albans, exhibited the curious species, illustrated in fig. 1. It is the *Bulbophyllum cylindraceum* of Lindl. *Gen. et Sp. Orch.*, 53; *B. Khasyanum* Griff. *Notul.* iii., 284, and *B. imbricatum* of the same author, 289. The last name has been applied to it in English gardens, although the *B. imbricatum* Lindl. is a tropical African species, whereas *B. cylindraceum* is Indian, the plant illustrated being imported from Burma. This locality is not given in *Flora of British India* v., 765, whilst the

FIG. 1.—BULBOPHYLLUM CYLINDRACEUM: FLOWERS COLOURED PINK TO DEEP PURPLE.

become affected. Liquid manure may be given freely to plants that are root-bound, but it should not be applied to newly-potted plants until the roots have thoroughly permeated the fresh soil. Maintain an atmospheric temperature as near to 50° at night time and 65° at midday as can be managed, never hurrying the plants until growth is active. Undue haste in the early stages of forcing is often responsible for "blind" or flowerless growths. *Practice.*

HYBRID WICHURAIANA ROSES.

In addition to the varieties named by *A. P.* (see vol. xlviii., October 8, p. 261), the sorts enumerated below are deserving a place in any collection. As *A. P.* states, no other section of climbing Roses has advanced so quickly into

bier, creamy-white to canary-yellow with darker yellow buds; Pink Roamer, having exceptionally showy silvery-white blooms, the single flowers being freely produced; René André, a shade of saffron-yellow with red buds; Sweetheart, pure white, small double blossoms, showing to advantage against the dark foliage; Excelsa, crimson; Cougina, pink; and Shower of Gold, of the shade found in W. Allen Richardson but paler.

I was pleased to see *A. P.* refer favourably to *Gardenia* in a recent issue. I have long regarded this Rose as very valuable, both for the charming buds, which are of a rich yellow tint, and for the continuous manner in which the blooms are produced from June until November. *E. M.*

species is recorded as non-Burman in Grant's *Orchids of Burma*. Its pseudo-bulbs are rudimentary, and in habit the plant resembles *B. spathaceum*. The flowers are curiously flattened and closely arranged. They vary in colour in different plants from pink to deep purple; those of the specimen illustrated having a whitish ground heavily marked with deep claret-purple. An interesting feature in the structure of the flower is the manner in which the tip of the upper sepal curls back as the flower approaches maturity, thus opening up the passage over the labellum to the column and facilitating pollination by insects visiting the flower in search of food. The species is not showy, but the structural arrangement of the flowers will amply reward those who examine them with a good lens.

NOTICES OF BOOKS.

ORCHIDS.*

(See Supplementary Illustration. Coloured Plate.)

THERE are numbers of people anxious to attempt the culture of Orchids. Mr. James O'Brien's volume will encourage them, first, by proving that Orchids, like other plants, are capable of being understood by anyone who really desires to understand them; and, secondly, that when once understood, the cool species, at any rate, are not less tractable than common greenhouse plants. So much is this the case, that the author of this book declares that even the householders in suburban districts who have but one conservatory, may, if they choose, keep that structure furnished with Orchids at a less expenditure of time and money than is necessary for the Palms, Ferns, and other species usually employed for the purpose.

Chapter I. is devoted to an account of the rise and progress of Orchid culture. Commencing in 1735, with *Bletia verecunda*, which was the first exotic Orchid to flower in the British Isles, the important dates are enumerated and historical notes given in a clear and brisk style.

Following a short account of the structure of Orchid flowers, and a chapter on the difficulties to be overcome in respect to cultivation, there is a chapter on the structure of the Orchid house. One of the notable improvements in structure is warmly commended by Mr. O'Brien, namely, the abolition of all side glass and hinged ventilators on a level with the plants. The greatest success in growing Orchids has been obtained in houses where the brick side-wall is carried up to the eaves, and the floor is formed of the natural earth covered with an open wood-work trellis. Short articles on the methods of heating, the best kind of staging, and the various means of preventing the sun's rays from scorching the plants are given in a manner which the amateur will appreciate.

The uses of baskets and pots and the methods of staking and fixing Orchids are explained in detail, and amateurs are warned, when watering suspended pots or pans, not to allow the water to drip on to other plants. It is just as necessary to warn them against the somewhat common habit of allowing suspended plants to become so dry as to greatly hinder their power of growth.

Amateurs will get much information from the remarks on watering. The danger of applying manures cannot be impressed too much on the mind of the grower. Unless the subject is thoroughly understood and the practice carried out by experienced hands, failure will more probably result than success. Mr. O'Brien's statement that no Orchid grower should undertake manual experiments without first obtaining his employer's concurrence is worthy of special note.

The treatment of resting Orchids is often misunderstood, the term "resting" being taken to mean either a severe drying off which causes shrivelling, or the placing of the plant in an out-of-the-way spot where there is little chance of it receiving attention. The correct manner of resting Orchids and the treatment of specially rare plants is fully dealt with in this book, which, although written mainly for amateurs, contains much that will prove useful to more advanced growers.

In respect of the treatment of freshly imported non-pseudo-bulbous plants, it is probable that more imported plants are killed through over-attention than neglect. Mr. O'Brien recommends a treatment that appears at first sight somewhat drastic, but the method has much to recommend it. He says: "But good results, and a quicker establishment may be secured, if the plants are recoverable, by immersing them for five minutes in a

rain-water tank immediately on arrival, suspending them head downwards from the roof of the house afterwards, and repeating the dipping two or three times a week. This method has the advantage at least that those which were not recoverable are quickly discovered, while the sound plants soon plump up."

During the last 50 years, an increasing desire to raise seedlings has caused many to examine more fully the structure of the flowers. Those anxious to make their first attempt at cross-breeding may acquire all the necessary information from the chapters devoted to hybridising, seed-raising, and treatment of seedlings.

There are eight excellent coloured plates, reproduced from photographs, and each represents a first rate specimen in the collection of Lieut.-Col. Sir George Holford, K.C.V.O., at Weston-

ever-popular species *Odontoglossum crispum* is represented by a plate showing two well-flowered spikes.

One of the finest specimens of colour photography yet seen is the plate of *Brasso-Cattleya Digbyano-Mossie* "Westonbirt variety." The plant bears seven grand flowers, and they are depicted in the exact shade of colour. This plate alone is worth the small sum charged for the volume. *Gurney Wilson, F.L.S.*

[We are indebted to Messrs. T. C. & E. C. Jack for permission to reproduce the plate which forms the Supplementary Illustration to this issue.—Eds. *Gard. Chron.*]

APICE TUBEROSA.

THIS is a very elegant, little, hardy, twining perennial, bearing, in autumn, clusters of sweet-scented brownish-purple flowers in axillary racemes. It is very little known outside botanic gardens, but nothing could be more charming for an odd corner where a twiner is needed. In the herbaceous grounds at the Botanic Garden, Cambridge, supported by a few sticks, it grows to a height of about 5 feet, and is 5 feet through. It does best in an open position, and is increased quite easily by division of the tubers. The tubers are numerous, farinaceous, and edible, and, on account of them, the plant is sometimes known as the "Ground Nut." The native habitat of the plant extends from Pennsylvania to Carolina. For the accompanying photograph (see fig. 2) I am indebted to Mr. E. J. Allard. *R. Irwin Lynch.*

THE MARKET FRUIT GARDEN.

THE PAST YEAR.

FOR the fruit farmer, the reminiscences of 1910 are, in many respects, unpleasant. He calls to mind the spring frosts which seriously damaged the Gooseberry and Black Currant crops, and the prevalence of strong winds from the north-east, or a similarly cold quarter, which prevailed during the blossoming season of Pears, Cherries, and Plums, doing far greater damage than the frosts. There has seldom been a more miserable Pear crop, Cherries were very scarce, and Plums, on the whole, were not half an average. The grower calls to mind the capricious blossoming of Apples, and the more remarkable dropping of embryo fruits after they had set, both probably attributable mainly to the sunless character of the preceding season. The Apple crop, on mature trees, however, turned out less deficient than the expectations entertained at midsummer. At least, this is the conclusion drawn from the state of the markets, where the prices of Apples were very little higher than they are in a season of moderate abundance. Other kinds of fruit, on the contrary, realised better prices than usual.

With respect to fruit pests, the year was remarkable for a great measure of exemption from attacks of the leaf-curling aphid, and for an almost complete absence of wasps. Fungous attacks were about as usual. There was a good deal of brown rot among Plums, but less of this disease on Apple trees than occurred in 1909. The scab fungus has often been more in evidence in Apples than it was last year, although the legacy left by the very wet portions of the year is to be seen too plainly on the young wood of some varieties.

As for the autumn and early winter planting seasons, the land was sodden with the heavy rainfall of November and the first 16 days of December. On the whole, fruit growers were glad to bid farewell to 1910.

A RAINFALL RECORD.

The following is a record of the rainfall of 1910 at my station in the southern part of the south-

FIG. 2.—APICE TUBEROSA: FLOWERS PURPLISH-BROWN.

birt. The quality of these may be judged by the supplementary illustration to this issue.

Cypripedium insigne Sandrae is depicted with 18 flowers, and *Dendrobium Wardianum* with 264 flowers. One of the most beautiful plates is *Miltonia vexillaria* "Empress Augusta Victoria," a noble plant, cultivated from a single growth, and bearing 126 flowers—an instance of exceedingly good cultivation. *Cattleya Trianae* var. *Hydra*, a good winter-blooming plant, is shown with 83 flowers. *Cymbidium Lowii-churnum* is represented with numerous flowers, and the specimen has been commended for its good culture by the Orchid Committee of the Royal Horticultural Society on two separate occasions. Those who are fond of the yellow *Oncidiums* will find a splendid example in *Oncidium Marshallianum*, which looks like a shower of golden butterflies, while the

* *Orchids*, by James O'Brien, V.M.H., Vol. V, in a uniform series called *Present-Day Gardening*. (T. C. and E. C. Jack, Edinburgh and London.) Price 1s. 6d.

east of England, where the quantity in October and November was much greater than in most other parts of the country:—

Month.	No of Rainy Days.	Fall in inches.
January ...	16 ...	3.56
February ...	22 ...	4.28
March ...	6 ...	1.52
April ...	17 ...	1.84
May ...	16 ...	2.04
June ...	13 ...	2.28
July ...	12 ...	2.28
August ...	16 ...	1.72
September ...	3 ...	0.30
October ...	13 ...	3.69
November ...	14 ...	6.14
December ...	14 ...	3.65
Totals ...	162 ...	35.50

In 1909 the total was 34.54 inches, and in 1903 it was 37.95 inches; but in the rest of the eight years preceding 1909 the range was only 19.32 inches to 29.35 inches. My record extends for ten years, during which time the annual average was 28.11 inches.

KEEPING APPLES.

It might have been supposed that, if it ever pays to keep Apples, it would have paid well to keep them this season. Results indicate, however, that, unless a grower is prepared to keep his fruit until January, he might as well market them directly they are gathered. Fruits of Lane's Prince Albert marketed on September 10 made 5s. a bushel, and some which were kept until November 18 were sold in the same market at 6s. This was the best result of keeping, and, perhaps, it paid slightly, although the waste in weight must have gone far to reduce the extra profit. But, taking the Board of Agriculture's quotations for London, Warner's King firsts were quoted on September 15 at 5s. 6d. per bushel, and on December 1 at 6s. This was the latest date at which that variety was quoted. "Other cooking" Apples, firsts were quoted at 4s. 6d. on September 15, and at 5s. on December 15. Sixpence a bushel for keeping for three months, with all the risk of waste and damage from mice, can hardly be regarded as profitable. As it happened, Apples kept exceptionally well. The fruits of Lane's Prince Albert, for which I had only 6s. per bushel returned on November 18, with 6d. commission to deduct, were all large fruits. Beyond comparison, they were superior to any American cooking Apples, and yet the best of those latter, at the time, were making 22s. per barrel of three bushels. Probably those growers who have good Apples yet to sell will obtain higher prices before the end of the current month; but there seems to be a poor demand for English Apples when the markets are full of American fruits.

DELUSIVE COX'S ORANGE PIPPIN.

The word "delusive" is applied to this variety because it breaks its early promise. Nothing could have looked better than the trees raised by me a few years ago (some on the Crab stock and others on the donchin) as they stood in their nursery bed when two years from the grafting. They had been topped as maidens, and had branched out splendidly. After being planted in their final quarters and cut back sufficiently, they made vigorous growth. Some were planted five years ago, and others four years. This winter there was scab on the upper parts of the great majority of the shoots of last summer's growth, and these had all to be cut back more or less severely below the scabby parts. But this is not all, for a great many of the fruit spurs were cankered, and these also had to be sacrificed. Again, some trees, now 10 years from the planting, grew vigorously, and fruited well for two or three seasons after the third year; but in the eighth year they were injured by spraying, although the operation did not harm other varieties close to them in the slightest degree. They bore no fruit of any consequence

—only a few miserable little specimens—in the eighth and ninth seasons, and in 1910 they bore only about half a crop of small Apples. Two points seem to me essential to observe in growing this Apple. In the first place, unless the soil is a very fertile one, and not too heavy, profuse manuring is necessary; and, secondly, the trees must be well sheltered from wind. My young trees of this variety at the bottom of the field, where the soil is excellent, and where there is plenty of shelter, are very fine specimens; while those at the top of the field, near a sheltering hedge of great height, but on less good soil, are only fair trees. Those in the middle of the field, across which the south-west gales sweep, are greatly inferior. In respect of scabby wood, the stock on which the trees were raised does not appear to make any difference. Some of them are on the crab, some on the donchin, and some on the free stock, and scab development is about equal on all three lots.

ARRIERS OF PLANTING.

The last fortnight in December—or part of it—was the best time for planting enjoyed this season. The soil had been run into a compact mass by the deluge of the preceding six weeks, but it was firm and dry, instead of being waterlogged, as it had been before. A great deal of planting remains to be done, probably three-fourths of the acreage laid out for the operation in the country at large. Let us hope that there will not be a prolonged hard frost, or much rain or snow before this work is completed.

QUESTIONABLE ADVICE.

At the Fruit Conferences held in the latter part of last year at Hexham and Wye, some of the recommendations of varieties of Apples for market growers were astonishing. These varieties included King of the Pippins and Stirling Castle, two of the worst for canker, while Stirling Castle is of such a dwarf habit, and endowed with such a propensity to "crop itself to death," that it is one of the varieties which need extra expenditure in manuring. In my opinion, King of the Pippins is hardly worth growing anywhere, for, in a market plantation, its liability to be eaten up by canker condemns it, while the lack of flavour in its fruit renders it a negligible variety for a private orchard. Stirling Castle, if grown at all, is suitable only for a garden, where its dwarf habit of growth is a recommendation. Conversely, the warning against planting Worcester Pearmain, given at Wye, seems to me a mistake. It was described by two speakers as a worn-out variety; but I agree with Mr. Mount, a man of extensive experience, in classing it as one of the most profitable of Apples for the market grower, although I do not care to eat it. Mr. Mount condemned Gascoyne's Scarlet, without giving any reason. This variety is one of the most vigorous growers on my land, and a regular cropper; but I fear it is not a great bearer. The unqualified recommendation of non-returnable boxes, in place of salesmen's baskets, made by several speakers at Wye, seems to me a mistake. The expense is far too great for low-priced fruit, which forms the bulk of the consignments in a fairly productive season. Another recommendation with which I disagree is that in favour of the general adoption of the auction system for fruit. My experience shows that this system tends to the reduction of prices. *A Southern Grower.*

GARDENERS SILVER WEDDING.—Mr. and Mrs. G. DYKE, of Garston Manor Gardens, celebrated their silver wedding on Christmas Day. They received a present of a silver tea and coffee service, bearing the inscription: "Presented to Mr. and Mrs. G. DYKE, on the occasion of their Silver Wedding, December 25, 1910, from Mr. and Mrs. CLAUDE WATNEY, Garston Manor"; also a clock, from the Staff at Garston Manor and Charles Street, London.

The Week's Work.

THE HARDY FRUIT GARDEN.

By W. HILDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

MANURE FOR MULCHING.—The recent rains have necessitated the postponement of much of the work in this department, owing to the soddened condition of the soil. With the advent of more seasonable weather, these arrears must be wiped out, and the work pushed forward with all possible speed.

During frosty weather, advantage may be taken for wheeling out manure, in preparation for mulching all the autumn-planted trees. A like dressing may also be given to those trees which have borne heavy crops of fruit during the past season, or that show signs of deterioration in any way. These later may be gradually improved by the stimulating and protective properties of the mulch, and especially so in cases where the trees are growing in a hungry and unusually porous soil.

CLEANSING THE TREES.—The cleansing of all the trees should now be taken in hand. American blight, which is easily get-able owing to the leafless state of the trees, should be destroyed by the application of one of the many insecticides now obtainable. Where the fruit walls are built of rough material—and in some remote districts such walls are still to be found—or the surface is roughened by age, so as to form a harbour for insects, much good may be done by washing or syringing them with a weak solution of paraffin, afterwards applying a dressing of fresh lime-wash, but taking care not to injure the trees during the operation. This will, to a large extent, destroy any insects or eggs that may be secreted in the holes and crevices. In some cases, old trees growing on walls may, to some extent, be renovated by cutting back the elongated spurs to one or two buds; but this severe treatment causes the loss of a crop the following season, consequently but few trees can be so dealt with at a time. Care should be taken to gather up and burn all the prunings from old, insect-infested trees before the latter are dressed with an insecticide.

PREPARATIONS FOR PLANTING.—When the soil is in a workable condition, ground intended to be planted with fruit trees should either be trenched or dug, as circumstances may require. In gardens where the subsoil is cold or retentive, deep digging is to be preferred to trenching, nor during the latter operation too much of the subsoil is often brought near the surface, and the roots of most trees are not quick to enter such soil. Every means should be employed to encourage the roots towards the surface of the soil, for, if this is done, the trees make less strong growths, and there is a consequent increase of fruit-buds. Existing fruit borders should be examined, and if insufficiently drained, the defect should be remedied even if the border has to be renewed. During mild weather, plantations of Raspberries, Gooseberries and Currants may be made, although, for choice, the autumn is by far the better time for planting these fruits. On cold, heavy soils, planting must be deferred until February. In the meantime make every possible preparation, in order that there may be no delay, when the correct moment for planting arrives.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

SOPHRONITIS GRANDIFLORA.—The brilliant scarlet blossoms of this delightful little Orchid being now expanded they greatly brighten the cool house, and they last for more than a month. It is surprising the amount of blossom that small plants of this species produce year after year without suffering any apparent harm, and the flowers are very large in comparison with the size of the pseudo-bulbs; they are produced from the tops of these just at the time the bulb is maturing. The strain thus placed upon the roots makes it imperative that these should be well looked after, especially as regards the supply of moisture. Whilst many Orchids require much less water at this season, the *Sophronitis* needs the full supply to be maintained.

After the flowers have passed and the pseudo-bulbs have swollen to their full size, there is usually a period of inactivity when a lesser supply of water suffices, but even then it is detrimental to the well-being of the plants if the rooting material is allowed to become absolutely dry. How often

and what quantity of water is required depends entirely upon the class of rooting material employed and the size of the receptacles containing the plants.

REPOTTING.—When this is necessary it should be done soon after the flowering period, as new roots are then being produced from the partially-developed growths. Shallow pans are the best receptacles, using a size just large enough to allow about $\frac{1}{2}$ inch of compost to be placed around the roots, for these latter do not extend far as a rule, being happier clinging closely together in a sweet, open compost in a restricted area. The potting compost may consist of *Osmunda* fibre (one half), *Polypodium* fibre (one quarter), and clean, freshly-picked *Sphagnum*-moss (one quarter), the materials being chopped up and mixed together. Make provision for good drainage, and fix the roots firmly in the compost already described. Plants of this species are not difficult of cultivation when once a suitable place is found for them, and this will be not in quite the coolest house, but in one having, what I term, a good intermediate temperature. They thrive best suspended from the roof rafters, where they are well exposed to the light and where plenty of fresh air circulates.

CATLEYA.—This is the quietest time in the year for *Cattleyas*, not many species being in flower. Where hybrid *Cattleyas* and *Laelio-Cattleyas* are grown, however, some plants are nearly always in bloom. *Cattleya Percivaliana* and *C. Trianae* will be the next of the popular species to display their flowers. Already the buds of *C. Percivaliana* and early-flowering varieties of *C. Trianae* are nearly through the tops of their sheaths, and in a week or so the flowers will be in full beauty. But not only is there a scarcity of bloom at the present time, but many of the plants themselves are at rest, or nearly so. The late spring and summer blooming-species and their numerous hybrids having about completed their growths sponging and cleaning of the plants should be begun as early in the winter as possible, the first kinds to receive attention being those showing for flower. If possible, the whole stock should be treated, as there is no better or more suitable time for this operation. The house should be thoroughly cleaned down, and the plants rearranged. The atmosphere of the *Cattleya* house should not be overcharged with moisture at this

season, and, although the plants will not stand much drying at the root just now, they need less water than at any other season. Especial care is necessary with the smaller-growing roots, as these are more easily injured by drought or excess of moisture. It is always the safer plan at this season to delay watering until the following day, in cases where there is doubt as to whether or not a plant is dry. A day's drying will do no harm, but a weak plant already moist may be injured by a fresh supply of water.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

THE SEED ORDER.—There should be no further delay in making out the list of seeds required for 1911. The preparation of the list needs some consideration, and it should not be hurried over. Do not attribute too much importance to new varieties which have not been given a trial, even on a small scale.

At the same time, the improved varieties of vegetables raised in recent years should cause every gardener to try a limited number of novelties each season, so that the older varieties may be gradually discarded in favour of better sorts. It must be remembered

that there is as much labour attached to the cultivation of a bad variety as to a good one.

CARROTS IN PITS.—A bed should be prepared for sowing Carrots, if this has not been done already, so that young roots may be available as early as possible. The best way to proceed is to form a bed of leaves 4 feet deep, treading the leaves as tightly as possible, and placing over them a layer of soil to the depth of 9 inches or more. The soil may be allowed to remain loose for a few days until it has become moderately dry, when it should be spread, and beaten with the back of a wooden rake. When the surface has been made smooth, sow the seeds broadcast over the bed, and lightly cover it with finely-sifted soil. If the soil is in a sufficiently moist condition at the time of sowing, very little water will be necessary until the young plants appear, when the bed should receive a gentle application of soft water through a fine rose. From this stage, air should be freely given whenever the weather is favourable, or the plants will become drawn. Fire-heat is not necessary, provided a sufficient covering is applied to keep out frost. Slugs are often troublesome, and, in the case of neglect, they may destroy the crop. A good method of trapping them is to sprinkle the bed lightly with slaked lime, either in the early morning or late at night while the slugs are feeding. The slightest dusting is sufficient to kill any slugs which the lime reaches.

FRENCH BEANS.—A sowing of French Beans may now be made with a good prospect of getting a remunerative crop. Sow the seeds in 7-inch pots, using a compost of fibrous loam (two-thirds) and leaf mould (one-third). The pots should be crocked and filled with compost to within 2 inches of the top, and the soil made moderately firm. Seven seeds are sufficient for each pot, and the plants may be thinned to five. A top-dressing of loam should be applied when the plants are a few inches high. Place a few twigs round each pot to keep the growths from becoming entangled. An atmospheric temperature of 60° should be maintained at night, and 65° by day. The crop should be ready to gather by the end of February. Good reliable varieties of Beans for pot culture are *No. Plus Ultra*, *Osborn's Forcing*, and *Canadian*

Wonder. If a regular supply is desired, sow a certain number of pots each week through the spring months. The plants may then be thrown away directly the bulk of the crop is gathered, and there will be but little danger of red spider infesting other plants.

PUBLIC PARKS AND GARDENS.

By A. J. ALLSOP, Superintendent of Public Parks, Leeds.

HERBACEOUS PLANTS.—The value of herbaceous, flowering plants in public parks cannot be over-estimated, and, being ideal town plants, they are becoming year by year a source of greater interest and pleasure to park visitors. By carefully selecting early, mid-season, and late-blooming kinds, these old favourites yield flowers from early spring until late in autumn. There

is no other class of flowering plants which is capable of affording such a wealth of bloom, and of thriving in such adverse atmospheric conditions as herbaceous plants. In these days of heavy rates, it behoves each one to do his utmost to keep down unnecessary expenditure, whilst maintain-

ing efficiency, and herbaceous plants commend themselves to all who are anxious to make a display at little expense, for, after the first cost, a small outlay each year suffices to add new or improved varieties to the stock. The borders set apart for herbaceous plants should be sheltered from rough winds and clear of the drip of trees. The ground should be trenched, and, if the soil is heavy, some spent Hops or leaf-mould should be worked into it. In arranging the plants, no hard or fast rule can be followed, but, at least, rows may be avoided, and straight edgings in front of the border. In this matter the planter should carefully note some of the groups of plants exhibited at the leading shows.

ARRANGEMENT OF PLANTS.—The best artists in this work adopt a natural style, and arrange the plants in irregular groups. Therefore, the planter should not make a straight line along the front with some low-growing plant, or make the further mistake of placing, at regular intervals, some other contrasting species. This latter arrangement is unnatural, and I mention it in order to emphasise the fact that the herbaceous borders lend themselves to the natural style, their effect being most pleasing when formality is avoided. Take the front of a border for example. Irregular groups of *Arabis*, *Thrift*, *Aubrietia*, or *Saxifragas*, are effective, allowing the gravel to run back in the recesses. The educational side should not be neglected, but, on the contrary, where it is possible, at least one specimen of each variety of plant should be labelled, stating the botanical and common names and the Natural Order. Annuals may be planted in groups in the herbaceous borders, and they will serve to provide a display of bloom at a time when there are but few herbaceous plants in flower. If hardy flowering plants were more generally planted, in the public parks in place of the orthodox bedding, they would be greatly appreciated by the general public. Moreover, if the arrangement of the plants is a good one, it will assist visitors in making selections of suitable plants for their own gardens, thus creating a love for flowers which will never be forthcoming if visitors are shown merely tender bedding plants, which they have not the necessary means to cultivate. The uses and, I may add, abuses of public parks are numerous, but if a love for flowers can be instilled into the hearts of those who frequent these places, then it may be claimed that one useful purpose is achieved.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

FOREWORDS.—In undertaking, after an interval of many years, to write once again the weekly calendar on indoor plant-cultivation, I am encouraged by the appreciation shown by many fellow craftsmen in the past. My aim will be to assist the younger gardeners. It is not possible to write specially for every gardener each week, but I hope that my notes will appeal to all in turn.

CLEANLINESS.—In all departments of garden cultivation cleanliness is desirable, but it is not more essential to any department than the plant houses. In most establishments the present season affords one of the best opportunities for a general cleaning up prior to repotting, re-arrangement of the plants, and a general putting in order before active growth commences. The stove stands in need of this as much as any house, for it is frequently overcrowded up to the turn of the year with late-flowering subjects. Now that other and cooler houses are possibly available, let the pot plants be taken out, so

as to afford room for a thorough cleansing of the glass, the woodwork, the path and the water pipes. Meanwhile, see that the plants do not suffer by being placed in a lower temperature in another house. If, after a good cleansing of the woodwork with hot water, it is thought desirable to repaint the wood, proceed with the painting at once. If possible, I advise that every stovehouse be painted each spring, as this method is better than applying three separate coats every three or four years. After several years experience, I find that nothing beats white paint for interior use; if not white, then a pale green should be the next choice. Let the water-pipes be painted, and in doing this work look out for symptoms of a leakage, and carry out what repairs are necessary. The best preservative is black Japan varnish applied when the pipes are hot. Do not be induced on any account to use the odds and ends of paint kettles. This is done, I know, even by those who ought to know better, and injury often-times happens to tender foliage. A smooth, shining, glossy surface, such as that imparted by the Japan varnish has a good effect, and it improves the radiation given off by the pipes. Let all the brickwork be cleansed and then white-washed, using a wash made of freshly-slacked lime and just enough sulphur to be discernible.

STOVE CLIMBERS.—Care must be extended to all the permanent plants, and the present opportunity should be taken to prune, re-tie, and top-dress any plants that need such attention. Allamandas, for instance, can very well be attended to now, also any permanent plants of *Stephanotis floribunda*. The Allamanda may be pruned hard, and the *Stephanotis* only moderately, adopting, in the latter case, more of a thinning process than pruning. Climbers trained to the roof, but which have their roots in pots, should be removed, and the wires cleansed, such species, for instance, as *Dipladenia*, than which there are no prettier climbing plants grown. If there is a damp wall in the stove, I advise that it be covered with *Ficus repens* or *F. minima*, its smaller form. *Hoya carnea* and Ferns also do very well on a damp wall. A good Fern for this purpose is *Adiantum Capillus-veneris*, and it is not at all difficult to establish. The fronds are very useful for cutting, especially when they have become hard with comparative age. Once or twice in a season this *Adiantum* may be cleared of all its fronds, and any scale insects present will be destroyed at the same time.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

A GOOD START.—To obtain the best results with forced fruits it is essential that a good start be made, and the houses, trees, and all that appertain to them thoroughly cleansed in the most effective manner. The importance of this work can hardly be over-estimated, especially when the houses have to accommodate other subjects (as is the case in many establishments)

than the permanent crop, such as Tomatos, Ferns, bedding and forcing plants. These are apt to be infested with insect pests, notwithstanding that they are subjected to a careful scrutiny before they are placed in the fruit houses. The woodwork and glass should be thoroughly cleansed each

year with scrubbing brushes, using warm water, with a small quantity of soft soap dissolved in it. This will be found much more efficacious than the use of water alone, provided it is not used so strong as to injure the paint. Rinse down afterwards with clear water, applied with as much force as possible, either by means of a garden engine or hose pipe. Whether the interior of the houses are to be painted or not, they should first be well washed, and while it may not be possible to have all the houses painted each year, they should be painted as frequently as circumstances allow, as this affords the best means of destroying all insect life, and, whilst the appearance is improved, the woodwork is preserved. Though we have not used cyanide of potassium up to the present, I learn on the best authority of the excellent results to be obtained from this specific in houses badly infested with such obnoxious pests as mealy bug and scale insects. Cyanide of potassium is a most effective fumigant, but, owing to its deadly qualities, requires using with the utmost caution. Well wash all brickwork with a hot lime wash, and let the water pipes in the house be blackened. For this latter purpose I prefer to use lamp-black and oil rather than any of the paints and varnishes, which so often give off disagreeable odours when warmth is circulated in the pipes.

PRUNING.—After the houses have been cleansed, the cleaning and pruning of the fruit trees should be commenced. In the case of vines, only that portion of the bark should be removed that comes easily away without the use of a knife or scraper, excepting in cases where mealy bug has been prevalent, when rather more drastic measures may be taken. Wash the rods with a fairly strong solution of some good insecticide, taking great care not to injure the buds, and, when these have dried well, paint the rods all over with the following mixture, which I have used for a number of years, with good results. Mix together 3 pints of clay (sufficiently thin to be stirred), 1 pint of gas tar, two wine-glasses of paraffin, and a large 60-sized pot of flowers of sulphur, and boil the mixture for some time. Then add sufficient water to thin the preparation down for painting, so that it will be capable of penetrating all the crevices. For cleansing Peach trees, Figs, Cherries and fruit trees other than vines, I prefer to wash all the old wood with a stiff brush, using a strong solution of soft soap and warm water or Gishurst Compound. Scale insects are often troublesome to dislodge, and in cases where there are bad infestations of this pest on Peaches and Nectarines, it is desirable to syringe them with water heated to near the boiling point. If this is applied when the trees are quite dormant it will not do any harm. The surface soil should be allowed to dry and then be scraped up and wheeled away, together with any loose rubbish, before fresh compost is

introduced. The interior of the houses often escapes consideration, but the glass should be washed so as to admit the maximum amount of light. In houses where tanks are made to catch the rain water, it is well to see that the pipes from the gutters are first blocked in order to prevent the dirty water reach the tanks. A good supply of soft rain water is a most valuable asset in fruit culture, especially for syringing, and every care should be taken to keep the soft water supply clean.

THE FLOWER GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

RENOVATING SHRUBS AND TREES.—The present is a suitable time to examine the Laurels and other common shrubs which screen unsightly objects. Repeated surface cleanings under shrubs leave the soil exhausted, and occasional surface dressings of decayed vegetable matter become necessary for affording fresh nourishment. Do not apply less than a 6-inch thick layer of the

materials. Dead branches on old bushes should be cut out, leaving the pruning of the live shoots till the spring-time. Isolated shrubs and trees, which are seen to be getting less nourishment than they need, may also be refreshed at the present time more readily than at any other.

Some Conifers do not thrive on light soils unless they are regularly manured. A few, such as *Picea pungens* and its varieties, also *P. Nordmanniana*, *Abies Menziesii* and *Sciadopitys verticillata*, are benefited by cow manure, either laid on the surface or beneath the turf, which can be removed for the purpose and afterwards relaid. *Picea polita*, *P. nobilis*, *P. lasiocarpa*, *Pinus cembra*, *P. halepensis*, *Thuvas*, *Cupressus macrocarpa*, *C. sempervirens*, and the *Retinosporas* are examples of those that succeed on very poor soils and need not be manured. Deciduous trees often suffer from exhaustion of the soil, and I have known cases where as much as 150 loads of fresh compost have been laid over the roots of a single tree. Of Evergreen trees none responds more readily than the Holly to a heavy top-dressing of soil. Flowering shrubs which need attention in this respect include Azaleas, *Rhododendrons*, *Andromedas*, and those which in general require a moist soil. Cow manure after being stacked for 12 months and well broken exerts a wonderful influence on these plants. In the pleasure grounds the manure should be covered at once to hide what would otherwise be an eyesore, and to protect it from birds.

IRISES.—Eastern Irises which are now beginning to extend their shoots should be protected during frost, but during fine weather the covering should be removed.

CARNATIONS.—Where pheasants are troublesome Carnations will be in danger, and the only certain method of warding off the birds is to place wire netting around the beds. Then place strands of wire or rope across the beds—wire is the better—and cover all with an old herring net. Rats also are very fond of Carnations, and the frames in which plants are being wintered must be watched; if the presence of rats is suspected steps must be taken to destroy the rodents. In our case it is necessary to winter Carnations in a rat-proof house in which the plants occasionally require water at the roots. But water should be used very sparingly during winter, as excessive moisture is often the cause of failure with these plants. The atmosphere of pit or house should also be kept fairly dry.

EDITORIAL NOTICE

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens or of remarkable plants, flowers, trees, etc., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JANUARY 9—
Southampton Royal Hort. Soc. annual meeting.

FRIDAY, JANUARY 13—
Kent County Chrys. Soc. annual meeting.
Kew Gardeners' Social Evening, at Kew.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—37.9°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, January 4 (6 P.M.): Max. 41°; Min. 34°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, January 5 (10 A.M.): Bar. 30.1; Temp. 40°; Weather—Dull.

PROVINCES.—Wednesday, January 4: Max. 40° Cambridge; Min. 36° Ireland North.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Herbaceous Plants, Hardy Bulbs, Lilies, at 12, Roses and Plants at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe and Morris.

WEDNESDAY—
Perennials, Lilies and Hardy Bulbs, at 12, Roses, at 1.30; Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe and Morris.

FRIDAY—
Imported and established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe and Morris, at 12.45.

A National Botanic Garden for S. Africa.

A little more than 60 years ago a group of far-sighted men founded the Botanic Garden of Cape Town. They did more than this, for the founders formulated the policy and defined the objects of the garden. It was to serve to introduce from all parts of the globe useful, ornamental, and fruit-bearing trees, shrubs, plants, flowers, and vegetables and to promote their distribution and culture throughout Southern Africa, to afford an acclimating resting-place and dépôt for exotics; to afford facilities for the study of Botany as a science and in connection with the horticulture and agriculture of the Cape and for training practical gardeners; and to provide, for the recreation and amusement of the public and strangers, a garden with shady walks, arbours, seats, fountains, greenhouses and a display of the choicest and most delicate flowers.

Despite the sagacity displayed in the drafting of this "charter," and despite the ability and devotion of the successive directors of the Botanic Garden Ludwig Pappé, Karl Zeyher, and Peter MacOwan, the Botanic Garden has failed of its high purpose and has become merely the Municipal Gardens of Cape Town.

It has ceased to be a Botanic Garden in the true sense of the word, and now serves only the last purpose which it was destined to fulfil, offering to the citizens of Cape Town common pleasures, to walk abroad and recreate themselves.

Scarcely less pitiable, though not quite so parochial, is the state of the Natal Botanic Garden. Founded to serve purposes of State, it ekes out a paltry grant of some £1,800 a year by the sale of garden produce, from which it derives more than half its income. Waging as it does a perpetual fight against insolvency, it is remarkable that the Natal garden has been able to do anything in the direction of the scientific investigation of plants. It is as though the advancement of Genetics were entrusted by the State to an under-paid and hard-worked gardener. Scattered over S. Africa are other smaller isolated gardens, but these are all inadequately endowed and, therefore, of restricted scope and usefulness.

The one bright spot in an otherwise dismal picture is the admirable Department of Agriculture in the Transvaal, which has already done much for the farming community of S. Africa. Apart from this institution, the horticultural needs of S. Africa are unprovided for, and such work as is done is sporadic and inadequate. Let us turn for a moment from the real to—we will not say an ideal, but a reasonably proper state of affairs. S. Africa has a wonderful series of floras, some unique and all interesting. They have not as yet been fully explored. With a Botanic Garden in being, the survey of the country would proceed regularly and systematically.

The Cape Heaths, Proteas, Pelargoniums and Gladioli, which constitute the glory of the southern extremity of the sub-continent, find no place in native gardens, and are left to the European nurseryman to exploit. A Botanic Garden would bring the native plants under cultivation, improve them by hybridisation, and prepare the way for a national horticulture and a national art of landscape gardening. Notwithstanding the golden opportunity presented by a wonderful flora, notwithstanding the imperious necessity of determining the economic values of native and of introduced plants, and notwithstanding the vital importance of increasing the area under cultivation, there is at the present time no systematic investigation of the botanical resources and possibilities of S. Africa.

This is a reproach which no patriotic member of the Union will consent to endure. He knows that the future of S. Africa depends less on its mineral wealth than on its power to feed a large population, and that such power in turn depends on the scientific investigation and exploitation of the plants which grow in or may be introduced into the country. He recognises the profound truth of the oft-quoted words of Swift:—"Whoever could make two blades of Grass grow upon a spot of ground where only one grew before would deserve better of mankind and do more essential service to his country than the whole race of politicians put together." He knew, further, from the example of the home country of Kew, for instance—of Canada, of America, of Ceylon and of Java, that it is only by the State organisation and endowment of botanical science in its application to horticulture

and agriculture that Swift's aspiration can be achieved. Fortunately, the men of science in S. Africa are alive to the imperative necessity of setting their botanical house in order, and we rejoice to find that Professor H. H. W. Pearson, on the occasion of his presidential address to the Biological Section of the S. African Association for the Advancement of Science, urged upon his hearers the pressing need for the formation of a National Botanic Garden for United S. Africa.

The arguments which he used in support of his plea were put by Professor Pearson so cogently and yet with such moderation that we are convinced that they will meet with ready acceptance throughout S. Africa. These arguments we have already outlined; nor need we fill in the details, for what was remarkable prescience in 1848 is commonplace fact among the instructed of the present day.

We believe that Professor Pearson could not have chosen a more opportune time for launching his scheme. Not only has he proved its worth, but he has seized the golden hour of opportunity. Union is in the hearts of our S. African kindred, and it is now possible, by ten years of energetic and concerted action, to retrieve the misfortunes of the past and by taking advantage of the most recent advances in scientific knowledge to create an institution which shall be of untold value to the Union.

A National Botanic Garden is no luxury, but a vital necessity, and this fact must be brought home to those responsible for the Government of S. Africa. Nor do we fear that this will prove a difficult task. There is an open-mindedness and a spirit of enterprise among the men of the dominions beyond the sea, so quick to realise opportunity and so contemptuous of difficulty that the new nation will see the need for this thing and do it. Inasmuch, therefore, as it is certain that the formation of a National Botanic Garden will enhance the prosperity of S. Africa, we believe confidently that Professor Pearson's able and temperate advocacy will prevail and that a great, endowed, national institution will come into existence. It would be a splendid thing for the Union if Professor Pearson's dream could be realised and if the National Botanic Garden could take its place side by side with the new National University, and if both could find a home in the Groote Schuur Estate, under the benign shadow of the Rhodes' Memorial: the one the symbol, the other the sign and seal of a united S. Africa.

OUR ALMANAC.—We shall present with our next issue, a *Gardeners' Chronicle Almanac* for the year 1911. In order to make it as useful as possible for reference, we shall be obliged if Secretaries of Horticultural, Botanical and Allied Societies, or any of our correspondents, will send us IMMEDIATE INTIMATION of all fixtures for the year.

MR. J. E. SHILL, late Orchid grower to SAMUEL GRATRIX, Esq., has been appointed Orchid grower to Baron BRUNO SCHRÖDER, The Dell, Egham. Abundant proof of Mr. SHILL's skill was given during the time he cultivated the famous collection of the late G. W. LAW-SCHOFIELD, and since in the excellent progress made by the many rare and handsome Orchids in the collection of SAMUEL GRATRIX, Esq. Mr. SHILL is one of the newly-elected members of the Orchid Committee of the Royal Horticultural Society.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held at the Institution on January 9, at 8 p.m., when a paper will be read by Mr. E. H. BLAKE on "Notes on Highway Law as Affecting Property Owners."

THE NORTH OF ENGLAND HORTICULTURAL SOCIETY.—In respect of this newly-formed Society, which is to have its headquarters at Leeds, we are informed that the committee has appointed the Rev. J. BERNARD HALL, R.N., to the position of secretary. We congratulate the Society on the choice it has made, for Mr. HALL showed such energy and ability in promoting the fruit show and conference which took place at Hexham in October last that we are confident the important work of forming the organisation of the new Society will be in very good hands.

NEW YEAR'S HONOUR.—We are pleased to notice on the list of Honours, published on Monday last, the name of Mr. F. MANSON BAILEY, Colonial botanist, Queensland, and author of *The Flora of Queensland* and other botanical works. Mr. BAILEY is appointed a Commander in the Most Distinguished Order of St. Michael and St. George.

FLOWERS OUT OF SEASON.—In a recent issue of the *Kew Bulletin* Mr. W. J. BEAN says that although mild, the past autumn was not exceptionally so. Yet an unprecedented number of shrubs which flower normally in spring were more or less in blossom in October. These unseasonable flowers open poorly, or often get scarcely beyond the bud state. Some, like the varieties of common Lilac, have pushed many young inflorescences just beyond the protecting winter scales, and they are thus left exposed to the inclemencies of the winter. On October 21, 1910, the following shrubs were noted with fully open flowers; some, like the Laburnum, with entire inflorescences; they were all from three to seven months before their proper season:—*Berberis Gagnepainii*, *Ceanothus thyrsiflorus*, *Deutzia setchuenensis*, *Erica hybrida* and *E. lusitanica*, *Escallonia Philippiana*, *Forsythia suspensa*, *Fothergilla major*, *Genista virgata*, *Glas tonbury Thorn*, *Hamamelis arborea* and *H. Zaccariniana*, *Laburnum alpinum*, *Spirea bracteata*, *S. Thunbergii* and *S. Van Houttei*, *Syringa villosa*, *Viburnum Tinus*, *V. rhytidophyllum*, and *V. utile*.

THE IMPROVEMENT OF WHEAT.—“The Home-Grown Wheat Committee of the Incorporated Association of British Millers recommend the distribution of Burgoyne's Fife as an improvement on any known variety of English Wheat so far as quality is concerned, and as a Wheat which is likely to succeed as regards yield under many conditions, both for autumn and spring sowing.” The foregoing somewhat prescient announcement indicates the recognition of the commercial success of a great plant-breeding experiment carried out by Professor BIFFEN, of the Agricultural Department of the University of Cambridge. The dilemma in which the British farmer found himself was as follows:—A “strong” wheat produces a larger and better shaped loaf than a weak Wheat. Most high yielding British Wheats are weak in comparison with foreign Wheats. Strong Wheats from Canada, &c., are, when grown in this country, poor croppers. The problem before Professor BIFFEN was, therefore, to produce a strong Wheat of high yield. Applying Mendelian methods to Wheat—Burgoyne's Fife was raised at Cambridge, which, in the opinion of those most competent to judge, namely, the MILLERS, fulfills the conditions, and hence solves the problem. In the course of the experimental plant-breeding which led to this successful result, Professor WOOD and other workers discovered

that it is possible to confer on the white loaf the nutritive powers of the brown loaf. Thus it was found that flour acted on by a watery extract of bran—which substance is rich in phosphates and other mineral bodies—becomes of increased “strength.” As a consequence, flour is now sprayed with solutions of mineral salts similar to those contained in bran, with the result that the loaf pleases the baker and nourishes the consumer better. If Burgoyne's Fife, when generally cultivated, fulfills the expectations which it has raised—and there is every reason why it should—the Cambridge Agricultural Department will have performed a notable and brilliant piece of work.

THE BULB INDUSTRY OF THE NETHERLANDS.—In the course of an interesting article on the growth of the bulb export trade in Holland, our American contemporary *Gardening* quotes the following figures, provided by Mr. FRANK W. MALIN, American Consul in Amsterdam, which show to what gigantic proportions this trade has reached:—

		IMPORTS.	
From:—		1908.	1909.
France	Belgium		
Spain, Portugal and Greece		743,040	1,008,040
Germany and Austria		82,250	114,400
Russia		880	2,200
Scandinavia		11,220	3,960
United Kingdom		690,680	1,110,560
United States		458,240	396,440
All other countries		53,020	75,480
		EXPORTS.	
To:—		1908.	1909.
France	Belgium		
Spain, Portugal and Greece		1,654,600	2,079,220
Germany and Austria		9,194,020	10,415,700
Russia		945,340	1,142,020
Scandinavia		2,600,840	5,760,680
United Kingdom		11,062,920	14,555,360
United States		6,006,000	7,663,040
All other countries		85,580	117,400

It will be seen from these statistics that Great Britain is by far Holland's best customer for bulbs; taking nearly 40 per cent. of her total exports, and that, judging from the years 1908 and 1909, the trade, which has been carried on for upwards of 150 years, is still expanding with great rapidity.

ROAD-SIDE FRUIT TREES.—Few sights are more astonishing to the untravelled Briton than the roadside fruit trees of various German states; and though conditions would need to alter much before this delightful—and profitable—practice could be introduced into this country, there would appear to be no overwhelming reason why what has proved successful in Germany should not become a custom here. It is a striking testimony to the thriftiness of the German and to his integrity that it is possible to plant long rows of fruit trees on the public highways, and for the State to realise a handsome profit on the venture. Thus, according to an article in the *Journal* of the Department of Agriculture (Ireland) and reproduced in *Irish Gardening*, the State of Hanover alone derives a net annual profit of over £6,000 from its highway orchards. Particularly pleasing is the custom in Wurttemberg and elsewhere, whereby certain of the trees are set apart and labelled to indicate that their fruit is for general use. Many changes would have to come about before we could hope to see our country roads bordered by Apples and Cherries with their fruits intact and awaiting the gathering by a County Council official; changes both in the roads themselves, which then would be dustless, and changes in the habits of the people. But he who has observed the most reckless butcher boy pull

up his horse in a London street obedient to an uplifted hand, would not be surprised even by fugacious urbins coming to respect the inviolability of roadside fruit trees. In any case the roadside orchards of Germany cause a pleasant feeling of respect for the rural population, whose good sense and discipline render them possible.

DAHLIAS PARISIENS. Under the above name, writes Mr. W. E. Gumbleton, Messrs. Millet, the well-known Violet specialists, of Bourg-la-Reine, Seine, have this year sent out for the first time a most beautiful set of medium-sized single bicolor Dahlias, the centres of the ray petals being pure white, broadly and evenly bordered with some other colour and presenting a most novel and attractive appearance. The habit of the plants is dwarf, and the flowers look very straight in the face, the petals are also beautifully reflexed at their tips, which is quite a new feature. The *Revue Horticole*, for April 16 of this year, gave a charming coloured plate of four varieties of these pretty flowers, named, respectively, Paris, Océra, Observatoire and Tour St. Jacques. The first named is the prettiest and most distinct single Dahlia I have ever seen. The second named, when it comes true, is also most beautiful, with alternations of clear canary-yellow and the purest white, but it is, unfortunately, so apt to sport and come all yellow or all white (the only one of the set that does so) that Messrs. Millet intend to discard it.

PUBLICATIONS RECEIVED.—*The Journal of the British Gardeners' Association*, January, 1911 (Brentford: The Brentford Printing and Publishing Co., Ltd.) Price 1d.—*The Agricultural Gazette of New South Wales*, November, 1910. (Sydney: W. A. Gulluck) Price 6d.—*Congres International d'Horticulture, Bruxelles*, Vol. II. Report of the Proceedings of the Sectional Committees. (Brussels: J. Goemaere).—*Department of Agriculture, Trinidad*, Bulletin October. (Trinidad: Government Printing Office, Port of Spain)

SCOTLAND.

SIR MATTHEW G. WALLACE.

AMONG the New Year Honours announced is that of a knighthood to Mr. Matthew G. Wallace, Terregles-town, Dumfries, the President of the Scottish Chamber of Agriculture, and a well-known authority on the cultivation of Potatoes. Sir Matthew Wallace has done excellent work in connection with the Irish Board of Agriculture. He is amongst the most energetic and able of the South of Scotland agriculturists.

THE ROYAL SCOTTISH ARBORICULTURAL SOCIETY

The annual meeting of the northern branch of the Royal Scottish Arboricultural Society was held in the Council Chamber, Inverness, on December 31, under the chairman-ship of ex-Provost Gossip. A letter from Mr. Galloway, secretary of the Royal Scottish Arboricultural Society, was submitted to the effect that it was suggested that there might be a competition for the best-kept private nursery in the district in connection with the forestry department of the Highland Show in Inverness in 1911. The meeting approved of the suggestion, and a remit was made to a committee to make the necessary arrangements. Office-bearers were appointed, those including Brodie as president, ex-Provost Gossip and Mr. Scott, Darnaway, vice-presidents; and Mr. A. Fraser, schooler, Inverness, secretary and treasurer.

PLEASURE PARK FOR INSCH, ABERDEENSHIRE.

The inhabitants of Insch, Aberdeenshire, have received as a gift, from Mr. C. E. Leith-Hay, of Leith Hall, the common of the town, under the conditions that they fence it and use it for purposes of recreation. Its area is about 12½ acres.

CULTURAL MEMORANDA.

CINERARIAS.

GREATLY-IMPROVED strains of this popular florists' flower have been sent out by seed firms during recent years, whilst the "star," or stellata type marked a distinct break. The free-flowering habit and tall growth of the "stellate" Cinerarias are two of its most valuable attributes, and the inflorescences are very useful as cut blooms. For some years past we have obtained fine specimens of these plants measuring

containing the seedlings are placed in a cold frame under a north wall, where shading is not necessary, and, in consequence, the plants do not become drawn. A few days after transplanting, fresh air is admitted, and the amount of ventilation afterwards gradually increased, until the lights are removed altogether, being only replaced to ward off rain or strong winds. Under these conditions the plants grow sturdily. In about a month from the time of transplanting, the seedlings are ready for their first potting in 60-sized pots. A suitable compost is formed of loam broken up small, with

or the beginning of October the plants are ready for their final potting. At this stage the majority will require 9½-inch pots. The compost should consist of two parts loam, in a rough state, and one of leaf-soil, with some coarse sand and a little dried cow dung.

The plants are kept in cold frames as long as the weather will permit, giving plenty of air on all favourable occasions, and covering the lights with mats when frost prevails.

About the end of November or the beginning of December they are housed in a greenhouse or similar structure, from which frost can be excluded. An abundance of fresh air is admitted whenever the weather permits, and fire-heat is never used unless it is absolutely necessary. As the pots become filled with roots, liquid manure and soot water are given, with alternate waterings.

The plants are very susceptible to attacks of aphid, but this pest can easily be kept in check by fumigating occasionally. A leaf-miner sometimes attacks Cinerarias, and prompt measures should be adopted to kill the pest as soon as it appears. *Wilmot H. Yates, Rotherfield Park Gardens, Alton, Hants.*

BERBERIS SILVER BEAUTY.

This variegated variety of Berberis (see fig. 10) appeared in a batch of seedlings of *B. Thunbergii*, in America. Mr. M. J. van Leeuwen, of the Continental Nurseries, Franklin, Massachusetts, who sent us the photograph, also supplied the following particulars. The leaves have a silver variegation, the young, lateral growths being tipped with pink; but in the autumn the stems assume a light purple shade. Numerous plants have been propagated from cuttings, and the variegation has remained constant in these, so that the character may be regarded as fixed. The plant is of a compact habit of growth, and produces a large crop of coral-red berries, which provide an additional attraction in the autumn. The variety should prove a welcome addition in the shrubbery and pleasure grounds, as *B. Thunbergii* is perfectly hardy in this country, and succeeds generally in gardens.

RARE PLANTS AT BELVEDERE.

LAST summer I paid a visit to Belvedere, St. Lawrence, Isle of Wight, Lady Walsingham's interesting and beautiful garden, which is full of rare and tender plants, which Lord Walsingham has for years been collecting on the Continent and elsewhere. Much damage has been done in late winters by the frost, and four years ago 13 were registered for several days in succession (a very rare occurrence in that usually mild locality), this creating havoc among the plants. One of the most serious losses was that of a splendid specimen of the very rare *Lagunaria Patersonii*, from Norfolk Island, which was 6 feet in height and as much in diameter, and was covered with flowers every summer. This plant is very rarely met with in English gardens, and I believe it is not in commerce. The Bouvardias, of which there are a dozen plants, the sorts grown being *B. triphylla* (with scarlet flowers) and *B. Alfred Neuner* (with white blossoms), were badly cut, and, though alive, were much smaller than they were five years ago. The *Echiums* also were killed, as was a fine bush of *Sparmannia africana*, 10 feet in height. However, in spite of these losses, there are still a large number of rare and interesting plants in the garden. The handsome *Salvia dichroa*, introduced by Lord Walsingham from the Atlas Mountains in North Africa, was commencing to perfect its tall, purple-blue and white flower-spikes. It is a splendid plant, and, when in full bloom, is the glory of the garden. It dies down early in the autumn, and throws up new growth in October. This is sometimes injured by the frost, but the

FIG. 10.—BERBERIS THUNBERGII "SILVER BEAUTY."

3 feet in height, and as much through. These never fail to attract attention by their beauty, and are in great demand for embellishing dwelling rooms, where the plants remain in a good condition for one or even two months.

The seeds are sown in pans about the first week in May, a light compost being employed. They germinate readily in a greenhouse temperature. When the seedlings appear they are exposed to the light, but shade is provided from bright sunshine. In the course of a few weeks, the seedlings are pricked out into boxes at a distance of 2 inches or 3 inches apart. The boxes

a liberal addition of leaf-mould and sand. Return the plants to the frames, and follow the same conditions as to ventilating advised above. Attend to the watering of the plants with care, and, on very bright days, give a light spraying overhead.

Afford the plants larger pots as required, and for the second shift use 6-inch pots, and a similar compost as before, but in a coarser condition. As the autumn advances, our plants are placed in a cold frame facing south, and fully exposed, the sun at that time of year rarely being too strong for them. About the end of September

Supplement to the "Gardeners' Chronicle," Jan. 7, 1911.

BRASSO-CATTLEYA DIGBYANO-MOSSIE, "WESTONBERT VARIETY."

A Hybrid from *Brassavola Digbyana* and *Cattleya Mossie*. (See page 4.)

IN THE COLLECTION OF LIEUT.-COL. SIR GEORGE HOLFORD, K.C.V.O.

plants are never killed in South Devon, though entirely unprotected. *Fuchsia boliviana hybrida*, with clusters of long, drooping, crimson flowers, was an exceedingly pretty plant, and one seldom cultivated out-of-doors in English gardens. Large shrubs of the South African *Bowkeria Gerardiana*, formerly *B. triphylla*, were setting their buds. These were many feet in height, and had not been injured by the frost; it is apparently a fairly hardy subject. The leaves are sometimes browned in the winter, but no further damage occurs. *Cantua dependens*, from the Peruvian Andes, grown against a wall, flowers fairly well. This plant is to be found in a few Cornish gardens, but it appears not to bloom very freely.

Dianella nemorosa is a pretty plant, throwing up flower-spikes over 2 feet in height, and bearing lavender-blue blossoms. A group of seven fine bushes of *Citrus trifoliata* should make a fine show if they bloom well. Great clumps of *Agapanthus umbellatus* were in splendid health, and were throwing up numerous flower-spikes. *Panacratium illyricum* was evidently quite at home, as it flowers very freely, and is surrounded by numbers of self-sown seedlings. *Cyclamen latifolium*, which is generally treated as a greenhouse plant, flourishes at Beldere on a sloping bank in the open, and as many as 200 flowers have been borne by a single corm, while *Ixias*, *Freeseias*, *Babianias*, *Sparaxis*, and *Tritonias* thrive to perfection. *Cassia floribunda* appeared very similar to *C. eorymbosa*, so largely grown in Devon and Cornwall against open walls, but it flowers earlier. The Mexican *Fendlera rupicola* was covered with countless narrow-petalled, white blossoms, about an inch across, and was a very attractive sight; it seeds here freely, while another pretty shrub which was perfecting bright-yellow flowers was *Cytisus elongatus*. *Drimys Winteri*, 8 feet in height, had passed out of bloom; but *Sophora flavescens* was bearing clusters of yellow blossoms, and *Purshia* (*Onosmodium*) *tridentata* had its stems studded with pale-yellow flowers. In a pond in front of the house, in which the best of Marliac's Water Lilies are grown, was *Thalia dealbata* and *Crinum aquaticum*, which bears pink flowers. *Edwardia* (*Sophora*) *microphylla*, 8 feet in height, was said not to flower freely, but with me, in South Devon, it is a sheet of bloom every year. *Lavatera maritima bicolor*, common in the south-west, where it is often grown as *L. assurgentiflora*, was doing well, and *Rekmania angulata*, which remains out all the winter, was in full flower and very healthy.

There is a fine collection of climbers at Beldere. A curious creeper was *Ephedra altissima*, from Northern Africa. This is a prodigiously rampant grower, and had entirely smothered, with a tangled maze of slender shoots, a broken-down tree to a height of 8 feet. Several plants of *Clematis tangutica* were grown. One large specimen has never flowered, and this spring, when I was at Burncoose, in Cornwall, Mr. P. W. Rogers showed me a very large plant which had never bloomed, so that there is evidently a shy-flowering form of this *Clematis*. Other plants at Beldere, however, which were raised from imported seed, have flowered freely. *Stamtonia latifolia* had grown into an impenetrable thicket over some rockwork, and *Muehlenbeckia complexa* had clambered up a tree in a tangle of twining shoots to a height of 20 feet. *Salpichroa rhomboides*, a native of Buenos Ayres, was a pretty climber, studded with numberless small, white flowers, and *Polygonum baldschuanicum* had rambled for a long distance along the top of a pergola, and created a charming picture, with its numerous drooping, flesh-pink flower-clusters. The Himalayan *Thladiantha dubia*, which is very effective, with its brightly-coloured fruit, was doing well, and *Vitis Thunbergii*, which assumes such gorgeous colouring in the autumn, was growing strongly, as was *Akebia quinata*. *Bignonia Tweediana* was clambering over a summer-house, and *Actinidia chinensis* had made shoots

over 15 feet in length; but one of the prettiest climbers was *Actinidia arguta*, which had grown to the eaves of the house, and was covered with countless clusters of white flowers with black-tipped stamens. Other creepers were *Mandevilla suaveolens*, *Clematis Nellie Moser* and *The Gem* (blue), *Jasminum primulinum* and *Ampelopsis sempervirens*, which, for some unknown reason, died completely down last year, and is now about 7 feet in height. A very fine plant of the New Zealand *Solanum aviculare*, about 10 feet in height, and many feet through, was growing in front of a summer-house, and was bearing its violet, golden-centred blossoms in abundance. This is a tender plant, and has been killed several times in South Devon. *Mesembryanthemums* provided a glorious colour-picture, and there was an admirable collection of succulents growing in the crannies and fissures of the natural rock, which here and there crops out in the garden. Among these were noted *Agave Victoria Regina*, *Cereus peruvianus*, *C. flagelliformis*, *Echinopsis Zuccariniana*, *E. Eyriesii*, *Opuntia glauca*, *O. Salmiana*, *O. arborescens*, *O. Rafinesqui*, *O. humilis*, *Mammillaria centricirra*, *M. missouriensis*, *Gasteria verrucosa*, and numbers of other plants of the same section, many of which were in bloom. *Wyndham Fitzherbert*.

AMERICAN NOTES.

THE WHITE MEDAL OF HONOUR.

As important event in American horticulture during the past year was the establishment of the George Robert White Medal of Honour to be awarded by the Massachusetts Horticultural Society through its executive.

Mr. George Robert White, of Boston, in his deed of trust accompanying the fund, stated that

FIG. 11.—THE "WHITE" MEDAL.

he thought some suitable recognition should be made of those persons who have accomplished important work in horticulture; the award to be made independently of, or in addition to, any prizes or certificates of merit that may be bestowed by the Massachusetts Society in the course of its regular duties.

He, therefore, founded the George Robert White Medal of Honour Fund, the income of which is to be devoted annually for the specific purpose of providing a gold medal, to be awarded to the man or woman, commercial firm, or institution that has done the most during the year, or in recent years, to advance the interest in horticulture in its broadest sense.

While the medal is intended principally to recognize work accomplished by a resident of the United States, it may be awarded also to a person, commercial firm, or institution of some other country, the results of whose work in horticulture may be of direct benefit to the interests of horticulture in the United States.

The medal was struck at the United States Mint in Philadelphia, from 24 carat gold. It is 2½ inches in diameter, 5-32nds of an inch thick, and weighs between seven and eight ounces. It

was executed by Mr. John Flanagan, a native of Newark, N.J.

The first award of the medal has just been made to Prof. Charles S. Sargent, Director of the Arnold Arboretum, and very well known to readers of the *Gardeners' Chronicle*, whose eminent service in horticulture is generally recognised both in the United States and abroad. His great work has included the introduction of many ornamental trees and shrubs into New England, and experiments for testing their hardiness. *W. P. Rich, Secretary, Massachusetts Horticultural Society.*

TREES AND SHRUBS.

SPECIMENS AT ARLEY.

A SPECIMEN of *Thuja occidentalis*, which was blown down in the Arboretum here last month, was 42 feet 7 inches in height, 4 feet 1 inch in girth at the base, and 3 feet 2 inches at 5 feet from the ground. The age of the tree, counting the rings at the base as near as could be ascertained, was 75 years. The centre of the trunk was rotten for 5 feet up.

The largest specimen of *Thuja occidentalis* catalogued* is 45 feet high and 7 feet 6 inches in girth near the ground, where it divides into three stems. The soil here is a stiffish loam. Two self-sown seedlings have been found, one growing under the limbs of a tree of *Carpinus caroliniana*† which are lying on the ground has thus been protected from the mower's scythe, and the other on the top of a brick garden wall from where it has been removed and planted in the nursery. These two seedlings are growing extremely slowly, and though now six and four years old respectively are only 6 inches and 4 inches high.‡

A tree of *Juniperus virginiana* which has been lying in the last three years and has just been cut down, gives the following dimensions: Height 54 feet; girth at base 4 feet ½ inches; girth at 5 feet 3 feet 11 inches; girth at 27 feet 2 feet ½ inch. The age of the tree by counting the annual rings was as near as could be ascertained 75 years. This tree was growing on light loam, and was fastigate in habit. It also had three complete twists in the trunk from the base to the top, which turned the opposite way to the hands of a watch, namely, opposite to the sun. This tree furnishes the ordinary pencil Cedar of commerce.

The largest *Juniperus virginiana* growing here§ is 70 feet high and 4 feet 10 inches in girth at 5 feet. The highest price paid for the timber of this tree by pencil makers is, I understand, between 6s. and 10s. per cubic foot. Those who are thinking of planting it for profit may be interested in these dimensions and the yields the trees have taken to grow. *Robert W. Bailey, Junr., Arley Castle, Buntingford.*

* *Horticulturist*, Nov. 341, p. 12; Nov. 342, p. 102; § No. 4.

NURSERY NOTES.

A NEW SEED ESTABLISHMENT.

THE business of Messrs. James Carter & Co., nurserymen and seedsmen, has been conducted at Holborn since it was founded by the late Mr. James Carter in 1836. But with 1911 the firm commenced a new era, for its headquarters have been transferred to Raynes Park, a suburb close to Wimbledon, although premises at High Holborn and Queen Victoria Street, City, will still be retained.

Several disadvantages existed in having the main establishment in the Metropolis, the principal difficulty being that of obtaining sufficient space for extending the premises. Moreover, the trial grounds (so important an adjunct in conducting a business of this nature) were, if necessary, detached from the central organisation. The firm, therefore, decided to build a new warehouse, with accommodation for all the various branches of a great seed and nursery business.

A site of about 25 acres was selected at Raynes Park, and a start made in September last to

The building is heated by one mile of 4-inch hot-water pipes, 48 radiators, and a boiler with a capacity of 1,250,000 British thermal units has been installed.

It is lighted by electricity, and the same power is employed for driving the machinery used in seed cleansing and other purposes, for which installation $8\frac{1}{2}$ miles of insulated cable were necessary to conduct the energy of 300,000 candle power.

The main entrance to the building is reached from the road by a circular gravel drive and two flights of Portland stone steps, ornamented on either side by marble lions, 7 feet 6 inches high, that weigh 25 cwt. each. The portico, supported by four Portland stone columns, 14 feet high and 6 feet in circumference, is decorated with the Royal Arms, wrought in copper.

The private and general offices occupy a considerable space, and the seed and bulb warehouse is reached by passing through a pair of folding doors, the clerical and executive departments being quite separate. Our first impression on entering the seed stores was that we were in a

what look like Wardian cases. Warmth and other conditions suitable for germination are provided, and the germinating capacity of the various stocks ascertained. The main stock of seeds is stored in the spacious basement. It was no light task to transfer the countless heavy sacks, with the thousand-and-one other things, from Holborn to Raynes Park, nevertheless the work was accomplished in the short space of one week. During the coming season, the grounds will be planted with trial plots of the various plants, so that the large grounds originally devoted to this purpose at Mortlake will be no longer needed.

The necessities of the large staff have been studied in every respect, and suitable accommodation provided.

The best season of the year to pay a visit to Raynes Park will be that extending from June to September, as the various trials may be expected to be in progress at that time.

ODONTOGLOSSUM CERES MAGNIFICUM.

THIS beautiful hybrid is the result of a cross between *Odontoglossum Rossii rubescens* and *O. Rolfeae*, and it is the finest variety of this cross yet shown. The large flowers have handsome, claret-red markings, the tips of the petals being tinged with rose, and this colour is also present in the labellum. On December 20, the Orchid Committee of the Royal Horticultural Society awarded the plant a First-class Certificate when it was shown by Messrs. Charlesworth & Co., Haywards Heath.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

IMPROVING SOIL OF ALLOTMENT GARDENS.—

There is still room for much improvement in the cultivation and general management of allotments. In many cases it is the custom, after one crop is secured during the summer, to leave much of the ground not only uncropped, but uncultivated until the following spring. Not much can be done now in the way of planting vegetables, but there should be no delay while the weather remains open to clear the different sites of decaying refuse, applying manure, and turning the ground over in order that frosts may sweeten and pulverise it. Many have to contend with soil of an unfavourable nature, and to dress such land heavily with crude manure is not always the best means of improving its staple. The value of all manures is practically lost upon land that is sour and waterlogged during most of the winter months. Moisture in the ground is necessary to sustain crops, and air in the soil is equally necessary. The best land or site is not always available for allotment or vegetable gardens, and to bring the ground into a thoroughly fertile state much labour and expense are often necessary. Land which is naturally heavy and retentive requires to be worked while in a suitable condition, that is, when the surface is dry. Moreover, while it is always best to perform the work neatly, too much time is frequently spent in trying to break rough clods down to a friable state. This is wrong, as the first heavy rain would cause such broken soil to run together and form a solid mass long before the time for sowing or planting arrives. The rougher heavy ground is turned over and left through the winter the better. Very stiff land should be dressed, for the first season or two, with burnt garden refuse, road grit, fine ashes, old mortar, and especially lime. As these materials become incorporated with the land the texture will improve, and then it may be enriched. The ridging of heavy land is of great value, especially ground intended to be planted with Potatoes. If the ridges are made 2 feet broad at the base, the Potato sets may be planted between. The ridge is then forked down, and the ground remains light and porous over the sets. *R. P.*

FIG. 12.—ODONTOGLOSSUM CERES MAGNIFICUM: SEPALS AND PETALS BLOTCHED WITH CLARET-RED.

prepare it for forming nursery and trial grounds. The whole of the land was trenched, this item alone involving an expenditure of £1,000.

A week or so ago, when we visited the new establishment, the building to be utilised as seed stores, offices, &c., was practically complete. It does not in the least resemble the orthodox factory or seed warehouse, but, on the contrary, an imposing building, that may be likened somewhat to a large orangery. It is built on a raised terrace, and forms a conspicuous object to travellers on the main line of the London and South Western Railway, which forms one of the boundaries of the nursery. Messrs. Carter have supplied us with many interesting particulars, of which we give the following:—The main building is 320 feet long and 110 feet wide, with a basement 180 feet by 110 feet, and it covers a little over two acres. Six hundred tons of English steel and 400 tons of asphalt were used in constructing the roof and floor. For glazing purposes, 12,000 superficial feet of glass were required in all a little over a quarter of an acre,

gigantic granary, sacks upon sacks of grain being piled almost to the roof in long rows.

The various processes of cleaning, sorting, and packing the seeds were most interesting. The seeds are cleaned in electrically-worked machines, designed by members of the firm. The machine not only removes dust and other foreign matter, but separates the light seeds, sifts out the small ones, and delivers the plump, polished seeds into sacks. But this is not all; after leaving the machine, the seeds are taken to another department for further sorting. They are dropped through hoppers on to an endless band, driven by a three-speed gear, under the inspection of an assistant, who picks out all mildewed and otherwise defective specimens, the perfect samples remaining on the band, to ultimately fall into a sack. As each sack is filled, it is taken to the packing department, where the seeds are packed ready for distribution.

The testing of the various seeds is undertaken in a special department, where specified numbers are placed between damp felt, and placed in

THE PERPETUAL-FLOWERING CARNATION.—It was regrettable to notice the paucity of exhibits displayed by amateurs at the recent show of the Perpetual Flowering Carnation Society. This type of Carnation is essentially an amateur's flower, for, with only a slightly-heated greenhouse, a beautiful display may be obtained. In the classes open only to amateurs and gardeners, many valuable prizes, including the President's (Lord Howard de Walden) 50-guinea Challenge Cup, are offered. Those intending to exhibit at the forthcoming show, to be held in the Royal Botanic Gardens, should become members at once. *Laurence J. Cook, Hon. Treasurer, Wellington Road, Bush Hill Park.*

BANANA CULTURE IN ENGLAND (see vol. xlviii., p. 464).—I can endorse fully all that Mr. Ely has said with respect to the superior flavour and size of the home-grown Banana. Musas are very ornamental subjects in the Palm house, and they also form a suitable background in the large plant stove, where they may be fruited successfully. I enclose a small photograph [Not reproduced—Eus.] of a Banana in fruit. The stem was 5 feet high, the largest leaf being 5 feet long and 2 feet 8 inches wide. The bunch of fruits weighed 52 lbs., and it had about 150 "fingers." Musas enjoy heat, moisture, and plenty of manure during the growing season, but they do not suffer materially if the temperature falls as low as 40°. One noticeable feature of the home-grown Banana is its thin skin compared with the skins of imported fruits. *W. Phillips, Derry Ormond Park Gardens, Cardiganshire.*

IRIS HISTRIOIDES.—Enclosed is a flower of *Iris histrioides*. The first bloom opened a week ago, and now in a south border there is a group of a dozen flowers expanded. Could anything be more beautiful or satisfying at the end of December?—not in the favoured south, but in the Thames Valley district. The general colour is that called marine blue (p. 211 of the *Repertoire de Couleurs*), but with some red in it, and the beauty is much enhanced by the white and yellow markings in the throat and on the fall. The scent, too, is delicious. Here the plant is perfectly hardy and a true perennial, needing no sort of care or attention, whereas I have found *I. histrio* quite unmanageable. *A. C. Bartholomew, Park House, Reading, December 27.*

POISONOUS SHRUBS.—In the issue for December 24 (page 480) *Doubtful* writes: "Yew is undoubtedly poisonous, but its effects are remarkably variable, and seem only to be shown when the animal takes it on an empty stomach." I may instance a case where an old Yew tree was cut down and the branches deposited in the corner of a field, where several yearling calves were grazing. This was on a Saturday afternoon, and, strange to say, some of the calves were found dead on the Sunday morning following, as many as six dying. I have also known a case of a man being overtaken by violent vomiting after chewing Yew branches, and in the space of a few hours he expired. Both these cases prove how dangerous it is to have Yew branches in reach of live stock or persons who do not understand their poisonous nature. *J. Flanagan, Carrigart, Co. Downal.*

AMERICAN GOOSEBERRY-MILDEW.—During December this pest made a rapid development. Quarters of Gooseberry bushes that I inspected at the end of November and found free from the disease were, by the middle of December, badly affected. For three months we have employed three "trimmers," or pruners, and before these commenced work another person and myself went over the bushes in order that the trimmers should not be delayed. When any considerable amount of the disease was discovered the fact was reported to me, and more than once this was done. But it is satisfactory to know that in places where the disease was very bad in 1909, it has not been seen during 1910. Keepsake is by far the most susceptible variety to take the disease, but this week I have discovered a large plantation of Whinham's Industry affected. Amongst many acres of Gooseberries I found one row of an unnamed sort free from disease, although rows on either side were affected. According to the official notice, all bushes should be trimmed by December 18. *Stephen Castle, Walpole St. Andrew's, Wisbech.*

THE CRAB APPLE.—The different varieties of ornamental Crab Apples are often overlooked by those who are interested in trees and shrubs. A few standard trees, or even spreading bushes of the various varieties may, with advantage, be included in the mixed shrubbery or plantation, as they give colour and brightness in spring, while in flower, and again in late summer and autumn, when the branches are clothed with highly-coloured fruits. Some of the most showy fruiting sorts (especially such varieties as the Dartmouth and John Downie) are highly decorative in autumn, and are to be recommended for their fruiting alone. Still, there is a further claim for the Crab Apple, as very few of the better known dessert or culinary Apples make so good a preserve as these. Indeed, jelly made from Crab Apples—even from those which are considered coarse and worthless, such as grow in the hedge-rows—may be made into the most delicious jelly. If a few trees of Crab Apples are included during the present planting season, they will give pleasure in more ways than one. As a rule, owing to their naturally hardy habit, the Crab will produce a full crop of fruits where choicer kinds fail. *R. P.*

PLANT NAMES IN PUBLIC PARKS. During a visit to the Botanical Garden in a well-known London park a short time ago I was impressed by the confusion which existed in the nomenclature of some of the Saxifrages. A variety of *Saxifraga muscoides* was labelled *S. decipiens*. It is not difficult to distinguish these two plants, as *S. decipiens* is very hirsute and a more compact-growing plant than *S. muscoides*. Another *muscoides* variety appeared under the name of *S. oppositifolia*. *S. rotundifolia* was labelled *S. peltata*, and *S. sancta*, a spiny-leaved, bright-yellow-flowered species, figured as *S. hypnoides*, which is a white-flowered, mossy Saxifrage. I also saw two plants labelled *Saxifraga longifolia*, which looked like *S. Cotyledon*, and was certainly not *S. longifolia*. Attention needs to be drawn to such errors as these, as botanical gardens are places where some visitors study the nomenclature of plants. *E. E. Ward.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 3.—The first meeting of the year 1911 was held on Tuesday last, in the Society's Hall, Westminster. The show was a small one, but there were several exhibits of importance, notably a magnificent display of *Cypripediums* shown by Messrs. ARMSTRONG & BROWN, for which a Gold Medal was awarded; a collection of Grapes from the Earl of HAREINGTON's garden; Apples shown by Messrs. JOHN PEED & SONS; and some exceptionally large Onions exhibited by MRS. DENISON, Little Gaddesden. The exhibits of Orchids were as interesting as ever, for, besides the collection of *Cypripediums* referred to, there were other good groups, and many new plants.

The ORCHID COMMITTEE granted two Awards of Merit to *Odontioda Cocksonae* and *Laelo-Cattleya Cranstoniae* "Westonbut variety."

The FRUIT AND VEGETABLE section was represented by several exhibits, but no Award was made by this Committee to a novelty.

The exhibits before the FLORAL COMMITTEE were fewer than usual, and only one Award of Merit was conferred by this Committee, namely, one to a crested *Cyclamen*.

Floral Committee.

Present: H. B. May, Esq. (in the Chair); and Messrs. John Green, R. C. Notcutt, W. J. Bean, G. Renthe, W. Howe, C. R. Fielder, C. Bick, J. Jennings, J. F. McLeod, H. J. Cuthbush, Arthur Turner, Chas. Dixon, R. Hooper Pearson, Chas. E. Shea, J. T. Bennett Poe, Chas. E. Pearson, W. P. Thomson, E. H. Jenkins, F. Page Roberts. (Rev.) W. J. James, George Paul, H. J. Jones, W. B. Cranfield, R. W. Wallace, and A. Kingsmill.

Messrs. JAMES VITCH & SONS, LTD., King's Road, Chelsea, staged miscellaneous flowering plants, chiefly of greenhouse species. They showed batches of winter-flowering Begonias, *Azalea indica*, *Gesnera Ajacina* (with beautiful, reddish-orange flowers and richly-coloured leaves), *Luculia gratissima*, and Orange trees in fruit. A

pretty combination was made with *Moschosma riparium* and rose-coloured Begonias. Interesting plants were observed in *Canarina Campanula* and *Eubibia officinalis*. The latter is a dwarf, tender species, newly introduced from China. The inflorescences are characteristic of the genus, having pale blue flowers with an orange-coloured "eye." (Silver Banksian Medal.)

Messrs. W. CURTIS & SONS, Highgate, showed indoor plants, a selection of Alpines and varieties of the perpetual-flowering type of Carnation. Well-grown Palms, Ferns, *Dracenas*, *Daphnes*, and ornamental Oranges were freely displayed. The Alpines included bright batches of Irises, including *I. histrioides* major, *I. alata*, *I. Bakeriana*, and *I. reticulata* var. *Kreblager*. The Carnations formed a showy group, most of the popular sorts being represented, as well as many novelties. These latter included *Scarlet Glow*, superior, by comparison, to *Britannia*; *Countess of Bradford*, a yellow-ground fancy; *Miss Winnie Prior*, white, with scarlet markings; *Lady Elphinstone*, pink; *White City*, white, with well-shaped and stout petals; and *Mrs. Fortescue*, a bright flower of rose tint. (Silver Flora Medal.)

Messrs. STUART LOW & CO., Bush Hill Park, Enfield, exhibited *Cyclamens* and Carnations. The latter included such newer varieties as *Lady Alington* (salmon pink), *May Day* (salmon rose), *White Perfection*, and *Princess Juliana* (orange-red).

Messrs. W. WELLS & CO., LTD., Merstham, exhibited a vase of the fine white Carnation *White House*, which recently received an Award of Merit from the Floral Committee, the blooms appearing finer than on the previous occasion.

Rev. H. BECKFORD, Etwell, Derby, staged a large exhibit of *Cyclamens*, having them in batches of white and pink varieties, with a few of deeper colour at one end of the group. Some were of the crested type, with distorted petals, the flowers being not unattractive. (Silver Flora Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, filled a large table with Ferns in great variety, all of a decorative type, many showing handsomely-tessellated fronds. One of the most beautiful varieties was *Pteris cretica* (Childs), with finely-fimbriated fronds, and as robust as the type. *Adiantum Fergussonii* is a noble looking species, the fronds having a bloom-like sheen. In *Nephrolepis superbissima* the foliage is rested in all directions; but the gem of the collection was *Davallia tenuifolia* Veitchii. At intervals in the group were specimens of *Platycoriums*. (Silver Banksian Medal.)

Messrs. THOMAS ROCHFORD & SONS, Brookbourne, staged a batch of *Begonia amabilis*, of the *Glorie de Lorraine* type, with large inflorescences of pink flowers, said to be of stouter texture than those of the ordinary variety. This quality makes the sort especially suitable for market purposes. At either end of the group were fine specimens of Ferns, in the one case of *Nephrolepis lycopodioides*, and the other of *Cyatium falcatum* Rochfordii. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, displayed bunches of *Zonal Pelargoniums*. The largest flowers were of the variety *Sir Thomas Hanbury*, the colour being crimson. Others of special merit were *Hibernia* (red), *Helen*, *Countess of Radford* (rosy-cerise), *Jupiter* (scarlet), *Lucania* (rose, flushed with orange), and *Saxonia*.

Mr. L. R. RUSSELL, Richmond, Surrey, showed Ivies, varieties of *Elaeagnus*, *Osmanthus purpureus*, *Garrya elliptica*, golden and silver-leaved Box, and *Cupressus macrocarpa* Hitchc., as small specimens in pots. There were also many pretty ferned plants of *Aucuba*, in small receptacles. The Ivies were shown in great variety, being principally golden-leaved sorts.

Messrs. W. PAUL & SONS, Waltham Cross, showed *Camellias*, both as cut blooms and pot plants. It was a representative collection, embracing such well-known varieties as *Marchioness of Exeter* (rose), *Mme. Ambrose Verschaffelt* (of beautiful form and light rose in colour), *Mercury*, *Lady McKimion* red, splashed with white), tricolor (white, rose, and red), *Mars* (a single variety of reddish-rose colour), *fimbriata* and *alba plena* (both old, but good, white varieties).

The GUILDFORD HARRY PLANT NURSERY exhibited varieties of shrubby *Veronicas*, including *V. Hectori*, *V. cupressoides*, *V. epacridea*, *V. decumbens*, and *V. pinguifolia*. The small-leaved *fidera* *Ilex minima* was observed, also *Abnans*

amurensis, *Arenaria balearica*, and *Morisea hypogrea*.

Mr. G. REUTHE, Keston, Kent, showed a few early-blooming hardy plants and Alpines, such as *Iris reticulata*, *Parochetus communis*, *Cyclamen Atkinsii purpureum*, *Leucojum carpathium*, *Hamamelis Zuccarini*, *Helleborus levidis*, and *H. fetidus*. The American Partridge-berry, *Mitchella repens*, was shown in fruit: the berries resemble hips of the Hawthorn.

The Misses HOPKINS, Mere Gardens, Shepperton, staged a small exhibit of Alpines, which included some well-flowered plants of blue Primroses.

AWARD OF MERIT.

Cyclamen.—An Award of Merit was made to a strain of *Cyclamen* in which the papilio form of the flowers was shown at its best. The spreading, butterfly-like flowers were exceedingly large, and the colour was purplish-rose, with deeper colour in the centre. Shown by the Rev. H. BUCKSTON.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), de B. Crawshaw, R. G. Thwaites, H. Little, W. Cobb, F. M. Ogilvie, F. J. Hanbury, H. G. Alexander, A. Dye, J. Cypher, Stuart Low, C. H. Curtis, Gurney Wilson, W. H. White, J. Wilson Potter, and W. H. Hatcher.

There was a great show of *Cypripediums*, the magnificent group staged by Messrs. ARMSTRONG & BROWN, of Tmbridge Wells, extending the entire length of the end staging in the hall, and for which the Committee awarded the Gold Medal, being equal to the best ever staged. The group contained over 500 finely-grown plants, including nearly 200 species and varieties, the leading forms of *C. insigne* and others being massed several together. Prominent were such varieties of *C. insigne* as Monarch, Memoria Queen Victoria, James Renwick, Harefield Hall, Aberdeen, and Pittianum, which is by far the best of the Beckmannii class. In a selection of yellow forms of *C. insigne* there was a good batch of *C. insigne Sandera*, still the best yellow variety. Others noted were *C. Niobe Westonbirt* variety, *C. Beckmannii* (a truly noble example with a very massive flower), *C. Cowleyanum*, *C. Goliath* (a superb and distinct hybrid), *C. Leonitis* (with a broad expanse of clear white in the dorsal sepal), *C. Charlesianum* var. Minnie, *C. Sultan*, *C. Mrs. Spender* (Clay, and *C. Captain Spender* Clay, two very pretty Fairrieanum hybrids, both with light-yellow ground colour; and, among other new hybrids, a very fine cross between *C. Lathamianum* and *C. Euryades*, a grand flower, the nearly black basal markings of the dorsal sepal contrasting well with the clear-white upper half.

R. G. THWAITES, Esq., Chessington, Christchurch Road, Streatham (gr. Mr. J. M. Black), showed a group which came next in importance, and was adjudged the Silver-gilt Flora Medal for a most attractive group, the prevailing feature in which was a large number of plants of his white-petalled strain of *Cattleya Maggie Raphael*, and which have been admired at most of the meetings during the winter. The different forms varied in the depth of colour in the rosy-crimson labellum and in the gold veining, but all are charming flowers, and specially desirable at this season. With them were a selection of scarlet and deep-red *Cochliodas* raised at Chessington, several forms of *Sophro-Cattleya Saxa* and other *Sophro-Cattleyas*, a fine form of *Sophranitis grandiflora*, and other showy Orchids.

MESSRS. J. CYPHER & SON, Cheltenham, were awarded a Silver Flora Medal for a select group, principally of *Cypripediums*, among those noted being *C. Beckmannii* (with very broad petals), *C. Charlesianum* Cypher's variety (a large, yellow flower of good shape), *C. Euryades Burford* variety (with purple spots on the white dorsal sepal, contrasting with *C. Euryades splendens*, which has the lower half of the dorsal sepal claret colour); varieties of *C. aureum* (of which *C. a. Marie* was one of the best), good forms of *C. insigne* and *C. Lceanum*, and many unnamed seedlings, of which the finely-coloured hybrid between *C. Mons de Carte* and *C. Thompsonii*, that between *C. Euryades* and *Mrs. Wm. Mostyn*, and the one between *C. Lceanum* and *C. Swinburnei* were remarkably good. At the ends were good selections of *Masdevallias*, *Calanthes*, and *Lycastes*.

MESSRS. STUART LOW & CO., Bush Hill Park, Enfield, were awarded a Silver Flora Medal for a pretty group containing a great variety of species. At the back were some good *Laelia autumnalis*, a selection of coloured and white forms of *Laelia anceps*, the *L. anceps alba* Worthington's variety being the best white, with no other colour than the tinge of lemon-yellow in the lip; *Oncidium varicosum Rogersii* (with very large, yellow flowers), *O. bicallosum*, a selection of fine forms of *Cattleya labiata*, and a remarkably handsome *C. Octave Doin*, some good hybrid *Cypripediums*, including *C. Curtmannii*, *C. Niobe*, *C. Euryades splendens*, *C. Priam*, *Odontiodas*, *Odontoglossums*, *Bulbophyllum sicybulbon* (with racemes of orange flowers), *Pleurothallis pulchella*, and *Renanthera Imshoottiana*.

MESSRS. JAMES VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Banksian Medal for a representative group of *Cypripediums*, of which the best were their new *C. Clonia* (a large, finely-formed, and prettily-marked flower), *C. Ville de Paris*, many good varieties of *C. Euryades*, *C. Elatior*, varieties of *C. aureum*, and *C. insigne*.

MESSRS. CHARLESWORTH & CO., Haywards Heath, staged a small group of specially good things, which included *Laelio-Cattleya Bella alba* (*L. purpurata alba* × *C. Warneri alba*), a handsome flower with pure-white sepals and petals and rich, purplish-crimson lip; *Odontoglossum Aireworth* (*Lambeauium* × *crispum* Aleyon), a model flower, heavily blotched with claret colour; two white-petalled *Cattleya Maggie Raphael*, *Odontoglossum crispum* Nauthotes, a good scarlet *Odontioda Bradshawia*, and the original *Cypripedium Priam*.

Lieut. Col. Sir GEORGE L. HOLLORD, K.C.V.O., Westonbirt (gr. Mr. H. G. Alexander), showed *Cypripedium Nydia* (*Niobe Westonbirt* variety × *Charlesianum* var. Minnie), with deep-rose coloured upper sepal having a dark-claret median line and white tip and margin, honey yellow petals and lip suffused with chocolate-purple; also the new *Laelio-Cattleya Cranstounie Westonbirt* variety (see Awards).

J. GURNEY FOWLER, Esq., Gledbelds, South Woodford (gr. Mr. J. Davis), showed his very fine *Cypripedium Lceanum* J. Gurney Fowler, even greatly improved since it made its sensational debut, January 24, 1905, and was illustrated in the *Gardener's Chronicle*; his new *Cymbidium glebelandense* (*Schroderianum* × *insigne*, *Sandera*), a most interesting cross, though not so showy as some others. The growth is like a strong *C. insigne*, the inflorescence erect and sheathed as in that species, and bearing from one to four flowers, which, in the present imperfectly-developed state, were narrow-petalled, the sepals and petals greenish cream-white with faint rose shade, the lip having some dark lines on the side lobes and a red-spotted front; also two others (see Awards).

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed three very fine new hybrid *Cypripediums*, viz., *C. Col. Riordan*, with clear white upper half to the dorsal sepal, the lower part and the broad petals being spotted with dark purple; *C. Cupid*, probably a *C. belatulum album* cross with waxlike flowers bearing some purple spotting on the petals and upper sepal; add another nearest to *C. Rossettii* and having fine, greenish-yellow flowers with white upper half to the dorsal sepal.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), sent *Odontoglossum Wiganianum* Goodson's variety and a small *Odontoglossum* imported with *Oncidium macranthum*.

MESSRS. SANDER & SONS, St. Albans, showed *Cypripedium Goliath*, a large flower of the *C. Eson giganteum* class.

MESSRS. J. & A. A. McBEAN, Cocksbridge, sent *Odontoglossum crispum* Canoniae of the *O. c. Cooksonii* class, with large, pure-white flowers bearing evenly-distributed, large, claret-coloured blotches; and a good hybrid between *Cypripedium Beckmannii* and *C. Euryades*.

Sir JOHN EDWARDS MOSS, Roby Hall, Torquay, sent an example of an abnormally-developed hybrid *Odontoglossum*, in which two flowers were produced together, both of the labellums being arranged side by side and with the outer segments regularly arranged behind them.

Phaio-Calanthe Sedenii was shown from the ROYAL HORTICULTURAL SOCIETY'S GARDENS, Wisley.

AWARDS.

AWARD OF MERIT.

Odontioda Cooksonia (*C. Noezliana* × *O. ardentissimum*), from J. GURNEY FOWLER, Esq., Gledbelds, South Woodford (gr. Mr. J. Davis).—A very brilliant reddish-scarlet flower of perfect shape, the only trace of any other colour being a very slight white fimbriated margin and a pale rose tint on the front of the lip. The plant bore a fine spike of flowers with a lateral branch. The cross was originally shown from the Oakwood collection on its first flowering.

Laelio-Cattleya Cranstounie Westonbirt variety (*C. Harrisoniana* × *L. tenebrosa* Walton *Grange* variety), from Lieut. Col. Sir GEORGE L. HOLLORD, K.C.V.O., Westonbirt, Tetbury, Gloucestershire (gr. Mr. H. G. Alexander).—A very pretty and distinct hybrid and a worthy production, especially when it is remembered that the original cross flowered in 1899 from ordinary parentage never found favour. The present form would grace even the most select collection. The inflorescence bore six large flowers having the sepals and petals primrose-yellow, the white ground showing along the basal half of the midrib of the petals. The lip is white with a few dark lines at the base, and a veined rose-crimson blotch on each side in front of the tube.

CULTURAL COMMENDATION.

To Mr. J. Davis (gr. to J. GURNEY FOWLER, Esq., Gledbelds, South Woodford), for a very fine plant of *Cypripedium chrysotoxum* var. *Victor* (*Lathamianum* × *villosum*) with many flowers.

Fruit and Vegetable Committee.

Present: O. Thomas, Esq. (in the Chair); and Messrs. W. Bates, A. Dean, G. Kelf, E. Beckett, J. Willard, H. Hooper, J. Davis, J. Jaques, J. Lyne, F. Perkins, G. Wythes, and J. Harrison.

It was stated that two members of the Committee, Messrs. Hobday and C. Foster, were seriously ill, and the Secretary was asked to send a letter of sympathy to each member.

It is intended to exhibit from the Society's gardens a collection of forced vegetable stems at the next meeting.

Mr. W. H. DIVERS, The Gardens, Belvoir Castle, staged fruits of a seedling Pear named *St. Stephen*, the result of crossing *Marie Louise* with *Mme. Millet*. The fruits closely resembled those of *Marie Louise*. They were somewhat bruised in transit, and it was resolved that Mr. DIVERS be asked to send samples next season.

Small bundles of three varieties of *Asparagus* forced at Wisley were presented. All were sent by Messrs. BARR & SONS. These three were stated to be specially precocious, the best sample being *Mammoth*. The others were *Conover's Colossal* and *New White*.

The Earl of HARRINGTON, Elvaston Castle (gr. Mr. Goodacre), staged a collection of Grapes in 14 bunches, six of which were well-coloured *Muscats* of *Alexandria*, seven of *Black Alicante*, and one of *Appley Towers*. All the fruits were excellent and well-preserved specimens. (Silver Hogg Medal.)

The Earl of HARRINGTON also showed two varieties of *Tomatos* in clusters, one a bright-red round variety named *Elvaston Winter*, the other a selection of the yellow-skinned *Sunbeam*. All the fruits were solid and of medium size. Both varieties will be tested at Wisley gardens under glass and out-doors.

MESSRS. J. PLED & SONS, West Norwood, exhibited a collection of Apples. The fruits were excellent samples, and staged in 42 baskets and dishes. Cooking varieties were well represented, including *Lewis's Incomparable* (very handsome), *Annie Elisabeth*, *Mère de Ménage*, *Lane's Prince Albert*, *Homead Pearmain*, *Bismarck*, *Belle de Pontoise*, *Dumelow's Seedling*, *Newton Wonder*, and others. Amongst dessert varieties, we noticed good samples of *Lord Hindlip*, *Lord Burghley*, *Barnack Beauty*, *Charles Ross*, *Blenheim Pippin*, *London Pippin*, *Court Pendl-plat*, *Reinette de Canada*, and *Ashmead's Kernel*. (Silver Knightian Medal.)

Mrs. DENISON, Little Gaddesden (gr. Mr. A. J. Gentle), staged 124 bulbs of Onions in a few varieties, the bulbs being of good size and superbly finished; indeed, they could hardly have been shown better. The varieties were *Selector Ailsa Craig*, *Record*, *Rousham Park Hero*, *Holborn*, and *White Spanish*. (Silver-gilt Knightian Medal.)

Messrs. SUTTON & SONS, Reading, staged a large number of solid, white heads of Christmas White Broccoli, from their trial grounds. There were 48 heads: also as many very solid green heads of New Year Savoy, these being of medium size, very clean and handsome. The group also included blanched Chicory salading, to show its great value in mid-winter. (Silver Banksian Medal.)

Mr. W. SANDS, Hillsborough, Ireland, staged a collection of 20 baskets of Irish-grown Potatoes, to be planted at Wisley next spring for trial. Some of the dishes represented a second or catch crop planted immediately following an early spring batch, the second one in some cases giving the best crops. (Silver Banksian Medal.)

Mr. W. POUPART, jun., Twickenham, exhibited a collection of bottled fruits.

MARKETS.

COVENT GARDEN, January 4.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Eds.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices, including Anemone fulgens, Mimosa, Narcissus, and others.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and ferns and their prices, including Adiantum, Asparagus plumosus, and others.

Plants in Pots, &c. Average Wholesale Prices.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices, including Apples, Grapes, Lemons, Melons, Nuts, and others.

Christmas Fruits and Preserves.

Table listing various Christmas fruits and preserves and their prices, including Figs, Nuts, Dates, and others.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices, including Artichokes, Aubergines, Beans, and others.

THE NORTH OF ENGLAND HORTICULTURAL.

IN connection with this new horticultural society, which is to have its headquarters at Leeds, the following suggestions for a programme are put forward by the Secretary, the Rev. J. Bernard Hall:—

- 1. Affiliation to the Royal Horticultural Society, co-operating with them in the North, and adapting their rules for judging, &c.
2. Annual show at Leeds—the strategic railway base of the North: (a) two days, Wednesday and Thursday, August 9 and 10.
3. Annual fruit congress, on the invitation of some local society, e.g., at Carlisle, on August 30 and 31, 1911.

TRADE NOTICES.

JAMES DICKSON & SONS.

The trustees of the estate of the late Mr. Alexander Milne, sole partner of the firm of James Dickson & Sons, nurserymen and seedsmen, Edinburgh, have disposed of the business as at December 1, 1910, to James Stuart, who has been for the past 32 years with James Dickson & Sons, and to Eric Pringle Laird, son of the late Mr. David Pringle Laird, nurseryman and seedsmen, late of Pinkhill, and 17, South Frederick Street, Edinburgh.

STEWART & BREWELL, LTD.

This company has been registered with a capital of £1,000 in £1 shares, to take over the business of bulb merchants, seedsmen, florists, and nurserymen, carried on by E. Steward, as Edward Steward & Co., at 57, Carrington Street, Nottingham.

STANLEY & CO.

Mr. H. Stanley's services with this firm terminated on December 19, not 20 (see p. 491). Mr. John Cowan, jun., will take over the management on the 23rd inst. In future the firm will be known as Hassall & Co., late Stanley & Co. A. Hassall.

DEBATING SOCIETIES.

BRISTOL AND DISTRICT GARDENERS'.

A meeting was held on December 29 at St. John's Parish Rooms; Dr. Shaw occupied the chair. Mr. Stafford, schoolmaster, Carleton, Newport, gave a lecture on "Protective Colouring of Insects." The lecturer gave a brief life history of the lepidoptera, of which family he has made a study for 21 years. Large numbers of British moths and butterflies, also foreign specimens, were displayed in cases. Mr. Stafford stated that insects owe their colour to pigments embedded under the skin, and that different foods produced different colours in the insects.

REMARKS.—There is an increasing demand for Apples of all grades, and prices have advanced. The supply of Peas is becoming short. Grapes are nearly finished. For Tomatoes the market depends almost entirely upon consignments from the Canary Islands; the fruits are meeting with a fairly good demand. Peaches and Nectarines are arriving from the Cape, the condition of the fruits being all that could be desired. The Vegetable trade shows an improvement in prices. Trade, generally, is good, considering the time of year. *E. H. K., Covent Garden, January 4, 1911.*

REMARKS.—Prices are the same as last week, but there is a tendency for an increase in the case of the cheaper varieties. *Edward J. Newbon, Covent Garden and St. Pancras, January 5, 1911.*

COVENT GARDEN FLOWER MARKET.

French flowers have been arriving in large quantities. I was offered blooms of Paper-white Narcissus this morning (Wednesday), at the close of the market, very cheaply. Many English grown Narcissus are on sale, including the Double Van Sion, Golden Spur and Henry Irving. Tulips are abundant and the prices vary considerably. Roman Hyacinth is well supplied. Lily of the Valley was on sale by street hawkers at 6s. per dozen bunches, but this does not represent the fair market value, yet it indicates that there is a surplus. Carnations are sold cheaply compared with their value a few years ago. Supplies of Chrysanthemums hold out well, and prices were very low this morning, large quantities were not sold for lack of purchasers. Good Roses are not quite so plentiful, and prices have risen slightly. Narcissus is not grown so extensively as formerly, The Bride and Frau Karl Proschka taking its place to a great extent, yet the older variety remains a favourite with some florists. Mme. Abel Chagnay is always in demand, and the best flowers command good prices. Perle des Jardins, Sunset, and Sunrise are amongst those now grown extensively for market purposes. Tulips are offered at low prices compared with what they are usually worth in January. Richardias are also offered cheaply. Lilac (Syringa), both white and the normal colour, is procurable. The white variety is the ordinary Persian Lilac, grown in darkened pits or houses. There has been no demand for Pansettias, and their prices have fallen. The market has been supplied with most cut flowers in excess of the demand, and growers from the provinces will, no doubt, be disappointed with their "returns."

POT PLANTS.

Trade has been very quiet. Forced bulbs are a feature, and especially Tulip, but the prices have hardly been equal to what the first consignments usually make. Narcissus in pots are fairly good. Lily of the Valley is grown chiefly in boxes, but the prices are only slightly in excess of those realised for cut flowers. Indian Azaleas are seen in well-flowered plants, and rather higher prices are asked for them than usual. Ericas are well supplied. Chrysanthemums vary in quality, good plants are becoming scarce. Marguerites are procurable in well-flowered plants. Palms are likely to realise good prices in the future, for some nurserymen, who only grow them when seed is cheap, are not keeping up a succession of young plants. The supplies of Ferns are well sustained by the leading growers, and the prices vary but little. *A. H., Covent Garden, January 4, 1911.*

LAW NOTE.

A DISASTROUS CUCUMBER CROP.

At the offices of the Official Receiver for the Brentford district, before Mr. Cecil Mercer, Senior Official Receiver, a meeting of creditors was held under the failure of Edward Albert Bannister, of 5, Upper Gratto Road, Twickenham, nurseryman, late of Bird's Farm, Collier Row, Romford, Essex, and Pope's Nursery, Pope's Avenue, Twickenham. The statement of affairs disclosed liabilities expected to rank against the estate for dividend amounting to £538 11s. 6d., and the assets were estimated to produce £5. Debtor accounted for his deficiency by loss in carrying on business from December 9, 1909, £37 11s. 6d.; household expenses of wife and four children, £156; loss of crop of Cucumbers, owing to disease, £300; expenses of advertisement, £100, thus making the deficiency of £593 11s. 6d. The Official Receiver, after reading over the proofs of debts lodged, stated that the estate would remain in his hands for summary administration in the usual manner. In reply to questions put by the Official Receiver debtor stated that since he started at Pope's Nursery he could not say exactly what business he had done, because he had kept no books. He had no vans of his own, but always hired them locally whenever he required them. He had done a considerable amount of business in seeds and plants. Most of the debts he had incurred were in respect of goods supplied. The Official Receiver, who has been in the habit of purchasing from this nurseryman, stated that some of them have been grown and some sold

by mail order trade. Debtor further stated that he had had a good deal of bad luck with his crops and that was the cause of his trouble. Most of the seeds were sent away in the mail order trade. He had a large crop of Cucumbers, but, unfortunately, they were a failure. In June or August last he discovered a disease among his Cucumbers, with the result that all his labour and trouble on them had been wasted. He estimated his loss in that respect at £300. He had about 500 feet of Cucumbers under glass. The labour alone put into them amounted to about £150. He could not say exactly how much money he received weekly through the mail order trade. Some weeks it was £10, and other weeks it was £15, and it had even been as much as £50. Questioned about an item of £163 paid into his bank on June 14, debtor stated that it was the proceeds of the mail order trade. He used to advertise in about ten papers, and supplied seeds and plants to amateur gardeners. He bought plants and seeds in Covent Garden market, and then sent them out to all parts of the country to his mail order customers. He always bought in bulk, and then repacked them in small quantities before sending them out.

ENQUIRY.

APPLE "SAUNSON."—In a Court Roll of the Manor of Duffield, Co. Derby, dated November 29, 1520, I came up on the following:—"Paying (as rent) annually one measure of Apples, called a *strike of Saunsons*, growing upon the land aforesaid." The words in italics were in English, the remainder in Latin. Can any reader enlighten me as to what was a Saunson? A *strike* is a measure equal to about two pecks. *C. W. Firebrace*

ANSWERS TO CORRESPONDENTS.

CLIMBER FOR A NORTH-WEST WALL: *Argus.* The following plants would be suitable for your purpose.—Ivies, especially the small-leaved varieties; Jasminum nudiflorum, J. officinale; Lonicera flava; Pyrus japonica, P. Mandai; Bridgesia pictata; Camellias; Crataegus Pyracantha Lalandi; and Roses, such as Gloire de Dijon, Longworth Rambler, Felicite Perpetue, Ruby Queen, William Allen Richardson, Rene Andre, Mme. Alfred Carriere, and Zephyrine Drouhin.

FORCING OF FLOWERING PLANTS: *A. W.* With a moist atmosphere and a temperature ranging from 60° to 65° at night and 70° by day, it may be possible to get Azaleas into flower by the middle of February. Choose Deutsche Perle as the most dependable white, and whatever other colour may be preferred select plants with prominent buds. In respect to Lily of the Valley it is by no means certain, but if the crowns are vigorous you may succeed. Choose crowns in preference to clumps, and only use the strongest. Pot them into 6-inch pots and plunge these in a gentle heat, covering the crowns with a light material, such as Cocoa fibre. The same temperatures as recommended for the Azaleas will be suitable. A better and safer proceeding to ensure getting the flowers in time would be to obtain retarded crowns—these will expand their flowers in four weeks after the commencement of forcing at this period of the year. Hyacinths, Tulips and Narcissus will also need all the time available. These should be started steadily in a temperature not exceeding 50°, and in 14 days time the heat may be increased by 5°. Before either of these bulbous plants show any tendency to become drawn or to elongate their flower-stems unduly, let them be placed upon shelves as near to the glass as possible. Choose the early sorts of each in preference to later varieties. In respect to Cinerarias, it will depend entirely upon their present forward condition. If the flowering shoots are now 6 inches in height, it may be possible to get some flowers open, but it is doubtful.

GARDENER'S WAGES: *E. J. M.* The amount of remuneration paid to a hired gardener usually varies according to the size of the place and the responsibilities imposed by its arrangement.

The minimum wage recommended by the British Gardeners' Association for a gardener is 30s. per week, with suitable housing accommodation. The salary of under-gardeners varies greatly, and may range from 16s. to 30s. per week with bothy provision.

MALFORMATION IN GOOSEBERRY SHOOTS: *S. C.* This malformation is often seen in Gooseberries, and similar trouble has been noticed in the case of Apples and vines. It is not due to either an insect or fungus, but is the result of some physiological cause, which produces bud suppression in the malformed growths. Spraying will do no good. Dress the soil with lime.

NAMES OF FRUITS: *S. R. H.* Apple, probably Newtown Pippin.—*R. Park.* 1, Forge Apple; 2, Alfriston.—*S. Bannister.* Wadhurst Pippin.—*Ber. Hall.* Apples (green) Reinette Franche; (yellow) Waltham Abbey Seedling. Why not number your specimens?—*John Butcher.* Ribston Pearmain (not Ribston Pippin).

NAMES OF PLANTS: *A. Y.* Dictamnus origanum.—*Cape Bulb.* Ornithogalum lacteum.—*L. G. P.* Lopezia miniata.—*H. E. C.* Nerine crispa.—*H. G. Wilt.* Salvia leucantha.—*O. O.* 1, Polystachya luteola; 2, Mystacidium filicorne; 3, Cnema triptera; 4, Oncidium vaniferum.—*H. P., Cardiff.* Zygopetalum Mackayi.—*H. P.* Catsetum maculatum.—*Robuck.* Cypripedium villosum.—*T. A. H.* 1, Veronica angustifolia; 2, V. Andersonii.

ORCHID BORER BEETLE: *J. G. D.* The beetle damaging the Dendrobiums is known as Xyleborus morigerus, Blanford. It was wrongly named Xyleborus perforans, Wollaston, by the writer of an article on this pest in the Board of Agriculture Journal (Vol. IV., No. 4, pp. 474-476). It appears mainly to attack and destroy various species of Dendrobium.

ROSES: *H. C.* It is difficult to understand how vigorous growths fail to flower, as the varieties are amongst the freest blooming sorts. Can it be that the growths are mere suckers? If you send a few of the shoots it may help us to give you a more definite reply.

TULIPS DISEASED: *C. M.* The plants are attacked by Botrytis (Sclerotium) disease. The first stage of the disease appears as a whitish fluffy mould, which changes to a brown colour, and develops numbers of spores. This is called the Botrytis or summer stage. The mycelium or spawn grows up inside the stem, and forms numbers of black, solid bodies, sometimes as large as a grain of corn, which are known as Sclerotia. When the plant decays at the end of the season, the Sclerotia fall to the ground, and produce spores which infect other plants. Diseased plants should be burnt, and accumulations of vegetable matter should not be allowed in a garden. Gaslime or quicklime applied to the land will be of benefit in checking the disease.

TURF CUTTING: *J. A. W.* The cost of turf cutting will necessarily vary according to the locality, and will be regulated to some extent by the labour conditions of the district. But it may be taken approximately at 1s. per hundred turves, or, roughly, one rod. Where the turves are desired to be especially regular and even, the cost would be 1s. 3d. As each acre will contain 160 rods, the price per acre will vary from £8 to £10.

WORMS IN CHRYSANTHEMUM POTS: *E. T.* The worms are harmful to the roots of various plants. They belong to the genus Enchytraeus, and one is known as the Aster worm (Enchytraeus parvulus), which lodges under the epidermis of the roots and feeds on the juices and tender substances. Another species, E. agricola, also does much harm to plant life. These worms may be destroyed by dressing the soil with salt, at the rate of 1 ton to the acre. Lime water, made by mixing one pound of quicklime to one gallon of water, will also kill them. The lime requires to be mixed well, and the liquid should be strained and applied in a clear form. Vaporite is destructive to these worms.

AMERICAN HAWTHORNS.

SOME NEW ARBORESCENT SPECIES.

THE tomentosa group of Crataegus includes a very large number of species, which are mostly distributed east of the Mississippi River. They are particularly abundant in the Province of Ontario, Canada, from Toronto to Port Huron, where they form a very important part of the vegetation. The tomentosa and Crus-galli groups are the latest in the genus to bloom, and the various species in the two groups flower about the same time, which is usually from May 28 to June 15. The general characters of the species in the tomentosa group are perhaps more readily detected at a glance than those of any other. They are mainly characterised by leaves obovate to ovate and cuneate to rounded at the base; small flowers, in tomentose or villose corymbs rarely glabrous, opening late; fruit obovate to sub-globose, or short-oblong, orange-red, or scarlet, usually becoming succulent at maturity; nutlets, with longitudinal grooving on their ventral faces. This feature of the nutlets is a remarkable and constant characteristic of the

different species in the group, which includes some splendid plants for park and garden decoration.

The following species are included in the tomentosa group:—

C. CRATAEGUS ADMIRANDA.—This species is an arborescent shrub, growing 12 feet high, with spreading branches forming a round-topped head. The leaves are obovate to oval, cuneate at the base, tapering considerably in the petiole, and about 3 inches long to 2 inches wide. The 20-stamened flowers, with pale-pink anthers, are produced on densely tomentose corymbs, and usually open about June 7. The fruits are short-oblong, lustrous, bright-red, developed on spreading, reddish stalks, and they ripen about the second week in October. They are much larger than in most of the other species of this group. The type plant grows on the banks of the Niagara River, at Niagara Falls, on the New York State Reservation, and it appears to be mostly confined to this locality, although a Crataegus found at Canandaigua Lake, N.Y., last year was doubtfully referred by me to this species.

C. BALKWILLII.—This Hawthorn is a slender tree 18 to 20 feet high, with a trunk 6 feet long, and spreading, ascending branches forming a thin and irregular head. The leaves are obovate to elliptic, gradually narrowing on the petiole, 3 inches long and 2½ inches wide. The flowers, with five to eight stamens, bearing pink anthers, are borne on long pedicels on few-flowered, hairy corymbs, and open about June 4. The orange-red, roundish fruits, produced in small clusters, ripen at the end of September. The type tree grows in a rich shady wood near the city of London, Ontario, Canada, and it appears to be confined to that locality. The species was named by Dr. Sargent, in compliment to John Arthur Balkwill, of London, Ontario, who has a considerable knowledge of the Crataegus in his locality.

C. CALVINII.—This is commonly an arborescent shrub about 12 feet high with flattish, spreading branches, forming a handsome, globular head. The leaves are generally obovate, cuneate at the base, 3½ inches long and 2½ inches wide. The 20-stamened flowers with light-rose anthers, are produced on densely villose corymbs during the first week in June. The sub-globose fruits, borne on stout, spreading reddish pedicels, are bright, lustrous, cherry-red, and ripen during the first week in October. The type plant grows wild on the banks of the outlet of Canandaigua Lake, N.Y., and is a fairly common species in that vicinity. The fruits of this species are distinctively succulent, and make a remarkably handsome and brilliant display in the month of October. It was named by Dr. Sargent, in compliment to Calvin Cook Laney, the superintendent of the Rochester Park system.

C. DELECTABILIS.—This species forms a handsome tree 18 to 20 feet high, with a trunk 10 inches in diameter at the base, and stout, spreading branches, forming an open, irregular head. The old stems and main trunk are conspicuously covered with light gray, scaly bark. The leaves are ovate to oval, gradually narrowed at the cuneate base, often 4 inches long and 3 inches wide. The flowers have six stamens, which possess cream-white

anthers. They are borne on almost glabrous pedicels and open about June 4. The obovate, scarlet fruits, marked by pale dots, are suspended on long drooping pedicels, and ripen about the end of September. The type tree grows on the Weston Road in the northern suburbs of Toronto, Canada. This Hawthorn is very showy when covered with its scarlet fruits in the autumn.

C. DEWEYANA.—This species forms a tree sometimes 25 to 30 feet high, with a trunk 5 to 6 feet long, and 10 inches in diameter at the base. The lower branches are very stout, horizontal, and slightly drooping, and the upper branches are end slightly, forming a wide, open, and picturesque head. The extremities of the branches are usually remotely extended from each other on the head of the tree, giving it a marked individuality. The leaves are very broadly obovate to ovate, abruptly narrowed at the sometimes oblique base, and are about 4 inches long and 3½ inches wide. The flowers are borne on loose, villose corymbs, the time of blooming being about May 30. The stamens number 10, and have reddish anthers. The roundish sub-globose fruits of a lustrous scarlet colour, produced on drooping pedicels, and ripening after the middle of September, are conspicuous objects until the middle of October. The type tree grows in rich, alluvial soil, in competition with strong-growing forest trees, on the south side of the city of Rochester, N.Y., and has lately been found growing in the Campus of Cornell University, or on grounds adjacent thereto. In its distinct arborescent characters, handsome foliage, and showy flowers and fruits, this is perhaps one of the most beautiful of all the tomentosa species. Dr. Sargent named it in compliment to Chester Dewey, a botanist and student of natural history, who was for many years professor of chemistry and natural philosophy in the University of Rochester.

C. DIVERSA.—This is commonly an arborescent shrub about 12 feet high, with erect stems and small ascending and slightly spreading branches forming an open head. The obovate leaves, with narrowed cuneate base, are usually 3 inches long and 2½ inches wide. The flowers, which have 12 to 20 stamens, with rose-coloured anthers, are produced in hairy corymbs about June 15. The fruits are oval to obovate, lustrous crimson, on hairy, drooping pedicels, and ripen about the end of September. The type plant grows at Cooper's Plains, Steuben County, N.Y., on a hillside pasture, and is not at present known outside that locality.

C. EFFERATA.—This species is usually a tall, arborescent shrub from 16 to 18 feet high, with erect, spreading branches forming a compact oval-shaped head. The oblong-ovate leaves, with an abrupt cuneate base, are often 4 inches long and 3 inches wide. The flowers, which open about May 30, are produced in compact, hairy corymbs. The stamens number 16 to 20, the anthers being rose-coloured. The sub-globose scarlet fruits are suspended on long, drooping, hairy corymbs, and ripen about October 5. The type plant grows on the banks near the outlet of Henlock Lake, Livingston County, N.Y., and the species seems to be scattered throughout that region. *John Dunbar.*

(To be continued.)

ORCHID NOTES AND GLEANINGS.

ANGRÆCUM PELLUCIDUM

ANGRÆCUM PELLUCIDUM (see fig. 13) was introduced from Sierra Leone as far back as 1842, but the plant is still rare in gardens. The flowers are not large, like those of some of the other species, such as *A. sesquipedale*. Nevertheless, a specimen in bloom is very attractive. The plant, from which the illustration shown in fig. 13 was prepared, was exhibited by J. S. Bergheim, Esq., Belsize Court, Hampstead, at the meeting of the Royal Horticultural Society, on December 6, and the Orchid Committee awarded it a Botanical Certificate. The specimen was attached to a small portion of wood, and was suspended to allow the drooping inflorescences of creamy-white flowers to display their beauty. But *Angræcum pellucidum* may be grown in a pot with equal success, although the receptacle needs to be suspended when the plant is in bloom. A specimen in Sir Trevor Lawrence's collection at Burford, cultivated in a pot, formed the subject of the Supplementary Illustration in the issue for August 10, 1895.

LÆLIO-CATTLEYA TEIGNMOUTHIIENSIS.

SPECIMENS of this cross from *Lælio-Cattleya amanda* and *Cattleya labiata* are sent us by Eustace F. Clark, Esq., Chamonix, Teignmouth, who writes:—"There have been only three seedlings, which all germinated in 1901 on a pot of Coconut fibre." The better flower has a resemblance to *Cattleya maxima*, the other, in the tubular form of its labellum, showing a reversion to *C. intermedia*, which, with *L. Boothiana*, was supposed to be the parents of *L.-C. amanda*. The better flower shows the veining of *L. Boothiana*. The sepals and petals are silver-white, tinged with lilac; the lip rose colour, with darker veining, and a tinge of yellow in the centre.

LÆLIO-CATTLEYA FERRIPAL.

UNDER the above name, Mr. Clark sends a flower of a hybrid from *L. Perrinii* and *Lælio-Cattleya Pallas*. It is flowering for the first time, and is of indifferent quality in its present condition. The sepals and petals are pale lilac; the lip has the side lobes thrown back, and the purple-tipped front deflected, as in *L. Perrinii*.

LÆLIO-CATTLEYA CRANSTOUNÆ "WESTONBIRT VARIETY."

(See fig. 17, p. 27).

THE Award of Merit given to this fine production of Lieut.-Col. Sir George L. Holford, K.C.V.O., and reported last week (see *Gardeners' Chronicle*, p. 14), was raised by the Council to a First-class Certificate. As a general rule it can scarcely be doubted that the Orchid Committee are quite liberal enough in their awards. At the same time, this charming novelty thoroughly deserves the First-class Certificate.

CYPRIPEDIUMS AS WINTER FLOWERS.

THE value of a section of this large genus for winter blooming is well shown in a photograph of a *Cyripedium* house, taken recently in the gardens of Fred Hardy, Esq., Ashton-on-Mersey, a copy of which has been sent us. There are about 2,500 blooms, many of them of plants of the best varieties of *Cyripedium insigne* and *C. Lecanum*, *C. Eurycles*, and other winter-blooming kinds. The plants are evidently in an excellent condition, and many of them are large specimens.

LÆLIO-CATTLEYA BELLA ALBA

THIS hybrid (from *Lælia purpurata alba* and *Cattleya Warneri alba*), shown by Messrs. Charlesworth & Co., Baywards Heath, proves the advantage of going over the best-known crosses again, selecting as the parents the choicest varieties procurable. The use of albinos in this case has resulted in a beautiful pure-white flower with a bright purplish crimson lip.

FIG. 13.—ANGRÆCUM PELLUCIDUM: FLOWERS CREAMY-WHITE.

HYBRIDS RAISED AT KEW.*

FOR many years past a number of hybrid plants have been raised at Kew, and in view of the general interest and importance of such work it has been considered advisable to bring together into as complete a record as possible the successes and failures in hybridization at Kew. In the following account, in order to facilitate reference, the hybrids have been arranged in alphabetical order, and in all cases the name of the female parent is placed first. They have been produced, as the list shows, in all departments of the Royal Botanic Gardens.

Begonia Pink President Carnot (*B. President Carnot* × *B. kewensis*).—This hybrid, raised in 1902, first flowered in 1904. It resembles the female parent in habit, in that the female flowers, which are pink in colour, remain on the plant for some time; in addition to this, the male flowers, which in the mother plant do not open properly and drop off at an early stage, remain on the plant and open properly as in *B. kewensis*.

Begonia (*B. coccinea* × *B. kewensis*).—The hybrid was raised in 1902 and flowered in 1904. Habit intermediate between the two parents. The dull scarlet flowers are disposed in slender, pendulous inflorescences, as in *B. coccinea*.

Bravoa kewensis (*B. geminiflora* × *B. [Prothyranthes] Bulliana*).—The hybrid was produced in 1894 and flowered in 1899. Plant tufted, deciduous. Leaves 2 feet long, 1 inch in diameter. Inflorescence 4 feet high, bearing flowers in the upper part only. Perianth tubular, dull brownish-red on the outside, and yellow on the inside of the tube. (See note in *Gardeners' Chronicle*, 1899, xxvi., 112.)

Brunsvigia (*Brunsvigia Josephine* × *Amaryllis Belladonna* var. *kewensis*).—One seedling was obtained from this cross, which was made in September, 1893; it has not yet flowered, but is distinct in habit from both parents.

Calceolaria kewensis (*C. Jefferies' hybrid* × *herbaceous varieties*).—This cross was made in 1904, the seedling flowering in 1905. The plants were grown a second year and flowered profusely in May, 1906. *C. kewensis* seeds freely and comes true from seeds. The plant is figured and described in the *Gardeners' Chronicle*, 1906, xxxix., 390, fig. 153.

Calceolaria (*C. Clibranii* × *herbaceous varieties*).—This cross was made in 1906, and the seedlings flowered the following spring. The blooms are about the same size as those of *C. kewensis*, but both habit and leaves are distinct. The pollen of six distinct colours of the herbaceous varieties was used on *C. Clibranii*, the result being a fairly wide range of colour and spotting in the flowers.

Callispyche kewensis (*C. mirabilis* × *C. aurantiaca*).—Raised in 1898, flowered in 1901, seedlings show very little variation, and are intermediate in characters between the parents. The flowers are buff-yellow in colour, with long pendulous stamens of a creamy-white shade. The flowers of *C. amabilis* are white, while those of *C. aurantiaca* are orange. The hybrid is fertile, and seedlings have been raised from it.

Campanula (*C. thyrsoides* × *C. spicata*).—Plants intermediate in character between these two species appeared amongst a batch of seedlings raised in 1900 from seed of *C. thyrsoides* which had ripened in the Alpine House. The cross was probably effected by insects, the two parents being in flower at the same time in the house. Plants flowered the following year, having a longer, looser inflorescence than is usual in *C. thyrsoides*, while the flowers were also intermediate in character. Seeds saved from the hybrids did not retain their character, but reverted to *C. thyrsoides*.

Cheiranthus hybridus (*C. mutabilis* × *C. Cheiri*—*yellow variety*).—A few seeds were obtained from this cross, made in 1897, and from one, *C. hybridus* was raised. This grows into a many branched plant of more vigorous habit than the female parent. The fragrant flowers are small and borne in slender racemes in spring. They are purple throughout the early stage, but turn to a yellowish colour with age. It requires greenhouse culture.

Cheiranthus kewensis (*C. hybridus* × *C. Cheiri*—*red variety*).—The cross was made in May, 1899, and one plant was raised which flowered in January, 1900. Its leaves are similar to those of *C. Cheiri*, but the flowers are intermediate in character. The flowers are fragrant and borne freely in long racemes. They vary in colour, at different stages, from yellow to brown and then to purple. It is usually grown indoors and shows to the best advantage in sunny weather during February and March. A description of the two hybrids was published in *The Garden*, 1901, lix., 173.

Cynorchis kewensis (*C. purpurascens* × *C. Lowiana*).—The seedlings raised from this cross, made in 1901, flowered in 1903. In habit they resemble *C. Lowiana*, the flowers being intermediate in size and dull purple-red in colour.

Cytisus kewensis (*C. Ardoinii* × *C. albus*).—This hybrid was obtained in 1891 through insect agency, and appeared among a batch of seedlings of the former parent. It is now widely cultivated in gardens. The habit is quite prostrate and the flowers of a pale sulphur-yellow.

Cytisus Beanii (*C. Ardoinii* × *C. purgens*).—This cross was also effected by some insect in 1892. It is a low bush with golden-yellow flowers.

Cytisus Dallimori (*C. scoparius* var. *Andreanus* × *C. albus*).—The mother plant of the cross was grown in a pot and fertilised under glass in 1900. Only two plants were raised, one of which had pale yellow flowers and showed no influence of the mother plant in colour, but was of great vigour. The other, a much weaker plant, flowered in 1904 and had pale purple blossoms, and has been named *C. Dallimori*. Grafted on stocks of *Laburnum*, the hybrid is now showing plenty of vigour and is undoubtedly one of the most distinct and beautiful of the taller Brooms. It was given an Award of Merit at the Temple Show of 1910. (See *Gardeners' Chronicle*, 1910, lviii., 397.) The hybrid is fertile, but it is not yet known whether it will breed true.

Disa kewensis (*D. grandiflora* × *D. tripetaloides*).—This hybrid was the result of a cross effected in 1891, and flowered in 18 months from the sowing of the seed. The flowers are intermediate in colour, 1½ inch in diameter, with bright rose lateral sepals; the dorsal sepal is hooded as in *D. tripetaloides*, light pink in colour, with a few light red spots. The labellum is concave, pink, shading off at the base to pale yellow, and spotted with light red. Figured in *Gartenflora*, 1903, t. 1510.

Disa Premier (*D. tripetaloides* × *D. Veitchii*).—This plant resulted from a cross made in 1891. *D. Veitchii*, the male parent, is itself a hybrid between *D. grandiflora* and *D. racemosa*. The flowers are rich rosy-crimson, larger than those of *D. racemosa*. It was exhibited at the Royal Horticultural Society's meeting on October 10, 1893, and received a First-class Certificate.

Epidendrum kewense (*E. canthium* × *E. cicutum*).—The reverse cross was also made. The first seedling from this cross, made in 1899, flowered in 20 months from germination. These hybrids showed diverse shades of colouring, the bulk of them being dull red or buff, suffused with yellow. A few flowers were self-pollinated and also recrossed with both parents. For further information, see *Orchid Review*, 1907, pp. 58, 122.

Freesia kewensis (*F. Armstrongii* × *F. Lechtlinii*). This cross was made in 1903, and

the seedlings flowered in the following year. The flowers are pale lilac-pink, suffused with pale yellow in the throat, about 1 inch in diameter, with a long tapering tube and spreading limb. The habit of the hybrid is erect and slender, as in *F. Armstrongii*.

Gladiolus (*G. deinceps* × *G. primulinus*).—The cross was made in 1906, and the seedlings flowered in 1909-10. The seedlings all showed the predominance of the male parent in the long slender inflorescence, glaucous foliage, and in the ground colour of the flower, which is yellow. The red stripes which are so characteristic of the mother plant are only faintly developed in the hybrid. The reverse cross was made but no good seeds were obtained.

Gladiolus (*G. Colvillei albus* × *G. primulinus*).—The cross was made in 1906, but only one plant flowered this year. Habit intermediate; leaves glaucous; flowers buff-coloured, large and reflexed as in *G. Colvillei*, with deeper markings in the throat. The seedlings are mostly weak and difficult to grow.

Gladiolus (*G. primulinus* × *Lemoine's hybrid*—*white variety*).—The cross was made in 1906, and seedlings flowered in 18 months to two years from the date of germination. Habit of seedlings intermediate; flowers with bright scarlet ground colour, heavily blotched with pale lemon-yellow on the lip and throat. A few of the seedlings showed distinct striation with a darker shade of red. The flowers are about 3 inches in diameter and show the spreading or reflexed segments of the male parent.

Kalanchoe kewensis (*K. flammula* × *K. Butii*).—Crossed in 1901 and flowered in 1902. The flowers are bright rose-pink in large corymbose cymes about a foot in diameter. Plant 2-4 feet high. The remarkable feature of this plant is that although both its parents have simple leaves, the hybrid has several leaves with one or two pairs of pinnae. It is described and figured in the *Annals of Botany*, xviii., pp. 435-441, pl. 21 23.

Kniphofia kewensis (*K. pauciflora* × *K. Macowanii*).—Seeds sown in October, 1892. The plants flowered in October, 1893, the inflorescence being longer and looser than in *K. pauciflora*, while the flowers are tinged with red. It was published under the name of *K. pauciflora* × *Macowanii* in the *Gardeners' Chronicle*, 1893, xiv., 424.

Lilium kewense (*L. Brownii* var. *chloraster* × *L. Huryi*).—Raised in July, 1897, seeds were sown the following November, and the first flower opened July 19, 1900. The hybrid resembles *L. auratum* in habit, but the flowers are pale buff, with a few brown spots on the inner side of the segments. It is described and figured in *The Garden*, 1900, lviii., 99.

(To be continued.)

THE ROSARY.

DIFFICULT ROSES.

THE pleasant chat about "difficult" Roses by *R. P. S.* tempts me to add somewhat to his list, as I think some of the loveliest Roses are just those that will not content themselves with routine treatment, and are therefore far too little known.

Perhaps the loveliest of all golden Roses, and I speak advisedly when I call it golden, is the Tea Rose *Georges Schwartz*. I must own I have never seen it in beauty in England, but the reason is that it will not grow on the Binar stock so universally employed nowadays. Why not then buy it on some other stock, and so give your friends and self the pleasure of a possible success and surprise? It succeeds admirably on the India major stock so much used in southern countries, but then requires a moist soil to pass the summer droughts without injury. It will

* Reproduced from *Kew Bulletin*, No. 9.

† *B. kewensis* is a chance seedling or hybrid which originated at Kew about 15 years ago. It most nearly resembles *B. undulata*.

also grow vigorously when budded on *Rosa bracteata* (the Macartney Rose) and on this stock is an admirable winter bloomer. Its immense, golden petals are so solid that it withstands the winter dews unimpaired, but it is not long-lived on this extra-vigorous stock, so that it should be renewed every third or fourth season. It will grow on the Banksian stock also when not too fully exposed to wind and sun, and I suspect that some of the Himalayan Roses would be congenial to it. But the most essential thing is that it must not be pruned! This is the cardinal point. You may thin out some of the oldest wood now and again, but you must not cut it back; if you do, you will see at once the results in lessened vigour. Consequently, it must be grown under glass in most parts of England, and, if I gardened in England, I would try it in a cold house rather than be without it.

Then there comes the lovely, though not golden Rose "Cloth of Gold"—whose lemon-coloured petals shade to clear yellow in the centre—which should still find a place on some wall too hot for other Roses. It also must not be pruned in the ordinary way, but only thinned out now and again, and, if it scrambles among other and evergreen climbers, you will have the greater probability of seeing its fair beauty. Here, too, there is an indispensable thing required for its success, and that is, iron in the soil. It is quite hopeless to get a really beautiful flower on this Rose without plenty of iron in the soil—a curious fact in the culture of this Rose.

A very favourite Rose of mine is the tiresomely-named *La France de 1889*, one of the few Nabonnand-raised Roses that can give an exhibition bloom. It thrives best on a wall with an easterly aspect, and, in such a position, will climb to a considerable height. In England this Rose is best when only thinned out, rather than pruned, but in the South of France it may be cut down to the ground in the month of August, and the strong shoots that come up will give some superb blooms in January or February on their extreme ends, and later in spring a quantity of bloom from the side growths. Its fragrance and rich rose-red colour in winter are remarkable, while in warm weather the colour rapidly turns purple.

There is a promising Rose lately introduced called *Mary Countess of Ilchester* that will, I hope, prove even more valuable for winter bloom than the old *La France de 1889*. It has a stiffer and better habit, while retaining many of the good points of its precursor. There is a decided likeness between the two Roses when well grown, and this will, I think, prove the harder of the pair.

Comtesse de Turenne, mentioned by *R. P. S.*, is as great a favourite with me as with him for winter bloom; indeed, I do not know a more beautiful Rose of its soft, clear, pink colouring. In southern lands, this Rose needs moisture. There, it makes a fine pillar, with its robust shoots and glossy foliage. It stands severe pruning for the winter bloom, if only one good shoot be left untouched, to "draw the sap," as it were. Without this precaution, it is inclined to refuse to start in autumn. On a wall, it should be a very useful Rose in England for autumn bloom, but it will not stand drought at the root, and its petals are so numerous that they do not stand heavy dews or rains without suffering.

Souvenir de Léonie Viennet seems to me quite as beautiful as *E. Veyrat Hermanes*, and will give an abundant harvest of its exquisitely-tinted blooms when grown on a sheltered wall and well treated in the matter of soil and manure. Its great fault is that it is only a summer bloomer; it would be quite indispensable if it could be persuaded to give a second crop, for its apple-blossom, rose, and apricot tints are so beautiful, and the shape and size of the blooms above average. This Rose, like *Cloth of Gold*, needs a good deal of manure to bring out its beautiful tints, and thrives on a strong soil. *Edward H. Woodall, La Seta, Nise.*

SANDALWOOD.

AN OPPORTUNITY FOR PLANT PATHOLOGISTS.

THE Sandalwood tree (*Santalum album*) has some pretensions to beauty, its delicate foliage responding readily to the amount of light falling upon it, the dark green leaves of shady places becoming almost clear yellow when exposed to the bright sunlight. It is a handsome little tree, 20 feet to 30 feet high, whether bearing masses of small, dark-brown flowers or laden with shining fruits, green or red or black, according to their stage of ripeness. Geographically, its range is limited to the Indian peninsula, and here its habitat is determined by climatic conditions. A mean temperature of 74° Fahr., a rainfall of 20 to 40 inches, and an elevation of from 2,000 feet to 4,000 feet appear to suit it best:

limb being not infrequently exacted, and a repetition of the offence was sometimes followed by the capital penalty. Even now, heavy fines are enforced on those destroying the trees springing up in their fields. Custom lingers long in India, and so great is the dread which has been instilled by former ferocious punishment that few will care to do any wilful injury to the State monopoly. The fallen trees suffer little from the elements, and the white ants, whose ravages on all wooden articles are so greatly feared, merely clean the logs of their bark and alburnum, and leave the scented heartwood intact. All that has to be done, then, is for the ranger to bring in enough roots and trunks to fill the local dépôt for the annual sales. There the various pieces are cut to convenient sizes, trimmed and smoothed, and the produce parcelled out in a complicated series of grades. After due adver-

FIG. 11.—SANDALWOOD TREES (*SANTALUM ALBUM*) IN SOUTHERN INDIA.

conditions offered by the native state of Mysore in South India. Here alone it thrives to the best advantage, and thus it is that this favoured State produces nine-tenths of the 2,000 tons of Sandalwood offered for sale each year. The value of the scented wood and the oil obtained from it is considerable, and the Mysore treasury is enriched to the extent of some £50,000 a year from these sources. No forest produce is more easily collected. Calculation as to the maturity of the trees to be felled is not needed, for all the year's supply is obtained from the old, dead trees, each carefully marked by the officers in charge of the range or district. The Sandalwood is a Government monopoly, and, thanks to the stringency of the laws, little or no theft or smuggling need be feared. In former times, anyone caught injuring a Sandalwood tree was liable to very severe penalties, a limb for a

tisement, traders come from all parts of India, but chiefly from Bombay and North India, and the auctions commence. These sales are of great interest, and many curious incidents are witnessed as the rival buyers emulate one another for the possession of a particular log which has taken their fancy. Sometimes two rivals will bid against one another to far above the market value of the piece, one finally relinquishing it with the exclamation, "May Allah have mercy on you over the price of that piece."

For many years past, the Mysore forest department has spent large sums of money in planting Sandal, with very indifferent success. Certain peculiarities of growth led to the theory that the Sandal requires special protecting trees, and these have been called "nurses." It has been noticed that, while the plant requires dense scrub in which to spend its youth,

it must have its head in the sun, and it has come to be recognised that the tree needs, above all, lateral shade for its lower parts. Very little attention seems to have been paid to the well-known scientific fact that the plant is a root-parasite and obtains no inconsiderable portion of

of other plants, and its suckers or haustoria were briefly described by Solms Laubach in the *Botanische Zeitung*. This simple fact of root-parasitism throws light on many of the Mysore difficulties, and the whole complicated theory of nurses and lateral shade submits to an easy

is presented for the parasitic attachment. The seed is amply provided with endosperm, which, on germination, is quickly transferred to a radish-like swelling of the hypocotyl. From the end of this swelling a long tap root is sent down, plentifully provided with side branches, on which multitudes of haustoria are developed. The seedling is able to live on its own stores of nutriment for some months, as may be readily proved by growing Sandal seed in pure sand in a greenhouse. Very interesting specimens may, in fact, be obtained with little difficulty in this way, and if the sand is interspersed with small pieces of bottle cork the haustoria lay hold of these with great avidity and sometimes attain a very fair size (fig. 15). The early efforts of the Sandal seedling seem, indeed, to be guided by little intelligence, for firm attachments are sometimes made to small bits of quartz, dead sticks or pieces of straw and other Sandal roots. From all this it may be readily believed that the parasitism of the Sandal in nature is very wide, and long lists of plants have now been prepared to whose roots the haustoria have been found firmly fixed.

During recent years a serious disease has made its appearance among the Sandal trees in

FIG. 15.—THE SANDALWOOD TREE (*SANTALUM ALBUM*).

A. Seedling. B. Root of Lantana attacked by Sandal. C. Germination of Sandalwood seed. D. Roots of A attaching themselves by haustoria to pieces of cork.

FIG. 16.—BRANCH OF *SANTALUM ALBUM* AFFECTED WITH SPIKE DISEASE.

Mysore, the leaves become more abundant, smaller and stiffer, and quickly fall off, no flowers or fruits are formed and the tree ultimately dies. At first, this disease, termed "spike" (fig. 16), from the appearance of the shoots, infected only old trees, and the attack gave rise to no apprehension, because it only made the collection of the year's wood more easy. But, later on, young trees of all stages were affected, and the whole of the Sandal growth in certain tracts was threatened with extinction. The Mysore Government has accordingly offered a large sum of money for a cure, because the natural reproduction by seed has ceased in these tracts, and in a few years there will be no large trees left. The cure is not at present forthcoming, and the cause of the disease is undetermined, so that the prospect has to be faced of the loss of this valuable source of revenue, unless this disease gradually becomes less virulent—like so many others in the ordinary course of nature—and the plantations recover. The present situation is none the less serious, for, although there are other Sandalwoods in the market, for instance, those of Malabar and Venezuela, these are produced by other species of plants, and the true and best-scented wood is only to be obtained from South India.

its nutriment from the roots of other trees. Years ago, Scott, the Curator of the Botanic Garden in Calcutta, finding it difficult to transplant Sandal trees without a very large ball of earth, discovered that its roots were attached to those

of other plants. The seedlings and young plants are much sought after by animals of all kinds, so that it is only in dense scrub that protection against their molestation is afforded, and it is just here that the necessary tangle of foreign roots

The Week's Work.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

PEACH TREES ON WALLS.—During mild weather wall-trees may be pruned and the growths retained. On no account should pruning be done during frosty weather; where it is desirable to retard the growth of the buds, the pruned wood might remain detached from the wall or wires so long as it may be thought necessary, but when the growths are replaced, care should be taken not to overcrowd them, but to allow sufficient space between each shoot to admit the laying in of the next season's growths without undue cramping.

PRUNING.—Much of the current work in this department will depend upon the state of the weather. If fine, the pruning, regulating, nailing, or tying of the shoots of wall trees may be proceeded with. Apricots, being the earliest to break into growth, should be dealt with first. The spurs on Cherry, Pear, and Plum trees should be thinned, as nothing is gained by overcrowding, and spurs are usually present in abundance on mature trees. Plump buds are frequently developed on the ends of the spurs, but the best and ripest buds are found near the bases of the spurs. The pruning and thinning of standard and other orchard fruit trees should also be taken in hand. These operations are too often neglected in the case of these trees, with the result that the crops are inferior. If orchard trees were pruned judiciously each year, there would be less heard about deficient crops, and the fruit would be of better quality. All branches that cross or crowd other shoots should be removed, in order to admit air and sunlight to the branches. Gumming and canker often result from shoots rubbing and chafing each other.

SEASONABLE WORK.—Should frosty weather prevail, stakes and other supports may be trimmed, painted, and generally made ready for use. New wall-shreds may be cut and prepared, for on no account should old ones be used again, as these are almost certain to contain insects or their eggs, and the expense of new material is trifling. Medicated shreds are the cleanest and best to use, and the additional expense is very small. Fruit walls provided with wires for training should be examined, and all defective wires made good, also any loose and misplaced eyes or strainers. See that the terminating holdfasts are securely fixed in the wall, and all new wires well painted before the trees are again trained. Wires on walls provide the cleanest and the best method of training fruit trees.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

THE GREENHOUSE.—During the winter months it is a common practice for plants from the cold greenhouse to be distributed in the various fruit houses. This system answers very well in the case of soft-wooded plants, but those of a more permanent character are best kept in the greenhouse proper. For example, such plants as Cape Heaths, New Zealand plants, and Azaleas, should not be removed from one house to another, however much such a practice might suit the grower's convenience. Cape Heaths are susceptible to attacks by mildew, and on the first appearance of this disease measures should be taken to suppress it. Apply a light dusting of sulphur as a very fine powder. In the case of New Holland plants, they are, even at this season, very subject to attacks of Red Spider, thrip, and White Scale. Red Spider and Scale may be destroyed by the insecticide recommended below, but it must be applied with great care. Thrips may be present unsuspected on plants of *Rhododendron indicum* (*Azalea indica*) and greenhouse *Rhododendrons*; directly any are detected fumigate the house. It is a good plan to give the greenhouse a thorough cleansing in winter on the lines recommended in my previous calendar on the stove. At the

same time overhaul the climbers trained to the roof. Some, including the hardier varieties of Passion Flower (*Passiflora*), Mandevilla, and similar plants that flower upon the wood of the current year may be pruned, but not such plants as *Chorizema*, *Clematis indivisa*, and *Rhynchospermum jasminoides*, as these should be allowed to flower first. Where required, apply top-dressings to plants growing in borders, and where necessary extend the rooting medium. After all is made tidy, re-arrange the plants on the stages, studiously avoiding overcrowding. Whenever the weather becomes very cold, necessitating the use of much fire-heat, close attention must be given to the watering of the plants. It is surprising what a difference careless watering makes to greenhouse plants, especially to specimens that have been long established in pots. In the case of plants of the Heath family, including *Azalea indica*, also the *Epacris*, to allow the roots to become dry weakens and spoils to a great extent the future flowering. At such times I advise a general damping down in the greenhouse to maintain sufficient atmospheric humidity. Give close attention to all plants upon shelves, and see that they do not become unduly dry. Autumn sown *Mignonette*, for instance, that is well advanced towards flowering, should never be allowed to have the soil in the pots quite dry, for the effect will be seen later in yellow leaves. I mention *Mignonette* because the best plants I ever had of this flower were grown on a shelf in a greenhouse.

INSECT PESTS.—In re-arranging the plants afterwards, look well to their condition as to insect pests. Where there is any mealy bug or scale insects, give a thorough cleansing, using a well-proved insecticide for this purpose. When, in the past, I have had to deal with bug, I have always found the Chelsea Blight Composition to be most effective, but it must not be used beyond the strength advised until experience has been gained in its use, and the contents must always be shaken before use. With soft brushes and soft sponges no harm will be done if care is exercised by the operator. In the case of thrips (both black and white) nothing is more effectual, in addition to sponging, than three fumigations with an interval of one night between each application. This remedy will also considerably check all kinds of scale insects. Where beetles and cockroaches abound, every possible means of eradication should be resorted to when a favourable opportunity occurs.

TEMPERATURES.—I am no advocate of high temperatures during the winter season, nor indeed at any season of the year so far as they are produced by excessive firing. For the stove proper a night temperature during the resting period of 60° Fahr. is quite sufficient, as an average. A fall after banking up and towards the morning of 5° will do no harm. During the day a rise of, say, 5° to 65° is ample if the weather is cold or windy. When, however, it is mild weather, 70° will be a good warmth to maintain. For the intermediate house or cool stove 5° less will suffice all round. In the greenhouse no firing should be employed beyond what is necessary to maintain the atmospheric temperature at night at 40°, with a natural rise during the day. To conserve all fuel at this season, should be the aim, for there will be plenty of need for fuel in the spring. During mild weather keep all cool houses ventilated a little at night.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westboult, Gloucestershire.

TEMPERATURES.—One of the chief difficulties with which the cultivator has to contend in winter is that due to the changeableness of the climate. The changes occur so suddenly that there is but little time to prepare for them, and extreme watchfulness is necessary, in order to prevent the temperatures of the houses fluctuating to an extent that is harmful to the plants. There should be provided a sufficient supply of water pipes in every Orchid-house to heat the houses adequately without having to overheat the pipes on any occasion. If the pipes are overheated a condition of dryness is brought about which is at once obvious to a cultivator on entering the house, and plants subjected to such dryness arising from excessive fire-heat are rendered more liable to attacks from certain parasites, whilst the foliage frequently

assumes an appearance of yellowness, which it is impossible afterwards to obliterate. There is little doubt but that in most Orchid-houses the temperatures maintained are higher than are necessary. The winter temperatures of the various departments should be kept somewhat as follows:—**Stove or East Indian-house:** (day) 68° to 74°, (night) 60° to 65°. **Cattleya-house:** (day) 60° to 65°, (night) 55° to 60°. **Intermediate-house:** (day) 58° to 62°, (night) 52° to 56°. **Cool or Odontoglossum-house:** (day) 54° to 58°, (night) 50° to 54°. The higher or lower temperatures given should rule according to the condition of the weather out-of-doors. During severe weather no harm will occur if the temperatures should fall a few degrees lower than even the minimums given, and, if the day temperatures should rise 10° above the higher figures I have stated, and the extra heat is obtained from sunshine, this will greatly benefit the plants.

LYCASTE SKINNERI.—Those who possess even a moderate batch of *Lycaste Skinneri* may reasonably expect to have flowers from now until April or May. The earliest plants may be encouraged to open their blooms a little earlier by placing them in a slightly higher temperature, when the flower-scapes are in course of development. As regards temperature at other times, I think a cool intermediate one is the best for this species. At the present season the plants should be kept moderately dry at the roots, but it will not be safe to allow them to suffer from drought for any appreciable period.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

CUCUMBERS.—Make provision at once for the raising of seedling Cucumbers for early spring planting. Sow the seeds in small, clean pots, and place the pots on a gentle hot-bed in a warm structure which has been thoroughly cleaned for the purpose. The soil should consist of finely-sifted loam and leaf-mould in equal parts. When the seedlings have made their first rough leaf, they should be carefully potted into 3-inch pots, and replunged in the hot-bed, raising them as near to the glass as practicable. Plants which are now furnishing supplies should be given every encouragement. Top-dress the bed as often as the young roots are seen on the surface, applying only sufficient soil at one time to cover the roots, and removing all decaying leaves and deformed fruits. Only sufficient fruits to provide the daily supply should be allowed to develop. The atmosphere should be kept constantly moist.

BROAD BEANS.—A sowing of Broad Beans may be made as soon as the soil is in a suitable condition. Land which has been trenched and manured some time previous to sowing is the most suitable for this crop. Drills should be drawn 3 feet apart and 3 inches deep, allowing 6 inches between the seeds. Improved Long Pod and Broad Windsor are reliable varieties, both being of vigorous habit and the Beans of good quality.

POTATOS IN HEATED PITS.—Careful attention must be given to the earliest plantation in ventilating and earthing up. Fresh air should be admitted when the weather is favourable, but cold draughts must be prevented. Earth up the plants as soon as they are large enough, so that the roots may not be disturbed after the tubers have commenced to form. Successional plantations should be made fortnightly, thus keeping up a continuous supply. Assuming that sets for this purpose have made some growth, they should be carefully planted in rows 18 inches apart and 9 inches from plant to plant, nothing being gained by planting too many sets in one pit. Those who are unable to devote a pit to Potato culture may grow a few plants in pots, to provide an occasional dish through the spring. If sets of some good early variety are potted up now, tubers should be ready for the table early in April. Eight-inch pots may be made half full of good rich soil, and two sets placed in each. If 10-inch pots are employed, four sets may be allowed, the pots being well crocked. Very little water will be necessary if the soil is in a good condition at the time of potting, but when the plants are a few inches high a good watering may be given, and the pots filled to within 1 inch of the top with loam and leaf-mould in equal parts. A temperature of 50° will be suitable, and fresh air should be admitted.

THE FLOWER GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of Haddington, Tynninghame, East Lothian.

PRUNING FLOWERING SHRUBS.—Several kinds of flowering shrubs are ready for their annual pruning. Of such are Spiræas of the callosa type, which should have all the weak growths removed and the strong, young shoots cut back to two or three buds from the base; Polygonum baldschuanicum, which with many fails to flower, although it blooms from June to October here. At this season the plants are spur-pruned, with the exception of those shoots left for extension which are shortened a little. Weigelas need the older growths removed, whilst the stronger-growing Deutzias require similar pruning. All the hardy Roses which generally only require thinning of the shoots may also be attended to at once. These include the Scotch Persian, rugosa, Pennsylvania, alpina, Ayrshires, and Félicité-Perpetué. Damask, Gallica and Provence Roses, though usually not pruned till the spring, may also be slightly pruned now and the beds they occupy made neat. I observe that Snowdrops are already peeping above the ground, and signs of growth are apparent in the case of other early flowers. Where these are growing under trees it helps them considerably to dress them with a layer $\frac{1}{2}$ inch thick of a rich compost after it has been passed through a $\frac{1}{2}$ -inch sieve. The first heavy rain will smooth down inequalities, and the flowers will not be long in showing that they are benefiting from the dressing. In the mixed flower borders, which were dug in October, the clods should be broken and the surface smoothed, while the portions occupied by early bulbs should be dressed on the surface with material of the same kind as that above-mentioned. Large groups of Phloxes, Pæonies, Astilbe grandis, A. Davidii, and Lemoine's hybrids that were not manured in the autumn should be attended to at once. Well-decayed cow manure is the best material for the purpose; an inch or two of the surface soil should be first removed from above the roots, the manure being then applied evenly and the surface soil returned. Fresh soil would be preferable, but it is really the manure that is essential. Protective material, such as shoots of Furze, should be kept on beds of seedling Eremuri. Directly the blades appear above the ground remove the weeds, stir the surface lightly if it is dry enough to work, and whether or no apply a slight dressing of soil. Old soil from the surface of a Vine border is excellent for this purpose, and a slight sprinkling of soot has its advantages.

SEED-SOWING.—Seeds should now be sown of certain bedding plants, such as fibrous and tuberous-rooted Begonias, Verbena venosa, Hollyhocks, Gilia coronopifolia, Pentstemons, including such species as P. speciosus and P. heterophyllus, Delphiniums for autumn flowering, and various sub-tropical plants. All these seeds need a stove temperature to cause them to germinate quickly, and the seedlings should be pricked out directly they are large enough to be handled. Sweet Peas may be sown as soon as convenient after this date. Several English gardeners tell me that I allow Sweet Peas too much space; therefore cultivators must determine for themselves how thinly their plants shall be cultivated. In my own case, I allow them 2 feet apart. My practice is to sow one seed in a small 3-inch pot, cover the pots with boards to keep mice away until the seeds have germinated, and directly they have germinated in a warm pit they are removed to a cooler structure.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

EARLY PEACHES.—Trees in houses that were closed early for providing the first crop of fruit will now be fast approaching the flowering period. Until that stage is reached, a moist atmosphere may be maintained by damping the surfaces in the house, especially those near to the water-pipes. This damping should be done after breakfast and again early in the afternoon. The trees may also be sprayed over with tepid water in the morning if it promises to be a fair day, and in the afternoon if it is likely that the trees will become dry by nightfall. Admit air whenever the outside conditions are favourable, if only for a short period, but close the ven-

tilators again early in the afternoon. Only sufficient fire-heat should be used to maintain an atmospheric temperature of 50° at night, and, in the event of cold, windy nights, rather let the heat fall a few degrees than heat the pipes excessively. Before the flowers commence to expand, fumigate the house slightly with the XL. All vaporising compound to destroy any aphides that may be present. Ants are frequently seen to be busy on trees in flower, and as they damage the flowers, means should be taken to prevent their gaining access to the trees. Cotton wool, tied at the base, acts as a good deterrent, but this material must be kept dry, or it will be useless for the purpose. During the flowering period a slight increase in the temperature is desirable, and the surroundings must be kept drier, withholding the use of the syringe and giving as much air to the house as circumstances will allow. For the early-forced trees, pollination of the flowers should be artificially carried out by touching the flowers very lightly at midday with a rabbit's tail tied to a light bamboo cane or stick. This tail, when not in use, should be kept in a perfectly dry condition. During periods of sunshine give the trellis a sharp tap; this will cause the pollen to disperse; for later trees this method of distribution will be quite sufficient. When the flowers are set, resume the damping of the houses and damp the trees again lightly, but do not provide too much moisture until the fruits can be observed plainly.

POT VINES.—These are now growing freely, and the stages of growth will vary according to the time when they were started. Disbudding should be carried out at intervals until one shoot is left to each spur, choosing the shoot which has the most promising inflorescence. Stop the shoots when they have developed two leaves beyond the flower, and unless these come into contact with the glass do not attempt to pull them down for the present, as the fertilisation of the flowers will be facilitated by their nearness to the light. Maintain the atmospheric temperature at night at about 58° or 60°, and damp the ground surface in the house as often as is necessary to keep the atmosphere in a humid condition. In the mornings, when the temperature begins to rise, air may be very carefully admitted, gradually increasing the amount according to the state of the weather; but close the ventilators again early in the afternoon, whilst the sun is still shining on the house. Watering must be done very carefully, and the growths may be syringed with tepid water until the flowering period is reached, when spraying should be discontinued. Pollinate the flowers artificially, as advised for Peaches. When the setting of the flowers is complete, any bunches that have failed to set well should be removed, and any others that may be necessary to prevent overcropping. The roots will then be very active, and occasional applications of diluted liquid manure water may be given, or a sprinkling of some approved artificial manure scattered on the surface of the soil. Keep the evaporation troughs filled with water and damp the surfaces with liquid-manure late in the afternoon.

THE FRENCH GARDEN.

By P. AQUARIAS.

THE HOT-BEDS.—Most growers have now started the hot-beds. From these are obtained the most remunerative crops and also decayed manure that is necessary for the other parts of the garden. The amount of manure required varies between 6 to 8 tons for every bed of 15 lights, and one part old manure should be used to three parts of fresh manure. The height of the beds, especially when the Lettuce plants grown under the cloches are strong and healthy, need not exceed 10 inches when trodden down. The bottom heat should not exceed 50° to 55°. The two sorts of manure are mixed together on the spot, and the bed built straight and level to facilitate the placing of the frames in their proper positions. A path 10 inches wide between each row of frames is sufficient, and, in many places, 9 inches may suffice. Objections are sometimes raised to the narrowness of the paths as being awkward for working, yet, by their use, the wind has no great power, and lining is done very economically in narrow paths, which workmen soon get accustomed to. Seeds of Early French Breakfast Radish and Early Parisian Carrot are sown immediately after the bed is completed, before proceeding with the next row.

The seeds are covered with fine soil that has been stored under cover for a few weeks, using about one barrow-load for each frame. The soil is made level, pressed down evenly, and six rows are marked out for planting the Lettuces before placing on the lights. Fermentation will be active three or four days after the bed has been formed, according to the condition of the weather and the state of the manure. Plants of Lettuce "Little Gott" are then set seven in each row, or 42 in a light; but the cotyledons and any decayed leaves are first removed. Sometimes when the bed contains too much hot manure, Radishes germinate within 60 hours, and the seedlings grow spindly. In this case, ventilation should be given for one or two hours daily. The planting of the Lettuces is deferred for a few days, until the temperature of the bed is normal. The lights are only covered at night-time in case of frost, and some growers only spread mats over them in very severe weather, especially when the Lettuces grow in a bunch, which is a certain proof of excessive bottom heat. As unfavourable weather may at any time prevent the work being carried out, it is highly important that the grower should avail himself of every fine day for the making of the beds. In establishments where the lights do not exceed 150 in number, one bed may be made each day; but where this number is exceeded, not less than two beds should be laid down daily, so as to have them all finished by the end of January. Our frames intended for "cold work" are ready for immediate planting. Seeds of Radishes are inserted and raked in. The soil is pressed down, and five rows are marked out for planting Lettuce "White Passion," and six rows for the variety "Little Gott." When the soil is wet, a little ventilation for an hour in fine weather is beneficial.

THE APIARY.

By CHLOEUS.

SEASONABLE WORK.—It will be advisable to raise the roof of every hive to ascertain if the quilts have become wet from the continuous rains; wet covers must be removed at once and replaced by dry ones. At the same time, it will be wise to add a cake of candy if the food stores are considered to be deficient, for during such weather as has been experienced lately bees consume an extra quantity of food.

HOW TO MAKE CANDY.—One of the simplest methods of making candy is to warm some honey until it is in a thoroughly liquid condition, and afterwards mix some fine loaf sugar with it, until the whole assumes the consistency of dough. Then, when it will apparently dissolve no more sugar, put it aside for a few days, and, if any honey is found to be unabsorbed, add more sugar. When honey cannot be secured, soft candy must be made of sugar. For this operation a preserving pan is best, but a good substitute is an enamelled pan. The object of the maker must be to secure a soft candy of the consistency of butter. Do not begin the work until the fire is quite clear and bright. Place one quart of water in the pan and bring it to the boil, stir in 5 lbs. cane sugar crystals, until the whole is dissolved, and skim off all scum that rises. When the mixture is quite clear let it stand unstirred for about 20 minutes, allowing it to boil the whole time as fast as possible. It will then probably be cooked sufficiently, but to test it if it is done take a bowl of cold water and into this dip the forefinger of the right hand and then quickly dip the wet finger into the boiling sugar. Remove the finger, dip it again into the cold water, and if the adhering sugar may be rolled into a smooth ball it is ready to remove from the fire. If the ball cannot be formed, the pan must be returned to the fire and the syrup boiled for a few seconds longer. When the boiling is complete, pour the liquid into a shallow vessel and allow it to cool without stirring, until it will not scald the finger. Then stir until it becomes white and sets. In order to place the syrup in moulds, stand the vessel over boiling water on the fire until all the sugar is melted and nearly boiling; run the syrup in moulds or sections resting on paper for a bottom.

LEAKY ROOFS.—The best plan is to cover the roof with a sheet of zinc, leaving one sheet the metal to turn over the edges to secure a tight nailing. Failing zinc, cover the roof with well-stretched calico, and afterwards apply about four coats of paint.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions, illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JANUARY 16—
Roy. Hort. Soc. Exam. of Public Park Employés at 10 a.m.

TUESDAY, JANUARY 17—
Roy. Hort. Soc. Coms. meet. (Lecture at 3 p.m. by Mr. H. C. Long, on "Weeds and Weed Seedlings")
Scottish Hort. Assoc. Ann. Meet.

WEDNESDAY, JANUARY 18—
Roy. Meteorological Soc. Ann. Meet. at Inst. of Civil Engineers 7.30 p.m. Nat. Sweet Pea Soc. Special General Meet. at Hotel Windsor 2.30 p.m. Forest Hill Chrys. Soc. meet. (Lecture by Mr. R. B. Leach, on "Chrysanthemums.")

THURSDAY, JANUARY 19—
Gard. Roy. Benev. Inst. Ann. Meet. at Simpson's Restaurant, Strand, 2.30 p.m. Friendly supper at 6.0 p.m. Linnean Soc. meet.

SATURDAY, JANUARY 21—
Brit. Gard. Assoc. Meet. at Birmingham. Soc. Française d'Hort. de Londres Ann. Dinner.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—38.5°.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, January 11 (6 P.M.): Max. 45°; Min. 34°.
Gardens' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 12 (10 A.M.): Bar. 29.6; Temp. 42°; Weather—Dull.

PROVINCES.—Wednesday, January 11: Max. 45° Ireland S.W.; Min. 32° Scotland N.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Herbaceous Plants, Lilies, Hardy Bulbs and Plants, at 12; Roses, Fruit Trees, Azaleas, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Border and Alpine Plants, Hardy Bulbs, Lilies, &c., at 12; Roses, at 1.30; Japanese Lilioms, at 2.30; Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

1911.

The almanac, which we present with this issue, affords ample evidence that the year 1911 is not likely to be less well supplied with events of horticultural interest than its predecessors.

This much is clear, although there will not be the number of international exhibitions that took place last year. In this respect there will be a period in which the international feeling will be expressed in the preparations made in this and other countries for our own international exhibition and congress of May, 1912. But there is at least one international fixture of importance for the present year, namely, the conference on Genetics to be held in Paris in September. This is the natural successor to the conference held in London in 1906, and it may be confidently anticipated that our colleagues in France will do all that is possible to make the event one that will live in the memories of those who may be privileged to be present. We take this opportunity to appeal to British horticulturists to second these efforts by rendering what assistance it is within their power to give.

In London, the Royal Horticultural Society will hold its fortnightly exhibitions and the

Temple Flower Show as usual. A competitive bulb display will take place in March, an exhibition of fruits in the autumn, a vegetable competition in September, and an exhibition of Colonial fruits in November. The greatest novelty will be the summer show, which, since the Holland House grounds are no longer available for this exhibition, will take place at Olympia, in close proximity to the former site. The spacious Olympia building may be expected to provide ample room for a very large show, and, in the event of wet weather, it will have an advantage over tents, which may be some compensation for the obvious sacrifices in other directions imposed by the change of site.

The special floral societies have each one or more exhibitions already arranged. The shows of the National Rose, Sweet Pea, Dahlia, Chrysanthemum, Carnation, and kindred societies will be provided for with increased liberality; therefore, the outlook for 1911 is very favourable. The National Vegetable Society will hold its second exhibition at the end of August. Turning to the provinces, great exhibitions will take place at Shrewsbury, Edinburgh, York, Wolverhampton, Birmingham, Manchester, Leamington, Southampton, and other places. The promoters of the Northern Fruit Show and Congress at Hexham last year, encouraged by their success, hope to hold a similar display this year at Carlisle, probably under the auspices of the newly-formed Northern Horticultural Society. This society, however, has not yet had sufficient time to issue its programme, which may be found eventually to contain a provision for an exhibition at Leeds. The National Chrysanthemum Society is also unable at the time of going to press to afford information of the dates of its exhibitions for the present year.

Spring flower shows, consisting mainly of Daffodils and other bulbous subjects have increased in numbers in recent years, and fixtures are already arranged at Birmingham, Torquay, Paisley, Truro, Plymouth, Ipswich, and other centres. None can prophesy what are the weather prospects for 1911, but we may express the hope that the weather may take a turn for the better in the coming summer.

**Britain
as a
Market for
French
Fruit.**

The problem of the distribution of the products of industry is one to which more and more attention is being directed. Thus we find, almost daily, special reports being issued, pointing out new ways to reach fresh markets. Among the latest of these reports is one by Mr. Léon Loiseau on "The English fruit-market and co-operation among producers for purposes of distribution," a summary of which is published in the *Journal* of the Horticultural Society of France for November, 1910. The flattering attention which this country receives from such special commissioners as Mr. L. Loiseau, although it cannot be expected to rejoice the heart of the home producer, cannot be ignored, and it may at least be turned to some advantage if our home growers can discover from the reports issued points which may help themselves to distribute their produce with more advantage to themselves.

To give but one example of the thoroughness with which Mr. L. Loiseau has done his

work: after pointing out the disastrous losses suffered in the Paris market by French growers during periods of glut, and after indicating how small a proportion of fruit imported into Britain comes from France—less than one-sixth—he reviews the carriage rates, publishes maps illustrating the density of population in different parts of Great Britain, and even goes into minute details as to the mode of packing most favoured in this country. Mr. Loiseau urges co-operation, and points to the success of various French co-operative distributing companies.

Perhaps we may be allowed to say that within our own experience the French grower might do more than he does for his own markets. We ourselves year by year suffer, in a part of France that shall be nameless, from a veritable fruit famine. In early August we have searched throughout a fairly large French town for Plums and failed to find ripe ones; whereas, as we knew, the country round was rich with fruit. If the French growers would combine to develop yet further their own provincial markets none would take it amiss, although we hasten to add that, so long as we must get fruit not grown in this country, we would as soon get the Pears, Apricots, Peaches and Figs grown in the "sunny fields" of France as those grown anywhere else.

**Gooseberry-
mildew in
Cambridge-
shire.**

In spite of the efforts which have been made to check the spread of the American Gooseberry-mildew, this disease was more widespread in this county during 1910 than hitherto. The climatic conditions of the summer of 1910 were particularly favourable to the propagation of the disease, and this circumstance should be taken into account when considering the more frequent occurrence of this mildew during the past season. In 1909, the number of infected gardens was 179, which is about the same number as in 1908, but during 1910 these figures increased to 372. A large number of the fresh cases this year have occurred in allotment gardens where the plots are contiguous with one another. Although these allotments must be scheduled separately on account of occupation by different growers, it is clear that the outbreak of disease in the plots must be often one and the same. If one of the allotments is diseased, the probability is that many such plots will become affected. As so many of the newly-infected gardens are small, the actual acreage of bush fruit scheduled during 1910, as compared with that of the previous year, has not increased as much as the figures given above might appear to indicate.

The intensity of the disease has been only slightly greater this year than before, and in the large majority of scheduled plantations the mildew is present only to a small extent. Winter pruning of affected shoots has undoubtedly checked the progress of the disease in the spring, with the consequence that in Cambridgeshire the fruit has remained clean in practically every garden. In only two or three cases has there been any appreciable number of berries affected. By a continuation of this practice it should be possible to prevent this pest from doing serious damage to the fruit.

It is now known that one of the chief dangers of the recurrence of the disease from one season to another lies in the falling of the resting bodies (perithecia) of the mildew on the soil or on lower twigs during the winter, and the subsequent reinfection from these sources during the spring. These winter spore-cases fall the more readily the longer they have been produced. Consequently, the earlier in the autumn and winter the pruning can be effected, the better, though, for obvious reasons, no cutting should be commenced while there is still risk of the bushes putting forth new shoots.

Towards the latter part of the summer of 1910 a few cases of disease were observed in the Cambridge district, in which the resting bodies of the fungus had been formed on the leaves. Generally speaking, the perithecia of the American Gooseberry-mildew are produced only on the shoots, while the perithecia of the comparatively harmless European Gooseberry-mildew are developed on the leaves. It is clear that if the resting bodies of the American mildew come to be developed at all frequently on the leaves the difficulty of keeping the disease in check will be increased.

So far, there has been no reason to complain of the way in which growers in Cambridgeshire have performed the pruning operations. It seems to be generally recognised that winter pruning is the chief means of minimising the damage done by this pest. One noticeable effect of compulsory pruning has been the cleaning up of many plantations which had been badly neglected previously.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will take place on Tuesday, January 17. In the afternoon a lecture on "Weeds and Weed Seedlings" will be given by Mr. H. C. LONG.

HORTICULTURAL CLUB.—The next house dinner of the club will take place on Tuesday, the 17th inst., at 6 p.m., at the Hotel Windsor. The Rev. Canon HORSLEY, J.P., will deliver a lecture on "The Scenery and People of the Bernese Oberland," including Swiss plants illustrated by lantern slides.

NATIONAL SWEET PEA SOCIETY.—A special general meeting of the members will be held in the North Room, Hotel Windsor, Victoria Street, Westminster, at 2.30 p.m., on Wednesday, January 18, to consider the following proposals regarding the constitution of the Floral Committee:—The General Committee, strongly objecting to the definition of an amateur as stated in the instruction carried at the annual general meeting, i.e., "That no member on the amateur side of the Floral Committee be in any way connected with the selling of Sweet Peas," proposes that such instruction be rescinded. And further proposes that the Society shall define an amateur in accordance with the regulations of the Royal Horticultural Society.

ROYAL METEOROLOGICAL SOCIETY.—A meeting of this Society will be held at the Institution of Civil Engineers, Westminster, on Wednesday, 18th inst., at 7.30 p.m. The annual general meeting will be held at 7.45 p.m. The business will include (1) report of the Council for 1910; (2) election of the Council for 1911; (3) address on "The Present Position of British Climatology," by HENRY MELLISH, F.R.G.S., President.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The 71st annual general meeting of the members and subscribers of this institution will be held at "Simpson's," 101, Strand, London, on Thursday, January 19, at 2.45 p.m., for the purpose of receiving the report of the committee and the accounts of the institution (as audited) for the year 1910; electing officers for the year 1911; and for the election of 20 annuitants on the funds. The chair will be taken by HARRY J. VEITCH, Esq., F.L.S., V.M.H., treasurer and chairman of committee, at 2.45 o'clock. The poll will open at 3 o'clock and close at 4 o'clock precisely, after which hour no voting papers can be received. All voting papers were issued on December 29 last. Subscribers who have not received copies should communicate with the Secretary, Mr. GEORGE J. INGRAM, at the offices, 92, Victoria Street, Westminster, S.W. The annual friendly supper will be held also at Simpson's on the same day at 6 p.m., when JOSEPH ROCHFORD, Esq. (member of committee) will preside.

—The 72nd anniversary festival dinner in aid of the funds of this institution will take place on Tuesday, May 23 next, the first day of the Temple Flower Show, when Alderman SIR MARTIN SAMUEL, Bart., will preside. The dinner will be held by permission of the Worshipful Company of Grocers in the Grocer's Hall, Princes Street, City.

APIOS TUBEROSA.—Owing to a misprint in last week's issue, the name of this plant, described by Mr. LYCHE, was spelt "Apice."

THE RAINFALL OF 1910.—Many gardeners keep meteorological records, and, following their practice of several years past, some have furnished us with notes concerning the year's rainfall.

Writing from Hill House gardens, Harrow Weald, Mr. T. HUNTER states that the total fall in his district for the year amounted to 27.92 inches, or 2.34 inches more than the average. September was the driest month, the total fall being .52 inch only, this being the smallest amount recorded since 1890. December proved the wettest month, with a fall of 3.82 inches, there being 29 days in that month on which rain was recorded.

At Davenham Gardens, Malvern, Mr. C. A. BAYFORD recorded a total rainfall for the year of 32.89 inches, there being 195 wet days. The wettest month of the year was August, which included 24 wet days. The greatest rainfall recorded in 24 hours occurred on August 28, the amount being 1.65 inch.

From statistics compiled by Mr. H. WILSON in the gardens at Coleorton Hall, Ashby-de-la-Zouch, December proved much the wettest month. The heaviest fall in the district occurred on December 1, a total amount of 1.53 inch being registered. The amount for the year, 32.01 inches, proved the largest recorded during the past seven years. Rain fell on 190 days, and February, August, November, and December had all more than 20 wet days.

Mr. JOHN EDWARDS, Sylfaen Gardens, Wlshpool, states that rain fell intermittently from 4 a.m. on December 1 till 8 a.m. on December 3, and during this period 2.23 inches was registered. Rain continued to fall in a measurable quantity during the 16 days following, to a total depth of 6.37 inches. Counting 23 days of November, there were 49 wet days out of 61 in two months, giving 12.20 inches of rain. From December 10 to December 18, the barometer reading was very low; on December 10 it was 27.50°. On December 27 several plants were in flower, including Roses in variety, Primroses, Daphne Mezereum, whilst a Cob Nut had female flowers expanded.

The rainfall for 1910 at Llanishen, writes Mr. HAROLD EVANS, amounted to 10 inches more

than the average; 5.83 inches of this excess was registered during the last two months of the year. Rain fell on 48 days during November and December. The total rainfall for the year was 49.37 inches, compared with 42.96 inches in 1909. January, February, June, August, October, November, and December were all wet months. During February, rain fell on 27 days.

At Leonardslee, Sussex, Mr. W. A. COOK, the gardener, registered 35.99 inches during the past year. There were 130 days on which rain fell, the wettest month being November, with 14 rainy days. The driest month was September, the fall only amounting to .30 inch, recorded on four days. During February, a measurable amount of moisture fell on each of 22 days. The greatest fall occurred on November 13, and amounted to 1.13 inch.

Mr. J. B. ALLAN, Osberton Gardens, Work-sop, states that the heaviest rainfall occurred on October 11, when 1.45 inch of rain was recorded. The wettest month was August, when 3.64 inches fell, and the driest September, with only .31 inch. Rain fell on 181 days. The total rainfall for the year at Osberton amounted to 25.03 inches. The hottest day was June 19, when the thermometer registered 86° in the shade, and the coldest, January 27, with 24° of frost.

We are informed by Mr. G. BENTLEY, Shugborough Gardens, Stafford, that the total year's rainfall in those gardens was 34.91 inches. The wettest month was November, with 5.74 inches of rain, and the greatest fall in 24 hours occurred on August 28, the amount being 1.89 inch.

Writing from Broadloaks Gardens, West Byfleet, Surrey, Mr. J. B. LOWE gives 26.36 inches as the total rainfall for the year. Rain fell on 139 days, the wettest month being December, when 4.17 inches of rain fell on 17 days. The driest month was September. The heaviest rainfall occurred on October 11, when 1.10 inch was registered.

THE FALSE TINDER FUNGUS ON FRUIT TREES.—Of the bracket fungi which affect fruit trees in this country, the species known popularly as the False Tinder fungus (*Pomes igniarius*) is the most common. In Cambridgeshire this fungus is frequently seen on Plum and Greengage trees, particularly in places where pruning has been badly done or the plantation has been neglected in other respects. Trees suffer most from this disease as they approach maturity, young trees being only rarely affected. This fungus attacks Apple trees also, and is fairly common on other deciduous trees, such as the Beech and Oak. It is a wound parasite, which means that the spores can only cause infection of a tree when they germinate upon a wounded surface. Thus infection generally begins in a single branch, from which the mycelium or spawn travels into other parts of the tree. The mycelium has a characteristic effect upon a diseased branch. At an early stage in the attack the central part of the wood becomes deep brown in colour, and later on undergoes disorganisation. The fruit-bodies of the fungus, which usually occur on the lower side of diseased branches, are at first hemispherical, but afterwards become hoof-shaped. The fructifications are extremely hard from the commencement of development, this character making the species unsuitable for the making of tinder and such objects as those for which the true tinder fungus (*Pomes fomentarius*) has been used in the past. When orchards are being looked over in winter, branches bearing the fructifications of the fungus should be cut away and burnt, care being taken to cut back beyond the limit of the discoloured wood. Where, in the course of pruning, it is necessary to remove large branches from the trees, the cut surfaces should be covered with a coating of gas tar, in order to prevent infection by parasitic fungi.

FLOWERS IN SEASON.—About Christmas time each year we are asked by correspondents to identify flower-spikes of *Ornithogalum lacteum*. They are usually received from friends in South Africa, who are acquainted with the longevity of the cut blossoms. Accompanying some spikes sent by Mr. D. R. DIXON, Hagley Hall Gardens, Stourbridge, was the following letter: "I am sending for your inspection the enclosed flowers. They were sent from Johannesburg, and arrived about a week before Christmas. The blossoms were then placed in a large bowl of water and soaked thoroughly for several days, when they commenced to open. On Christmas Eve they were arranged in glass receptacles on the dinner-table. It was interesting to watch them open little by little in the warm room. They remained on the table until January 3, appearing more beautiful each day. I am keeping some of them to see how long they will last in a good condition. You will notice one flower-spike is still in the bud stage; they were all in that condition when they were sent." Mr. J. FERRINGTON sends from Brynbella, St. Asaph, N.W., sprays of *Azara integrifolia* covered with masses of blooms, and *Daphne Dauphine*, an evergreen variety, having numerous purple, sweet-scented blooms. Mr. FERRINGTON states that the following plants are in flower in the gardens at Brynbella:—Almond, *Erica arborea*, *Lonicera Standishii*, *Cyclamen Coum.* and *Iris stylosa*.

NORTH OF ENGLAND HORTICULTURAL SOCIETY.—The formal inauguration of this Society took place on the 6th inst., at Leeds, at a meeting presided over by Mr. J. HASTINGS DUNCAN, M.P. A large and representative company assembled in the Lord Mayor's rooms. The chairman stated that it was their intention to become affiliated with the Royal Horticultural Society, and their rules had been framed more or less in accordance with those of that Society. A resolution adopting the establishment of the North of England Horticultural Society was carried. Mr. R. B. KER remarked that there was ample scope for the new society. The rules drawn up by the provisional committee were adopted, and scientific, fruit and vegetable, and floral committees were appointed, with power to add to their numbers. The following were appointed members of the council:—Messrs. R. RAY APPLETON, Major J. W. DENT, REGINALD FARRER, CLAUDE LEATHAM, T. G. HODGSON, G. W. JESSOP, HASTINGS WHEELER, A. R. CROSSLEY, R. B. KER, and W. MATHIESON. The Rev. J. BERNARD HALL was appointed secretary, and his abilities as an organiser and administrator were referred to by several speakers.

MR. THOMAS CHALLIS, V.M.H.—Congratulations are offered to Mr. CHALLIS on the completion of 50 years' service as gardener at Wilton House, Salisbury. Mr. CHALLIS comes of an old gardening stock. His grandfather was head gardener at Cheveley Park, near Newmarket, and he was succeeded there by Mr. CHALLIS's brother. Mr. THOMAS CHALLIS served his apprenticeship under his father, who was gardener to the Duke of Rutland, at Belvoir Castle. From Belvoir he went to the Duke of Sutherland's estate at Trentham, Staffordshire, and half-a-century ago he accepted the position he still holds at Wilton Park. Besides holding the Victoria Medal of Honour, Mr. CHALLIS is a Veitch Memorial Medallist. For 43 years he has been connected with the Bath Horticultural Society, and in 1910 the members presented him with a silver inkstand and an illuminated address. On the 2nd inst., he was presented with a gold watch chain, with a locket attached, containing portraits of himself and Mrs. CHALLIS, and the following in-

scription: "To T. CHALLIS, V.M.H., on completing 50 years at Wilton Park; from his friends and assistants. January, 1911."

A FORESTRY ASSOCIATION.—According to *The Times*, an organisation of landowners and others, to be known as the English Forestry Association, is now in process of formation. The notice convening the first meeting is issued by Mr. M. C. DUCHESNE. The concluding paragraph of the notice of meeting is as follows:—"We are particularly anxious for the association to be in a position to ascertain where supplies of English timber—particularly Oak and Ash—of good quality can be obtained. Would you kindly let me have some idea of the supply of timber ripe for cutting that you would be prepared to sell, provided, of course, that you obtained a really satisfactory price for it?" Lord CLINTON will preside at the meeting at the Surveyors' Institution, on Thursday, the 19th inst., when a resolution to form the association, and the election of president, council and officers will be brought forward.

FLORISTS' FLOWERS.

CHRYSANTHEMUMS.

MR. NORMAN DAVIS, whose exhibits at the Chrysanthemum shows are always important features, sent me recently a box containing specimens of about two dozen of the best varieties of market Chrysanthemums. Some of the older sorts still hold their own. Western King for example, a pure white flower of good substance, which, although not one of the largest, is one of the most useful. Felton's Favourite is another useful white decorative Chrysanthemum of medium size with drooping florets and a well-filled centre. It is a favourite with most florists, being known by some as "Framfield Seedling." The following varieties may be recommended:—David Ingamells, a large incurved Japanese variety of deep golden-yellow colour. W. W. Moir, also a Japanese variety, with large, pure white blooms. Geo. Hemming.—A large Japanese variety of a rich crimson colour with a magenta shade and silvery-grey reverse. Mary Poulton.—The long florets are a silvery-white, with a blush tint. It makes a fine exhibition variety of the Japanese section. Old Cullingfordii.—This variety is apt to vary greatly, but the blooms received were of the richest colour. Violet Lady Beaumont.—This also was of fine colour, and the florets possessed good substance. John Shrimpton.—A fine crimson Chrysanthemum of medium size; one of the most useful sorts for market purposes. Lady Hanham.—This remains a favourite, and is good either grown naturally or disbudded; the colour varies, but Mr. Davis has it in its best form. Rayonante.—Another favourite with many, but not quite an every-day market sort.

Among single Chrysanthemums were some very pretty varieties. Of these, the following may be mentioned:—Little Dorrit.—Pure white, with a clear yellow disc of medium size. Mensa (syn. Queen of Earlies).—A large, pure white flower developed on a good, stout stem. Swinburne.—White, with blush tint; a dwarf-habited variety. Pictor.—Pink, with lighter shading at the base of the florets. Burns.—A deep yellow bloom of good substance. Tomyson.—An improvement on Mary Anderson. Shelley.—White at the base of the florets, with a suffusion of lavender. Wordsworth.—A deep mauve flower with a light shade at the base of the florets. Leo.—Chestnut red, with a slight shading of yellow around the disc. *A. Hemslay.*

NOVELTIES OF 1910.

(Continued from p. 2.)

CONTINUING our remarks upon the novelties exhibited during 1910, we may now turn our attention from the Orchids to the new species and numerous varieties of other plants that have gained distinctions at the R.H.S. and other exhibitions.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nurseries, Chelsea, have a good show of certificated plants. Amongst the most interesting are the new Chinese shrubs, which are now beginning to show their character, including a fine set of *Rhododendrons* of compact habit, such as the primrose-yellow *R. primum*, for which an Award of Merit was obtained on March 22. At later meetings the merits of *Viburnum Henryi*, *Ligustrum Henryi*, *Hydrangea hortensis* 'Ornament,' and *Primula Maximowiczii* collected in Northern China at an altitude of 9,000 feet, were acknowledged by the presentation of suitable awards. In the class of decorative plants, the firm have secured awards for *Erlangea tomentosa* (a white, fragrant flower for warm-greenhouse culture), the splendid hybrid *Nepenthes*, *N. nobilis*; *Macleania insignis* (with tubular, red flowers), *Kalanchoe kewensis*, *Pelargonium* "Snow Queen," and *Fuchsia Sylvia*, while in the matter of plants for the seed list, their charming dwarf strain of *Schizanthus*, their decorative *Cineraria* "Feltham Beauty," *Clarkia* "Brilliant," and others have also received commendatory awards.

Lieut.-Col. SIR GEORGE L. HOLFORD, K.C.V.O. (gr. Mr. Chapman), has contributed fine displays of *Hippeastrums* (*Amaryllis*). In his varieties, *Calypso*, *Cardinal Wolsey*, and *Gereant* may be seen the highest qualities which these plants exhibit. *Gereant* has flowers which measure over 10 inches in diameter, and the colour is a glowing scarlet.

The Hon. VICARY GIBBS, Aldenham (gr. Mr. Beckett), has on several occasions made displays of new Chinese plants and *Michaelmas* Daisies. In *Buddleia variabilis gigantea* (A.M., August 30) may be seen a great improvement on the original type of this showy garden plant.

SIR TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. Bain), cultivates a large number of rare plants, and among others he has shown during the past year *Calathea crocata* (with reddish-orange flower-spikes), *Crinum purpurascens*, and *Cyrtanthus O'Brienii*.

Among the greatest favourites of the day are Roses, Carnations, and Sweet Peas. These beautiful and fragrant flowers are valuable for all purposes of decoration, and in cherishing them we follow in the steps of garden-lovers of all the ages since these plants were first cultivated. It is pleasant to see that in the art of using flowers for indoor and table decoration the decorative artist has kept pace with the improvement in the flowers. He has learned to employ full sprays with a good length of stalk and natural foliage, whilst the designs are frequently carried out with one kind of flower—Roses, Carnations, or some other species—and thus better effects are obtained than are possible from mixtures of short-stalked flowers, such as were formerly seen, even in the best florists' shops.

ROSES.

No greater innovation among garden plants has taken place for many years than the introduction of the *Wichuraiana* Roses, which now embellish even the small gardens of the suburban villas, and brighten the outlook of the passengers by railway everywhere. It seems strange that the Japanese, who are noted for discernment in gardening, should have allowed their own wild Rose *R. Lucie* (*Wichuraiana*) to suffer comparative neglect in its native country and have left it to American and European gardeners to get such beautiful results from cross breeding. A good example of these hybrids was the variety *Excelsa*, for which Messrs. Geo.

PAUL & SONS received an Award of Merit at the Temple Show. Amongst the best Roses of the year may be mentioned Juliet, for which Messrs. WM. PAUL & SON obtained a First-class Certificate at the Holland Park show; "Flame," shown by Mr. CHAS. TURNER, Slough; and Daphne, from the Rev. J. H. PEMBERTON. It may be said that Juliet was exhibited in 1909, when it gained an Award of Merit, but its distinctness was even more apparent in the last season.

At its meeting on July 8, the National Rose Society awarded Gold Medals to each of the following varieties, some of them also securing awards at the Royal Horticultural Society:—Edward Mawley (H.T., deep maroon-crimson) and Mrs. Joseph H. Welch (H.T., bright salmon

when shown on September 15 (ALEX. DICKSON & SONS). Other varieties which obtained awards during the year included the following:—Mrs. Herbert Stevens, T., with lemon-tinted, white flower (S. MCGREY & SON); Marchioness of Waterford and Mrs. Chas. F. Allan, H.T. (both from Messrs. HUGH DICKSON & SON, Waterford); Mrs. Jas. Ferguson, H.T., a very distinct Rose (from Mr. W. FERGUSON, Dunfermline); Mary Countess of Ilchester, H.T. and Duchess of Westminster, ALEX. DICKSON & SON; and Freda (from Messrs. GEORGE PAUL & SONS).

SWEET PEAS.

Of these beautiful flowers awards have been given for Marjorie Hemus (heliotrope colour)

Stent (J. AGATE, Havant), after trial of these varieties at *The Times* experimental grounds.

CARNATIONS.

These are now shown in their various classes at most of the exhibitions of the Royal Horticultural Society during the year, and at some they form the principal attraction. Mr. H. BURRETT, Guernsey, always shows finely-developed flowers, and on February 22 secured an Award of Merit for Mrs. Tatton, a fine, perpetual flowering variety, of pink tint with white, fringed edge; Mrs. R. F. Edton, a fragrant, bluish pink flower, on March 22; and Mrs. C. F. Raphael, on May 3. Carnation Edith Watts, a bright cerise flower of much fragrance, from Mr. C. F.

FIG. 17.—LILIO-CATILEYA CRANSTOUNÆ "WESTONBIRT VARIETY."

(The Award of Merit given this hybrid on January 3 has been withdrawn and a First-class Certificate awarded. See page 15.)

Rose), both from Messrs. MCGREY & SON, Portadown; Rayon d'Or (H.T., a golden-yellow flower, streaked with crimson on the outer petals, raised by M. FERNET DUCHER, and shown by Dr. WADDELL); and Lady Hillingdon (T., a fine cinnamon yellow bloom of good substance), from Messrs. LOWE & SHAWYER, one of the most admired novelties of the year. Silver-gilt Medals were also awarded for Evelyn Dauntsey H.T. (S. MCGREY & SON); Mrs. G. Shawyer, H.T., rose-pink (LOWE & SHAWYER); St. Helena, H.T., bright yellow (B. R. CANT & SONS); Mrs. Foley Hobbs H.T., a fine rose-pink flower, changing to cream colour on the outer petals, which gained the Gold Medal

and Paradise Cerise, both from Miss HEMUS, Upton-on-Severn; Prince of Orange, from Mr. STEVENSON, Woburn Park Gardens, Addlestone; Dobbie's Sunproof Crimson, Earl Spencer, and Ivanhoe, from Messrs. DOBBIE & Co., who have shown many improved varieties, Marie Cuthbertson, a soft, rosy mauve, being one of their best; Alfreda Pearson (bright pink), Messrs. PEARSON & SON; Iris (salmon colour), Mr. C. W. BREAMORE, and Mrs. F. A. Wellesley, one of the best whites.

The National Sweet Pea Society awarded First class Certificates for Cherry Ripe (GILBERT & SONS); Masterpiece, Arthur Greeve, and Mrs. Hugh Dickson (DOBBIE & Co.); and Stirling

WATERS, Balcombe, secured an Award of Merit on June 7, as did Queen May (CUTBUSH & SON), a very dark-crimson flower. On July 19 Mr. JAMES DOUGLAS, Great Bookham, made a good display, and secured an Award of Merit for Mrs. Robert Berkeley, a light pink border variety, and, again, on August 2, he secured a similar award for Finester (a yellow and crimson flake) and Mrs. J. A. Reynolds (a beautiful flower of a peculiar golden-apricot tint). Other distinguished varieties of the year were Mrs. E. Mather Smith, a white flower, from Mr. BLEVE, Hayes; Scarlet Glow and Mrs. C. W. Ward, from Mr. S. LANGE, Hampton; Rectoria, a fine salmon-pink perpetual, from Mr. C. ENGLEHART, Saffron

Walden; and Lady Alington (a charming, rich-salmon-coloured flower of the American bush class), shown by Messrs. STUART LOW & Co., of Bush Hill Park, Enfield.

At the Midland Carnation and Picotee Society's show, held at the Botanical Gardens, Birmingham, on August 4, First-class Certificates were given to the fine rose-flake Peter Pan, shown by Mrs. C. H. HERBERT; the dark-coloured Harry Parton from Mr. W. H. PARTON, and Hecla and Gloria, shown by Mr. HAYWARD MATHIAS; whilst other novelties of merit were recognised by competent authorities at the larger provincial shows.

CHRYSANTHEMUMS, DAHLIAS, AND AURICULAS.

Chrysanthemums and Dahlias, each section with its large number of devotees and under the protection of its own society, have given a goodly number of sterling novelties. The principal exhibitors of seedling Chrysanthemums have included Messrs. WELLS & Co., Merstham; Mr. H. W. THORP, Worthing; Mr. NORMAN DAVIS, Framfield; Mr. H. PERKINS, Mr. F. W. LADDS, Mr. N. MOLYNEUX; and Mr. J. DOUGLAS, whose exhibits of Auriculas are unrivalled, has secured awards for Phyllis Douglas (a white-centred Alpine), Roxburgh (violet, with primrose paste), Victor (deep-crimson, with white paste), Warley (a delicate mauve-coloured show variety), Canary Bird (a chrome-yellow Fancy), Dorothy Cutts (a pale, yellow-edged, rose-coloured flower), and May (a crimson flower with white paste).

NARCISSUS.

The favourite Daffodil has now innumerable varieties, but in some sections these are too nearly alike to be easily distinguished, except by experts. Among the novelties recognised by the Narcissus Committee during the past year were Mrs. Norman Cookson (a chaste, white variety of the Leedsii class), and Colleen (a very remarkable form), shown by Messrs. WALLACE & Co., Colchester, both securing Awards of Merit on May 3. N. Matthew Arnold (a handsome novelty), from Messrs. CARTWRIGHT & GOODWIN, secured a similar award.

(To be continued.)

SCOTLAND.

THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE operations of this society during the year ending November 30 last, show a considerable improvement. The fact that the financial position has been improved by a net gain of £28 will serve to strengthen the hands of the council in making their arrangements for the future. In the past the Royal Caledonian Horticultural Society has done so much good work that it would be a misfortune were its activities to be curtailed or weakened by lack of financial resources. The spring show especially deserves increased support from the public, and everyone is agreed that its continuance is required in the interests of Scottish horticulture. Should the proposed introduction of heating apparatus to the Waverley Market be carried out it would probably help the spring show considerably, not only from the exhibitors' point of view, but also by attracting a greater number of visitors, especially in the evenings. The members of the council and their secretary and treasurer, Mr. Donald Mackenzie, are assiduous in furthering the interests of the Society, and it is hoped that the public will support the shows even better than hitherto. It is further hoped that the amalgamation of this Society with the Scottish Horticultural Association is only a matter of time.

REQUESTS TO SCOTTISH GARDENERS.

THE late Mr. John Birkmyre, of Broadstone, Kilmacdon, has left the sum of £50 to his gardener, Mr. Joseph M. Kie, and £100 to Mrs. M. Kie. He also left an annuity of £52 to his garden labourer, Mr. Bernard M. Ardle.

GARDEN SUBURB FOR CLYDEBANK, GLASGOW.

THE garden suburb and garden city movement has not made much progress in Scotland, but several schemes have been promoted, with prospects of considerable success. One of the latest is at Clydebank, Glasgow, where a site has been selected. A considerable demand for plots for houses on this property has arisen, and a committee has been appointed to form a co-partnership to develop the site and secure the necessary capital.

GARDENING IN SHETLAND.

A CORRESPONDENCE has been going on in one of the Scottish newspapers regarding gardening in Shetland, and it is shown that the climate of the islands is greatly maligned, as is well known to those who have spent some time in "Ultima Thule." One of the latest contributions on the subject is from "Jessie M. E. Saxby," the authoress, who is a devoted gardener, and who, writing from Baltasound, says she gathered a Rose on Christmas Day. The bane of Shetland gardens is the want of shelter, for the cold winds in spring do considerable damage to flowers which come into growth early owing to the mild winters. The long days of summer are highly favourable to many plants, and enable some to flower which would not bloom so far north were the days of the normal length. The winter days are not so much shorter than in many parts of Scotland, and, on the whole, the increased interest in gardening in Shetland is being justified by the results. Mrs. Saxby has done a great deal to stimulate this by her communications to the Shetland Press. *Correspondent.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

WHAT IS A VARIETY?—Although I have already* reminded nurserymen and gardeners of the immense variability in Nature of many species of Alpine plants, according to soil, position, altitude, etc., it is so important that these frequent variations should be realised, and that the rash manufacture of new names should be discouraged, that I venture to draw the attention of your readers to two notes in the *Journal of Botany* for November, 1910, and January, 1911, by Messrs. Druce and Horwood respectively. I am constrained to do so partly because of the columns which have been devoted, during the past three months, to the question as to whether *Saxifraga hantoscana*, Boiss., should be considered a species or a variety. Incidentally, it may be remarked that Mons. Correvon's article on the Saxifrages of the Maritime Alps (*Gardeners' Chronicle*, December 10) is a useful history and summing up of the matter. May I also say that Mr. Reginald Farrer's entertaining articles are particularly interesting to those of us who know the districts he has been travelling in, however much his energy may perhaps seem to be sometimes misdirected? Had he, for example, been less obsessed with the minute peculiarities of certain Saxifrages, which naturally necessitated a difference of opinion from time to time, so careful an observer would certainly not have lamented that "nothing further did the Briga Valley yield." It is one of the richest, botanically, of sub-Alpine valleys. For the same reason, possibly, he found the beautiful Miniera Valley so "very, very dull and hot." There are points in several of these interesting articles I should have liked to allude to, and particularly to the frequent occurrence of *S. cochlearis* and *S. lingulata* in the Ligerian Alps, to the east of the Col de Tenda, a fact not mentioned in these columns, but I understand that enough has already been written on the matter. To return to

the *Journal of Botany*, Mr. Druce's article is entitled "*Saxifraga Elmaria* L. var. *denudata*, Boem.," and in a long editorial note Mr. Britten says "it is certain that the knowledge of a great herbarium tends to enlarge one's views of species, and that many plants which appear distinct when only a limited amount of material is available are found to be conspecific when a greater number of specimens comes under investigation." Mr. A. R. Horwood's reply to Mr. Druce (*Journal of Botany*, 1911, p. 16) is such an able note on the variability of plants due often to merely pathological or physiological causes, that many gardeners would be interested in it, and the subject is particularly important in the horticultural world at the present time when so much attention is given to the culture of hardy plants, often accompanied by a very natural, though unsatisfactory, trade rivalry in the introduction of so-called new species and varieties. After alluding to Mendel's discoveries, and pointing out that the ultimate test of species, variety, or form is found only by cultivation for several generations, Mr. Horwood sums up by stating that "species are the biological units once differentiated by variation, which goes on complicating original differences, so that permanent varieties occur, and at the same time plants are open to detrimental effects of environment and resulting re-action, often impermanent, as here. These must not be confused with permanent intermediate forms obtained by hybridisation and crossing, which remain constant, and are produced by definite inter-breeding. When species, variety (so-called), and an intermediate state are commingled in the same unit, it is reasonable to suggest that the two last are of no importance." Mr. C. B. Robinson alludes to "a personal friend" on the Continent in a guarded and polite manner. The fact that we are all personal friends, or correspondents, is true, but that is no reason why we should all agree as to the exact rank that *Saxifraga hantoscana* should hold. It is more important that not even the youngest gardener should ever again doubt that *S. cochlearis* and *S. lingulata* are absolutely distinct. *H. Stuart Thompson.*

DIJON TEA ROSE.—The Dijon Tea mentioned in vol. xlviii, p. 463, by your correspondent R. P. S., as being the last one raised by Lacharme, was "Henriette de Beauvau," a most beautiful variety, but, unfortunately, proving rather tender. *G. L. P., Cheshunt.*

BANANA CULTURE IN ENGLAND (see vol. xlviii, p. 464).—It is a matter for wonder that the Banana is not more often grown in this country, seeing that the home-grown are so much better than imported fruits. In these gardens there are two plants of *Musa Cavendishii* growing in a border in the plant stove. From the numerous suckers which spring from the base, one is chosen from each plant, and allowed to develop, while the parent plant is carrying its fruit. By this method time is saved, and a bunch is secured in 15 or 16 months. If care is taken not to allow a sucker to grow away too early, the fruits will attain their full size. When the fruit is cut, the old plant is removed, and the soil about the roots taken away and replaced with fresh, rich compost. The young plant—by that time 4 feet or 5 feet high—soon becomes established and grows into a fruiting specimen with a girth of stem at base of 3 feet. The plants require abundant waterings and manure, and frequent slight top-dressings of loam, with a good fertiliser added. Two bunches which ripened in September and December, 1910, carried 162 and 251 "fingers" respectively. These fruits were plump, clear-skinned, and of delicious flavour. The largest weighed 7 ounces, and they averaged 2½ to 3 fruits to the pound. *J. Lisney, Berwick House Gardens, Shrewsbury.*

—Imported Bananas are not acceptable eating to those who know them in the countries in which they are grown. For one thing, they

* *Gard. Chron.*, July 23, 1910.

are mostly the commoner varieties, and the fruits are gathered before they are fully ripe, and, consequently, they are poor in flavour, and altogether unfit for dessert at the best tables. Anyone who has grown *Musa Cavendishii*, a native of Southern China, or *M. sapientum*, an Indian species, and taken the fruit when quite ripe, will agree with me in this matter. I have grown the first-named *Musa* as an article for the table in a southern county, sending it in for dessert regularly. When the various plants ceased to fruit, the mother plant was rooted out and its sucker, which pushed up its side was cultivated in its place. The glasshouse was a high one, about 15 feet at that part where the *Musas* grew, and it was a half-span, constructed originally for ainery, but made use of later for plant-growing, and well furnished with water pipes. The Bananas occupied the space at the back, standing about 5 feet from the back wall, thus allowing ample space for the plants without in any way hindering the passage of anyone who might wish to pass between the plants and the wall. The central space contained no staging, therefore there were no impediments to overcome in finding space for the *Musas*; and I was enabled to dig out pits for them 3 feet square, and about the same in depth. In these holes, which were undrained, the soil being of a porous nature and on a declivity which ensured perfect drainage without artificial means. The pits were filled with rich, rather heavy loam, with which some stable manure and considerable quantities of finely broken sandstone and charcoal were incorporated. The *Musas* planted were young and about 5 feet high; they came out of pots about 2 feet in diameter, and may have been 18 months old. They were well supplied with water at planting time—early in the spring. When the soil indicated dryness, a 3 gallon bucket of water was applied—perhaps once a month till winter approached, when much less is required. When the oldest plant showed the fruiting club near the base of the oldest leaves 15 months later, it came to me as a surprise, as I had thought more time would have elapsed ere the fruit might appear. But under glass cultivation in this country the fruiting is erratic, hence the wisdom of having at all times several plants of various ages. The bunch was about 3 feet long, and it consisted of about 150 fruits, of which I sacrificed 50 that grew on the lower end and were removed because of their small size. The remaining fruits had an average length of 7 inches, and were gathered only when of a yellow colour and emitting a delicate aroma—the signs of perfect maturity. Eight to ten weeks elapsed from the time the bunch pushed up through the upper part of the stem till the first fruits ripened, and they then came into use in a long succession, extending to six weeks, or longer, according to the sun's heat at the time. *F. M.*

ABUTILON THOMPSONII AND A. THOMPSONII SPURIUM.—I join issue with Mr. Brown in all he says (see *Gardeners' Chronicle*, December 31, p. 439). Indeed, it is not at all likely that we should differ in speaking of the same thing from the same point of view. Mr. Brown thinks I may have overlooked the fact that the wild plant in its native country varies in pubescence, and believes it is not absolutely certain that the plant may not have done so here under open-air cultivation for a number of years. His remark, I think, leads up to a point of interest and importance, from an evolution as well as from a garden point of view. It is not, of course, absolutely certain, as Mr. Brown says, that the plant has not varied in the character of pubescence in course of cultivation (there is also the different colour of the flower, and, I think, some difference in form), but for reasons that will, I dare say, appeal to my old friend, whose acumen I know so well, I believe it to be extremely unlikely. It is undoubtedly true that wild variation does exist, but it is equally true and certain, I think, that the variation is exclusively from seed, and that of all the variants we have only, perhaps, one in cultivation, propagated, of course, to an unlimited extent by cuttings, but remaining, nevertheless, one individual. The wild individual plant is not likely to vary under native conditions because environment would remain the same; the variations then that have been collected must be from seed, as, indeed, would be most likely, and so we have no evidence whatever of any individual variation. In the garden,

I think it may be said, we have never seen a similar variation in any individual plant of any kind—a new creature has been born, and never in nature, I believe, has it happened in this way. The conditions under which *Abutilon Thompsonii* has been cultivated have never been known to produce a change such as that of *A. Thompsonii* into *Thompsonii spurium*. Variation of the individual is normally, I believe, nothing more than casual adaptation, while variation from seed is quite a different thing. With regard to *A. striatum*, I would point out that we have in it a very clearly defined, unvarying species, so far as gardens are concerned. It is one of a number of variants of an aggregate species, no doubt. It shows not the slightest tendency to vary in any normal way, with even a greater number of years at its disposal, and the other individual *Abutilons* in cultivation are no more likely to vary. Turning to abstract argument, I think it may be pointed out that plants vary in two ways, comparable with physical and chemical change respectively. The variation of the individual plant is like the physical change: it is reversible; there is no change of composition, and nothing permanent is effected. It could not evolve, I think, a new and permanent creature, such as I judge this *Abutilon Thompsonii striatum* to be. In contrast with variation of the individual plant, there is variation from seed, which may be compared to chemical change: it is permanent, the young varying plant is new in composition, and this means everything in evolution. The power of this kind of variation, it seems to me, was necessary in the production of *Abutilon Thompsonii spurium*, and, if I am correct, it is therefore not one and the same individual as *A. Thompsonii* merely changed in aspect. One point more I would allude to, and that is the question "how comes it that the false *A. Thompsonii* is now so widely cultivated, to the exclusion of the true, and how has one replaced the other?" The answer, I think, must be that it is a finer plant for the purpose for which such a plant is used in ornamental gardening. The finer plant somehow appeared, and, being found good, took the place of *Abutilon Thompsonii*, and, being somewhat similar, took the name at the same time. It was simply a better *Thompsonii*. Bedding-out gardeners are not as a rule at all critical as to names, and do not care what a plant is, or where it comes from, provided it serves the required purpose. *R. Irwin Lynch.*

ABUTILON THOMPSONII FLORE PLENA.—The following items concerning the origin and early history of this *Abutilon* may be of interest to Mr. Lynch and others. In the spring of 1884 among the new plants offered by M^{rs}. V. Lemoine et fils, of Nancy, was this *Abutilon*. I at once obtained a plant, which, in foliage, was indistinguishable from the ordinary *A. Thompsonii*. The flowers, however, proved to be quite double, but, to my mind, they were much less pretty than the single forms, for which reason it was after a few years discarded, though I see it is still quoted in one nurseryman's catalogue now before me. When interest was, in the *Gardeners' Chronicle*, aroused over *A. Thompsonii* and its allied forms, I wrote to Messrs. Lemoine, asking if they could give me any information regarding the double variety sent out by them in 1884. With their usual courtesy, they replied that this variety was obtained from Messrs. Peter Henderson, Cortland Street, New York, who distributed it the year previously. I then inquired of Messrs. Peter Henderson & Co., who, in a long and courteous communication, informed me that it originated as a sport from the ordinary single variety in 1832. It was first noticed by Mr. Alexander Kennedy, gardener to John Taylor Johnson, Plainfield, N.J., U.S.A. One large plant bore on a single shoot flowers that proved to be double, and cuttings being obtained therefrom, they maintained this character. The stock then passed into the hands of Messrs. Peter Henderson & Co., who distributed it in 1863. In the various notes on the variegated *Abutilons*, I have seen no mention of an old kind which used to be employed for bedding purposes under the name of *A. niveum marmoratum*. It belonged to the *Thompsonii* class, and though I have not seen it for some time, it is still catalogued by Messrs. Cannell & Sons, of Swanley. *Abutilons* with variegated leaves are decidedly numerous, for besides those that have been mentioned are *A. Solovianum variegatum*, which requires somewhat more heat than the rest. The leaves of this are

large, almost horizontally disposed, and marked with green and pale yellow in varying proportions. In *A. Darwinii tessellatum* the leaves are marked in a tessellate manner with creamy-yellow. The distinct and curious-flowered *Abutilon insigne* is also represented by a form in which the large rugose leaves are mottled with yellow. Under the head of *Abutilon Schwartzii*, Mr. Lynch inquires the origin of a white variegated form, which I take it is the same as that usually grown in nurseries as *A. Savitzii*. This information I regret being unable to give, but at the same time I should like to point out that there is an older variety with white variegation, namely, *Souvenir de Bonn*, which was given an Award of Merit by the Royal Horticultural Society on April 25, 1893. This is a more vigorous grower than *Savitzii*, and the white edging does not extend so far over the leaf as in that variety. Added to this, *Souvenir de Bonn* is less pubescent than the other, and the leaves are altogether harsher to the touch. The flowers are, I believe, as in *A. striatum*. *W. Truelove.*

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The voting paper recently sent to supporters of this gardening charity includes the names of no fewer than 73 candidates, of whom about 20 may be elected. Many thousands of persons interested in gardening do not receive these lists, because they are not subscribers. Each year brings new candidates, there being no fewer than 32 new applicants this year, yet there are 25 persons on the present list who have applied for the benefit unsuccessfully for three years and upwards. If, out of the many thousands who are non-subscribers, but one or two hundreds were to become supporters, the elections might be extended from 20 to 30. If any person has doubt as to the needs of the institution, let him send at once to the secretary, Mr. Ingram, 92, Victoria Street, Westminster, D.

NOTES FROM NEW ZEALAND.

I HAVE just received a letter from a gardening friend who lives at Dunedin, New Zealand. My correspondent writes: "I am glad to know that the *Ranunculus Lyallii* plants arrived in good condition. Even here they are difficult subjects, as much wet in winter is bad for them. I note what you say about *Celmisia* doing best in the shade at Kew, and probably it is a mistake to expose them fully to the sunshine, for they are mostly mountain plants and, even where they will get all the sun that is going, it will often be obscured by mountain mists. *Celmisia verbascofolia*, which grows at a low altitude, is found among the rocks and scrub in a gorge in the Horse range, so that it must get a good deal of shade some time in the day. On the contrary, *C. Lindsayi* drapes the rocks on the open coast to the south of this, where the plants must be in the full sun for the greater part of the day. I daresay partial shade would suit most of them, but, of course, if at Kew full shade is found to be best it will be wise to follow their lead. *Convolvulus luguberrimus* grows wild in places quite near here. It is now classed as a *Calystegia*, though it was originally described as a *Convolvulus*. If it does well with you, I am sure you will like it, as it has a neat, compact habit of growth for such a rampant climber, and its white flowers are numerous, though only about an inch and a half across. It is to my mind a most desirable plant. Strange to say I have never established it in my garden, though I have made one or two attempts. Probably my want of success was due to my not giving them any care, but only a few days ago I planted out a couple of seedlings which I had raised, and, as I have taken more pains to give them a good rooting medium to start in, I hope in time to have them draping an old specimen *Pittosporum*. When once firmly established they will hold their own in the most disadvantageous conditions, as I have seen one growing through a hedge of *Cupressus macrocarpa*. I have not grown *Ostrowskia magnifica* satisfactorily, though I have imported it twice. The first plant lived for a year or two and then disappeared, and those I now have, I am afraid, are likely to fail. I dug a large, deep hole, which I filled with pieces of limestone mixed with soil, as I had read that the species liked rough, stony soil and limestone for preference.

but the first year the plants only threw up feeble growth an inch or two above the ground, and this year they have behaved similarly. It may be that the drought has been too much for them, for we have had three very dry years. I do what I can with the garden hose, but it forms a poor substitute for the natural moisture. My collection of *Eremuri* has suffered very much this year from the drought, some have turned yellow and withered away, whilst one that threw up two flower-stems is not going to develop its blossoms. One, however, *E. Olge*, is going to flower. *E. caucasicus* flowered last year, but is a failure this year.

Pueraria Thunbergiana I tried once, but failed to establish it. It arrived alive, but had no vigour and gradually dwindled away. Recently, while on a visit to the North Island, I saw *Akebia quinata* covered with flower, yet I have had it for years, and it has grown very vigorously and is now smothering other things on the same trellis, but it has never flowered with me. *Lardizabala biternata*, *Rosa laevigata* and *Stauntonia hexaphylla* have all behaved in the same way. Possibly, if I had them against a wall instead of on a trellis they might flower, but often in the summer there are chilly winds which blow up the harbour and, as my garden faces the north-east, it is exposed to it, and I attribute the non-flowering of several plants to this cause. For example, *Spiraea prunifolia*, which at Queenstown, on the shores of Lake Wakatipu, where the winters are tolerably severe (all the big Blue Gum trees were killed there one winter) flowers splendidly, the bushes being hidden with blossom, whilst here it flowers but sparingly, and it is the same with some other plants. It is very difficult to ascertain the cause of failure. The common Crown Imperial will not flower with me, though I have tried it in various situations, and the Corporation gardener (a Kew-trained man) tells me that his experience is similar. The city gardens are at the other end of the town and have a different aspect, so that the conditions are totally dissimilar, yet in other gardens it thrives, and at one place in the country it grows and flowers luxuriantly. My bulbs, year after year, throw up a stem 2 feet or 3 feet high, apparently healthy, but these shortly after wither without flowering.

I have succeeded in growing the ordinary greenhouse *Cineraria* in the open air, and my bed, which contains both the old form and the newer *stellata* variety, is a mass of colour. I got the idea from a cottage garden in the neighbourhood, where the owner had a small bed of *Cinerarias* between his house and the adjoining one, the latter having a brick wall, the reflected heat from which might, I thought, have something to do with the success achieved, but possibly the shady situation was the main thing. I pricked out my seedlings into a box, and in the autumn planted them in a bed shaded by trees, where they stood all the winter, and are now bearing blooms that would not disgrace greenhouse plants.

I prefer flowering shrubs to anything else. My last importation was not a great success, as I think I lost fully 75 per cent. of the plants, but I am glad to say *Lomatia ferruginea* is doing well, and I am greatly pleased with its foliage."

With regard to the *Celmisias* mentioned by my correspondent, I may say that when I was at Kew during the past summer, I was shown by the superintendent of the temperate house the collection of these plants growing just behind the house, and was told that they got no sun until five o'clock in the day. I had always grown my *Celmisias* in the sunniest spot available, and had lost several of them and came to the conclusion that a certain amount of shade was beneficial for them.

From all accounts the climate of Dunedin is very much the same as that of the south-west of England, as my correspondent says that in hard winters he always loses his *Pelargoniums* grown in the open, and in the foregoing letter he speaks of Blue Gums (*Eucalyptus*) being killed, whereas here, at Kingswear, there are many Blue Gums which have been unharmed for years. It is therefore probable that we could grow any of the plants of the south of New Zealand without protection, and I think that little difficulty would be experienced in cultivating *Cinerarias* in the open, as described by the writer, if anyone cared to embark on the attempt. *Wyndham Fitzherbert*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 3.—*Present*: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the Chair); Dr. A. B. Rendle, F.R.S., Messrs. A. W. Hill, M.A., J. Odell, W. Hales, J. T. Bennett-Poë, M.A., E. M. Holmes, F.L.S., W. Fawcett, B.Sc., and F. J. Chittenden (hon. sec.).

Sporting in Begonias.—Mr. J. HUDSON, V.M.H., sent a specimen showing sporting in winter-flowering *Begonias*. Last year a sport had appeared on *Begonia* "Agatha," with flowers larger and of a brighter colour than those of the type. Plants are propagated from the sport and came true, but on one plant one half again sported and produced flowers still larger than in the first sport and with foliage twice as large. The Committee expressed the hope that specimens of each of these sports should be kept and dried, so that comparisons could easily be made in the future and the whole history of the sports followed.

FIG. 18.—SEED-PODS OF MANDEVILLA SUAVEOLENS.

Fruiting of Mandevilla suaveolens (see fig. 18).—Mr. CHITTENDEN showed, on behalf of Mr. SAUNDERSON, of Joanyville, Jersey, a pair of fruits of *Mandevilla suaveolens*, which had ripened in the garden there. This plant can be grown outdoors only in warmer parts of England, and is not often known to fruit. The fruits, as in so many of the *Asclepiadaceae* are pods about 12 inches in length and slender, and are produced in pairs.

Pine-apples with rotten core.—Some Pine-apples of excellent flavour, but with a brown rot in the core, were received from Natal. Mr. FAWCETT said that the condition was very well known in the West Indies, and was particularly prevalent in the variety shown, which Mr. FAWCETT recognised as the deliciously-flavoured "Ripley." Whatever the cause, he believed it originated before the Pines were cut, and, therefore, whilst they were growing. The rot has been attributed to different causes by different investigators. It has been examined in the States and said to be connected with the growth of a species of *Fusarium*, which, presumably, gains an entrance into the root from the soil, but the disease does not appear to have been reproduced by inoculation by this fungus (see

Jamaica Botanical Bulletin, ser. ii., vol. viii., (1901), p. 83, vol. xi. (1902), p. 165. Mr. MASSEE, in his *Diseases of Cultivated Plants*, attributes the disease to physiological causes, pointing out that it is prevalent when the plants are ripening during the rainy season, and associating it with excess of water in the atmosphere. A similar trouble occurs in pine-pits in this country, especially when the plants are subjected to a check through a sudden lowering of the temperature.

MANCHESTER AND NORTH OF ENGLAND ORCHID

JANUARY 5.—*Committee present*: Messrs. E. Ashworth, R. Ashworth, Thorp, Ward, Cowan, Holmes, Cypher, Keeling, Smith, Arthur, Parker and P. Weathers (hon. sec.).

Messrs. CYPHER & SONS, Cheltenham, were awarded a Silver-gilt Medal for a group composed mainly of *Cypripediums*, including choice forms of *C. × Euryades*, *C. × Leeanum* in variety, and *C. × Beeckmannii*. Some well-grown plants of *Sophronitis grandiflora* and *Masdevallia Schröderiana* were also noticed.

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), staged a showy group of plants, including many well-grown specimens of *Odontoglossum* with fine flower-spikes and several good *Cypripediums*. (Silver-gilt Medal.)

S. GRATRICK, Esq., Whalley Range (gr. Mr. Brown), exhibited *Cypripedium × Sunbeam*, a well-shaped yellow and white flower, and *C. × Alport Regina*, both of which received Awards of Merit.

W. R. LEE, Esq., Heywood (gr. Mr. Woodhouse), again staged an interesting exhibit, which included *Odontoglossum × Ceres* var. *magnificum* (*O. Rossii × O. × Rolfeae*), one of the best forms of this pretty hybrid.

E. V. LOW, Esq., Vale Bridge, Haywards Heath, showed a few plants, including a fine example of *Cypripedium × Gaston Bultel*.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Gilden), made a fine display of Orchids, for which a Silver-gilt Medal was awarded. Good forms of *Odontoglossums*, both species and hybrids, formed the major portion of the group. *O. × Red Monarch*, closely approaching a form of *O. crispum* and *O. × "Blue Peter,"* a beautifully-coloured hybrid, received First-class Certificates, whilst *O. × Moonlight*, apparently a hybrid of *O. crispum* var. *Grairianum*, received an Award of Merit.

J. H. CRAVEN, Esq., Keighley (gr. Mr. Corney), exhibited a few Orchids, of which *Cypripedium villosum* var. *Mrs. Cary Batten* was the best example.

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), showed a group of *Cypripediums*, for which a Silver Medal was awarded.

Messrs. KEELING & SONS, Westgate Hill, near Bradford, exhibited a small collection of miscellaneous Orchids.

Messrs. SANDER & SONS, St. Albans, staged many interesting plants, including well-grown specimens of *Odontoglossum* hybrids, with fine arching and branched flower-spikes.

Mr. WEBSTER, Shackleton, showed, amongst other plants, a distinct form of *Cypripedium × Acteus*.

PEEBLESHIRE HORTICULTURAL.

A GENERAL meeting of the above society was held recently in the Drill Hall, Peebles. Mr. Oldham presided over a good attendance of the members. The hon. treasurer, Mr. Forrest, submitted a statement of the society's financial accounts, which showed a credit balance of more than £18. The date of the next show was fixed for August 24. Officers were appointed and the schedule of the flower show revised.

FOREST HILL CHRYSANTHEMUM.

JANUARY 5.—The annual meeting of this society was held on the above date. A very satisfactory report was read, and the balance-sheet showed a credit to the good of over £11. The members of the committee were all re-elected, and Mr. E. G. Marshall appointed to the new office of Press correspondent. A lecture will be given before the members on January 18, at St. Saviour's Hall, Forest Hill, by Mr. R. B. Leech, on "Chrysanthemums."

MARKETS.

COVENT GARDEN, January 11.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ems.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers such as Anemone fulgens, Anemones (French), Arums, Azaleas, Camellias, Carnations, Chrysanthemums, Gardenias, Helleborus, Hyacinth, Lilac, Lilium, Marguerites, etc., with their respective prices in s.d. and s.d. s.d.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage plants such as Adiantum, Asparagus plumosus, Berberis, Ferns, etc., with their respective prices in s.d. and s.d. s.d.

Plants In Pots, &c.: Average Wholesale Prices.

Table listing various potted plants such as Aralia Sieboldii, Erica byemalis, Eranthis, Ficus, etc., with their respective prices in s.d. and s.d. s.d.

Fruit: Average Wholesale Prices.

Table listing various fruits such as Apples (American), Grapes (English), Lemons, Melons, Nuts, etc., with their respective prices in s.d. and s.d. s.d.

Potatoes

Table listing various potato varieties such as Kents, British Queen, Bedford, etc., with their respective prices in s.d. and s.d. s.d.

REMARKS.—Trade remains very steady, and prices are about the same as those of last week. E. H. R., Covent Garden and St. Pancras, January 12, 1911.

COVENT GARDEN FLOWER MARKET.

Many growers endeavour to be first in the market with forced flowers, and, in consequence, after the first few markets, larger supplies are seen than a little later. Tulips are already abundant, but fairly good prices are being made; they include good white, yellow, pink, and red sorts. Roman Hyacinth is well supplied, and is offered below the usual prices. Narcissi include Golden Spur, Felamonus, and Henry Irving (yellow varieties); also Soleil d'Or, Primo, and Paper-white. The supplies of this flower to-day (Wednesday), were equal to all demands. All who are interested either in selling or buying flowers should visit the market occasionally to obtain a knowledge of the general conditions, including the difficulties of securing just what is wanted, and also the losses that occur through waste blooms. Good white Azalea was in demand this morning, and the blooms were making prices beyond the ordinary quotations. Chrysanthemums are well supplied, best quality flowers have been making fairly good prices, but bunches of smaller flowers have not been in much demand. Roses vary, both in prices and quality. Richmond and Mme. Abel Chatenay are the most valuable varieties in the market. Kaiserin Augusta Victoria also has a good demand. Most growers have finished with Poinsettias for the season, and prices for good heads of bracts have advanced; from now onwards the supplies of this showy subject will be very uncertain, though some may be procurable as late as February. Liliums are well supplied; there is a considerable difference in the quality of the flowers, and prices vary accordingly. French flowers arriving in large quantities; their prices fluctuate, and the same is true of all cut flowers.

POT PLANTS.

Very few pot plants have been wanted during the past week, and there is but little change in the sorts offered. Chrysanthemums of good quality are procurable, but many growers have cleared their stocks. Supplies of Erica byemalis promise to hold out for some time yet; E. gracilis is scarce, and E. gracilis vernalis (which succeeds E. g. autumnalis) is not so extensively grown as formerly. E. melanthera is still procurable. Liliums in pots vary in height; some well flowered dwarf plants of L. Harrison are of good quality. Cyclamens are not yet quite up to the high standard of quality usually seen in January, but they are fairly good. Solanums are procurable, but the berries are beginning to drop, and consequently they cannot be sent far by rail. Azaleas (Indian) are well flowered from the usual growers. Narcissus obvallaris is seen in good condition. All kinds of foliage plants are well supplied, but the demand is very limited. A. H., Covent Garden, January 11, 1911.

LAW NOTE.

PROSECUTION UNDER THE PHARMACY ACT.

HIS HONOUR JUDGE RUEGG, K.C., sitting at the Stafford County Court, on the 6th inst., heard a case in which James Daly, seedsman and florist, of Newport Road, Stafford, was sued by the Council of the Pharmaceutical Society of Great Britain (through Mr. Richard Brimbridge, the Registrar) for £5, the amount of a penalty, alleged to have been incurred by the defendant on October 24 last, by reason of his having sold, or kept open shop for the retailing, dispensing, or compounding of, poison, to wit, a poisonous vegetable alkaloid called nicotine, contained in, and forming part of, the ingredients of a compound known as "X.L. All Vapourising Fumigator," contrary to the provisions of the Pharmacy Act, 1868 (31 and 32 Vic., cap. 121), as amended by the Poison Pharmacy Act, 1903 (8 Ed. VII., cap. 55).

Mr. Marshall, opening the case for the plaintiffs, said that the defendant was a seedsman and florist, and was licensed under the Act of 1903 to sell poisonous substances to be used exclusively for agricultural or horticultural purposes, in the destruction of insects, provided he conformed with the regulations of the Pharmacy Act, 1868. By the latter Act he was required to affix to the vessel or receptacle containing any poisonous substance he sold a label giving the name and address of the seller. The facts were that, on October 24, a representative of the Society went into the shop of the defendant in Stafford and purchased a bottle of "X.L. All Vapourising Fumigator." In his report, he described it as the usual No. 5 size bottle properly described, but it bore no label with the vendor's name and address. This was the whole of the defendant's offending.

Mr. James Richardson, inspector for the Pharmaceutical Society under the Act of 1903, stated

Vegetables: Average Wholesale Prices.

Table listing various vegetables such as Artichokes, Beans, Carrots, Celery, etc., with their respective prices in s.d. and s.d. s.d.

REMARKS.—Supplies of Apples are shorter, and prices show an increase. Peas are scarce; the variety, Passe Crassane, from France, is the best sort obtainable for dessert purposes. The Grape trade shows an improvement in prices, especially for Black Alicante and Canon Hall Muscat. Forced Strawberries have been received from the Worthing district; both the demand and supply are limited. Consignments of fruits from Cape Colony, which arrived this week, were disappointing, owing to the bad condition of the fruits. Tomatos from the Canary Islands are arriving in capital condition, and are meeting with a good demand at moderate prices. Vegetables, especially those forced, are selling well. Trade generally shows a decided improvement. E. H. R., Covent Garden, January 11, 1911.

that on October 24 last he purchased at the defendant's shop a small-sized bottle of "XL-All Vapourising Fumigator." He was served by the defendant, who brought it from a room at the back of the shop. He did not put any questions to witness, but asked him to sign the book, which, he said, was the poisons book, and witness did so. Witness opened the package some 60 or 70 yards from the shop, and found that the bottle did not bear the label giving the name and address of the vendor. He made a note on the brown paper of the name of the town and other particulars, and noted the time, etc., on another piece of paper. When he reached home that night he again examined the bottle, and affixed to it a note of the time and date, and his initials.

In cross-examination by Mr. Watson, witness said he lived at Hunton Road, Gravelly Hill, Birmingham. He received no commission in respect of the penalty imposed under the Act. He presumed the object of affixing the label was to enable the seller to be traced, while the object of the poisons book would be to trace the purchaser. It was important, under the Act, that the purchaser should give his name and address. Witness gave his name, but he admitted that he gave a fictitious address—for a purpose. The address he gave was "J. Richardson, Milford," and he signed the entry in the book.

Mr. Watson said it would have been easy for the inspector, after he had completed the purchase, paid the money, and signed the book, to say, "I am an inspector under the Pharmacy Act, and I must look at my purchase." That would have been an easy and an honest thing for him to have done. Instead, he left the shop, and opened the parcel 60 or 70 yards away. When he found that the label was missing, why did he not go back and tell the defendant so? He sent it to the Society at once; but not one word of complaint did the defendant receive from the Society until a letter was received from the Society's solicitors on November 4, telling the defendant that he had incurred a penalty of £5, payable to the Society, and calling upon him to pay the said penalty and costs. Defendant answered on November 6, saying that he could not understand why they should accuse him of that offence. He wrote: "I distinctly remember selling to Mr. J. Richardson, on October 24, a No. 4 bottle of 'XL-All Fumigator' compound, and seeing one of the enclosed labels attached before he signed for it."

His Honour, in giving his decision, said the question he had to decide was, "Did the defendant comply with the conditions required by the Act?" He had come to the conclusion that he did not. "I believe," said his Honour, "that the bottle was sold without the label being attached, but how that came about I am not sure. I do not think it has been proved that it was the defendant's habit to sell bottles of poison without any label affixed. On the contrary, he had labels specially printed for the purpose. Whether the omission in this case was accidental, or whether defendant was not as careful as he should have been, I cannot say; but there is no excuse under the Act. It does not matter in the least about the inspector giving a false address. It is what is done by all inspectors. It is done continually by inspectors under the Food and Drugs Act. I must say I am sorry for the defendant. There is no moral reflection on him whatever. It might not have been his fault in the least. As a man of business, he does not seem to have been quite as careful as he ought to be in dealing with the dangerous poisons; but I dare say it is very true that a great many people do not carry out the Act of Parliament to the letter. In this particular case, if it had been open to me to do so, I should have imposed only a small penalty, for the offence was a minor one; but the Act fixes the penalty at £5, and I must give judgment for the plaintiffs for £5."

GARDENING APPOINTMENTS.

- Mr. F. WITHERS, for the past year Gardener to J. UPTON, Esq., Tew House, Hampton, Oxon, as Gardener to COLONEL WARDE, M.P., Barham Court, Maidstone, Kent.
- Mr. J. WRIGHT, for 2 years Foreman at Bear Wood Gardens, Wokingham, as Gardener to G. H. WILLIAMS, Esq., St. Dunstons Castle, Llantwit-Major, Glamorgan-shire.
- Mr. H. E. HUGHES, for the past 124 years Gardener to Sir FRANCIS E. HAY, Bart., King's Meadows, Pebbles, N. B., as Gardener to J. H. SCOTT, Esq., Lower Woodside, Hatfield, Herts.

ANSWERS TO CORRESPONDENTS.

AMERICAN HORTICULTURAL PAPERS: W. C. *The Florists' Review*, published every Thursday by the Florists' Publishing Co., 530-560, Caxton Building, 334, Dearborn Street, Chicago; *Horticulture*, published on Saturdays, at 11, Hamilton Place, Boston, Mass.; *The American Florist*, published on Saturdays by American Florist Co., 324 Dearborn Street, Chicago; and *The Florists' Exchange*, published by the A. T. D. La Mare Printing and Publishing Co., Ltd., 2, 4, 6, and 8, Daane Street, New York. These are amongst the more important papers published in the gardening and nursery trade interest in the United States.

GYPHOPHILA PANICULATA FL. PL.: *M. Rees*. There are more methods than one of propagating this plant quickly, and at various seasons. The shoots may be layered almost the same as Carnations. First remove all the soil close down to the roots, without injuring these, then topdress with good calcareous loam and finely-powdered old mortar rubble, the Gypsophila being a lime-loving plant. Partially sever the shoot, as in a Carnation layer, and peg it down upon the fresh soil and cover it lightly with mould. This operation should be done as soon as growth commences. If a plant, or more than one, can be set aside, and the flower-shoots removed for one season, better results will be obtained. Division of the old stools may take place early in the season. Choose favourable weather, and proceed as with the layering as regards soil, but cut through the old growth behind the latest made roots and press all down firmly. When growth has fairly commenced, the divisions can be taken away and replanted. Cuttings should be taken with a heel attached during the spring, and inserted in similar soil to that already described, under a bell glass and away from the sun's rays. Cultivators should bear in mind that slugs are particularly fond of the young shoots in the spring, and they will destroy them unless preventive measures are adopted, such as occasional dustings with freshly-slaked chalk lime, which will, at the same time, be a deterrent to both earth-worms and wire-worms.

MUSHROOM BED: *Stort*. Can you send specimens taken from the surface of the bed?

NAMES OF PLANTS: W. H. S. 1. *Cologyne fuscocens*; 2 and 3, varieties of *Lelia albida*.—*Thomas Burg*. *Eriobotrya japonica* (Loquat).—*B. P.* 1. *Pinus Laricio*; 2. *Juniperus virginiana humilis*; 3 and 5, *Cupressus Lawsoniana*; 4, *Cupressus Lawsoniana* var. *Alumii*; 6, *Aspidium falcatum*.

NECTARINES: T. C. H. Nectarines are usually budded on the Plum stock, preferably such varieties as the *Musiel* and *Myrobalan*. These are produced by planting seeds (stones) as soon as they are ripe, or early in the year, in drills. The following season the seedlings may be transplanted in rows about 2 feet, 6 inches apart, and 1 foot between each plant. These plants may be used for working dwarf trees when two years old, but for standard trees they will require perhaps three or four years in which to make sufficient growth to form the stem necessary for a standard. The budding is usually done during the months of July and August, the method termed shield budding being generally adopted. If you visit a good fruit nursery at that period, you may see a practical demonstration of the budding process. Much time may be saved by purchasing a number of stocks and planting them at once. In future, you might plant seeds annually for raising what stocks are required. If you do not wish to bud the stocks yourself, you may buy maiden trees, that is, trees which have made one season's growth after the budding. These young trees should be cut back early in the spring to five or six buds. The resultant growths will form the basis of the training which you intend to adopt. The chief insect enemies of Nectarines are the green and black fly. These can be destroyed by syringing with strong, soft-soapy water.

PINE-APPLE CULTURE: W. J. M. It is possible for you to grow a Pine-apple from the growth obtained from the top of the fruit, provided you have a suitable atmosphere in which to

grow it. The Pine-apple requires a house where it can be grown near to the roof-glass, where a hot-bed can be made in which to plunge the pot. There must be sufficient water pipes to maintain a minimum temperature of 65° or 70° during the growing season; a Cucumber house would answer your purpose. The plant should be first potted into a 5-inch pot, in good fibrous loam. Plunge the pot into a hot-bed made of Oak or Beech leaves, and having a temperature of about 80°. No water should be given till the roots reach the side of the pot, when the ball should be thoroughly moistened. The plant should be shaded from bright sunshine until it is rooted, and the atmosphere must be kept moist by frequently damping the floor and walls of the house, also lightly spraying the plant, twice daily during sunny weather. When the plant has filled the pot with roots, give it a shift into a 7-inch or 8-inch pot, treating the plant as before, until it requires the final shift into a 9-inch or 10-inch pot. The loam for these two last pottings should have some crushed bones and a little charcoal mixed with it. During late autumn and winter the plant should be rested by lowering the temperature of the house to 60°, and keeping the atmosphere less moist. Early in the following spring the hot-bed should be renewed, and the plant should be more liberally treated, in regard to heat, moisture and manurial stimulants; the stimulants may be given in the form of liquid manure, soot-water, and guano.

RICHARDIA AFRICANA WITH TWO SPATHES: *D. P.* The abnormality is not uncommon; we frequently receive specimens during the season. The spadix includes the flowers proper, the spathe being a bract or modified leaf.

ROSE SHOOTS: *I. J.* The Rose shoots are attacked by the parasitic Rose canker, caused by the fungus *Comothrium Fuckelii*. You will find a good account of this disease in the *Journal of the Royal Horticultural Society*, vol. xxxiv., Part II., p. 222. Cut off and burn all shoots showing "cankers" or white areas dotted with black spots. If reddish or discoloured markings—indicating the first stages of the disease—appear on some of the shoots during next season, try painting them over with a coat of creosoted wood tar.

VINES: T. C. H., *Kent*. Vines are generally grown from "eyes" taken from well-ripened shoots, of moderate strength, from the previous season's growth. These are cut with about half an inch of wood each side of the bud, and inserted in fine soil in 3-inch pots. Put one "eye" into each pot, and press it down until the bud is level with the surface of the soil, afterwards applying a watering with a fine rose; then plunge the pots into a moderately warm hot-bed in a house where the atmospheric temperature is 70°. When the buds commence to grow, much care must be exercised in watering and syringing, or the shoots may damp off. Repot the young plants into 6-inch pots before they become pot-bound, and again plunge them in a hot-bed, and apply water carefully till the roots have quite filled the pots, when they must be shifted in the final pots, using a compost of loam, old mortar rubble, and crushed bones. Vines require plenty of heat and moisture all through the growing season, and when they are well rooted in the final pots some stimulants may be given in the form of liquid manure, soot-water, and occasional sprinklings of some approved fertiliser. In the autumn, when growth is completed, attention must be given to the maturing or ripening, as it is termed, of the canes. At this period less atmospheric moisture must be given, and plenty of air admitted, both at the top and bottom of the house. If red spider appears on the leaves, syringe them with a strong solution of soft soap and sulphur.

APPLES IN DORSET.

HINTS TO SMALL GROWERS.

THE quiet, cattle-loving county of Dorset, though not comparing with its neighbours, Somerset and Devon, as a fruit region, yet, in a minor way, can hold its own with fair credit. Several French gardens, moreover, have sprung up in various districts, and appear to be rendering a good account of themselves in their more special lines. Country people in the shires away from large towns are proverbially conservative in habit and slow to change their methods, hence Dorset, where we have no big cities, is perhaps—though not behind her immediate neighbours—hardly up to the mark in adopting up-to-date and, consequently, as far as the future is concerned, more profitable methods. I allude in particular to the lamentable number of "dead" or somnolent orchards, still so widespread throughout the county. Many of the wretched apologies planted years ago with the now unremunerative Eider Apple, are, in these latter days, quite past their best, and frequently derelict. One sighs to see these crowded groves of age-lent trees, covered with moss, thickets of branches intermingling one with another and

penetrating their neighbours, frequently with part of their limbs sprawling on the ground and their roots torn up and exposed to the air. Whatever fruit these wretched arboreal wastrels produce can be but immature, scabby, and unprofitable. Other grounds, of course, have been from time to time bettered, and newer varieties put in to fill up gaps, but this is done too often in a half-hearted manner. Even good, sound orchards have been frequently half-ruined by improper methods. I allude first and foremost, to the shocking damage done to pendent branches by pasturing horses or cows. These, from mischief or taste, not only nibble at and pull down all branches within reach, which leaves them (so far as they survive at all) bare of buds and foliage, but, by reason of their disastrous habit of biting at the bark, strip whole sides of the stem, thereby causing disease and premature decay, if not a very speedy decease. Pigs and sheep, or quite young calves seldom do any harm. It is odd that the owner of an orchard, be he farmer, cottar, or merely amateur, does not more often realise which way his bread is buttered. Take the case of any orchard with fair prospects and possibilities, it is surely simple enough to arrange its feed on satisfactory lines, and also to avoid the lamentable waste there is with Apples lying about for weeks as they fall in rank, sordid grass, valuable dessert and long-keeping cooking fruits alike, accumulating to rot and let their fellows bruise themselves as they, in turn, drop from the trees. It is surprising how many so-called fallings reach the ground originally perfectly sound, and only get spoilt subsequently. These, if collected every few days, and the better kinds carefully kept separate, especially after a heavy fall from a high wind, can be assorted and sold at three to six times the price they would fetch if badly garnered in and of necessity marketed either for low prices, or, in a plentiful year, found to be a drug in the market, and of use only for cider or even for feeding the pigs.

Then there is another waste with its consequent dire results, namely, that caused by not thinning out orchard trees frequently enough, for not only does it vastly improve the tree and its immediate fellows to let in light, air, and even frost, thereby sending it more completely to rest in Nature's sleeping period, but the very process of branch removal brings in an excellent source of firewood or its value in money. To be practical, the writer not long since indulged in one of these systematic-thinnings out which often seem advisable on taking possession of an orchard. Not requiring the wood obtained thereby, two goodly stacks, they were sold for a sovereign, the equivalent locally of the value of half-a-dozen bushels of fruit, to say nothing of the prospective good with regard to cleaner and finer fruit from the trees in a season or two. Orchard trees, especially when of full adult growth, will stand an immense amount of "stuff" being taken out of them, especially from the centre, an object ever in view being to keep the head open. Of course, straggling growers, such as Tom Putt and Wyken Pippin (how rarely one sees this excellent little pale-gold fruit outside Warwickshire and the Midland region), save all labour of this sort by their gaunt habit of growth.

Yet a third waste, akin to that just mentioned, consists in leaving old stumps or palpably worn-out veterans and dead trees to cumber the ground, instead of grubbing them up and turning them into firewood logs or posts. There, in nine cases out of ten, they remain to decay, and take up space which should be without loss of time allotted to young trees of the most up-to-date, profit-bringing varieties; yet it is probably not until a change of tenancy or ownership, that the needful reform is made.

Given sound culture and an avoidance of the above-stated delinquencies, I will now give my personal experiences, dealing more particularly with the grading of Apples and the right kind of markets, trusting that my conclusions, which are the result of some years' practical experience, may be of benefit to others, independently of the county in which the reader may chance to reside.

Presumably, one must go several decades back to find such a universally sparse fruit year as 1910, more particularly as to Plums, Apples, and Pears. For the deficient crops have been pretty widespread throughout the country, with merely local patches here and there, which, for some reason or other, did normally or even well. This being so, it has behoved those growing Apples for profit to consider more than their wont how best to market their reduced supply. In many parts, alas! this consideration was unnecessary, owing to the produce being not more than the owner himself could utilise. Disastrous tales reached me in the course of correspondence about my own Apples. One party stated that he himself was usually in a position to supply the trade, but that last season his two orchards were absolutely barren, with the exception of a few Eider trees. In September, in the Isle of Wight, very poor fruit was commanding 4d. per lb. which ordinarily should be selling at 1d., and a greengrocer was lamenting that some I was buying were the last Apples the farmer said he could let her have. A lady wrote me from Sussex that from 100 trees she had 60 Apples! While a clergyman in the west of England, who had for some years augmented his stipend by supplying, from his garden and glebe orchard, a dozen or so regular customers with a winter's store of Apples and Pears, had to disappoint them all, not merely these fruits failing, but also his Nuts and Medlars. The worst accounts seemed to come from Sussex, Surrey, and Hants., where, in most districts, the crop apparently was a failure. I cannot think that, though, of course, we had indolent crops, we in Dorset fared so badly. In my own case, though a large garden (one half four-walled), with pyramids, standards, and espaliers, was, with the utmost uniformity, barren, probably not half-a-bushel being produced by the lot and that from maidens, yet my orchard produced some 60 bushels, against 90 or so in the previous season. Indeed, out of about 85 trees, 20 bore a good or fair crop, while the remainder contributed a smaller or greater quota to the sum total, and, indeed, a sum comfortably in excess of last season's larger supply was obtained, as the result of the higher prices now obtaining. How far attentive cultivation was responsible for this fair crop I cannot, of course, say. The orchard is in no way remarkable, having been planted years ago with the

usual west country mixture of cider, dessert, and cooking Apples, but for several seasons the branch thinning-out process has been attended to with care. The best bearers were among dessert varieties; Cox's Orange Pippin, King Pippin, Fearn's, Stamford, and Cockle Pippins, the last two being heavy crops, while cookers that acquitted themselves well were Hoary Morning, Tower of Glamis, and Tom Putt. A seedling of Alfriston produced the heaviest and finest crop of the season. As to prices, locally, cider Apples last year fetched 2s. the sack, and this year 3s.; fallings, 6d. against 8d. a peck; and fair, ordinary Apples, 2s. 6d., against 3s. a bushel of 48 lbs. The trouble and time involved in picking and, to some extent, grading, make these prices really unremunerative. For several seasons, therefore, the writer has adopted a totally different plan. The fallings, and some of the earlier but less important varieties, such as the Codlin tribe, my gardener is allowed to sell at the local price, or just for what they will fetch, because storing these before a market elsewhere is found would mean a great loss in decay of fruit, but better fruits are sent elsewhere. *P. A. Carnegie-Cheales.*

(To be continued.)

FLORISTS' FLOWERS.

SWEET PEAS IN 1911.

THE present is the opportune time to sow Sweet Peas under glass. The up-to-date method of growing these popular annuals is to sow the seeds carefully in boxes or pots, and raise seedlings for planting out in April. The very best plan is to plant the seeds in boxes, covering very slightly the seeds of lavender, white, and primrose-coloured varieties. It is advisable to place the seeds at least 1 inch apart, so that the plants can grow till about 3 inches tall without getting drawn. A gentle bottom heat is desirable to assist germination, but as soon as the seedlings are well above the ground, the boxes should be moved into a cool place, and kept near the roof glass. When large enough (usually when about 3 inches tall), the young plants should be potted off singly into 60 (3-inch) pots, or transplanted into other boxes, putting them about 3 inches apart each way. Keep the plants in the same house—shading till established—for two to three weeks longer. Those varieties which are inclined to run up without throwing out growths near the base should be topped, i.e., an inch should be pinched right off the top of the plant, which will cause it to break out near the bottom. Some time in March the plants, whether in boxes or pots, must be removed to a cold frame and gradually hardened off for planting in the open on the first favourable opportunity in April.

The problem of what varieties to sow is a most important one, and its solution is rendered exceedingly difficult by the enormous number of so-called novelties that are being sent out, and by the same, or practically the same, varieties appearing under different names in different seedsmen's lists. Comparatively few growers want more than a dozen sorts, but all want these to be quite distinct. Many seedsmen recommend the selections given by the National Sweet Pea Society; but even these selections, excellent as they are, are getting too numerous, no fewer than 25 classes being given. The task of reducing some hundreds of varieties to 12 is admittedly a difficult one, but it must be done, and the following dozen will give most satisfactory results. They are all waved flowers. Nora Unwin, a pure white flower of beautiful form; Clara Curtis, primrose-coloured, the nearest to yellow in Sweet Peas; Elsie Herbert, a large, white flower, edged prettily with rose; Mrs. C. W. Breadmore, a creamy-buff ground, margined with rose; Countess Spencer, the first of the waved Sweet Peas, and a very beautiful, deep, bluish-pink flower; Mrs. Hugh Dickson, a

cream ground flower of the type of Countess Spencer, a fine novelty; Asta Ohm, a splendid lavender-coloured flower from America, of large size; Sunproof Crimson, the best red variety; Othello Spencer, a large, dark-maroon variety; Helen Lewis, a bright, orange-salmon coloured variety; Marie Corelli, bright rose colour; and Mrs. Andrew Ireland, a rose-pink and cream bicolor flower, and an extra fine decorative Pea, *A. B. C.*

TWO GARDEN-RAISED SNOWDROPS.

THE first of the two Snowdrops with which I propose to deal was sent to me some years ago by the late Mr. William Thomson, Auchinraith, High Blantyre, Lanarkshire. It was of his own raising, the parents being *G. nivalis* and *G. plicatus*,

drop, and the few friends to whom I have been able to give bulbs have been much pleased with it. The leaves, which are broadish and handsome, are plicate, and the large, well-formed flowers are borne on tall, stout stalks.

There are few Snowdrops which surpass *Galanthus Melvillei* major in beauty. This form (see fig. 19) originated at Dunrobin Castle, Sutherlandshire, and was named in honour of its raiser, Mr. D. Melville. The late Mr. James Allen classed it as belonging to the *Imperati* section, and in many respects it is like some of the varieties of this Snowdrop, which is, after all, only the southern form of *G. nivalis*. In appearance *G. Melvillei* major is a considerable advance upon the latter, being larger in all its parts, and producing a finer effect either when grown in the open or in pots. The

(Photograph by S. Arnett.)

FIG. 19.—*GALANTHUS MELVILLEI* MAJOR.

the only species he had in his garden. Some of the others sent at the same time are also very beautiful Snowdrops, selected with great taste and care, and almost every one showing traces of *G. plicatus* in the plicate leaves, which are such a marked feature of that fine species. The hybrids owe much of their charm, however, to *G. nivalis*, and among the few I have now, several having been lost when I removed to my present garden, that which I named Wm. Thomson a good many years ago, is by far the best for freedom of growth and general beauty (see fig. 20). It is a really handsome Snow-

bulbs are almost twice the size of those of *G. nivalis*, and the leaves are longer, broader, and of greater substance. The flower-stalk is frequently 2 or 3 inches taller. The flowers are more globular than those of *G. nivalis*, and they retain this shape when fully open to a greater degree. Their colour is a delicate, creamy-white, but not so pronounced in the creamy tint as to detract from the purity which is recognised as one of the attributes of the Snowdrop. It is, when established, a good grower, but it is frequently a few years before it shows its real vigour. *S. Arnett, Dunfries, N.B.*

THE ROSARY.

SOME VERY DARK ROSES.

BEFORE the planting season is over, a few comments upon the best of the deeply-coloured Roses may be of interest. The darkest we grow is Empereur du Maroc (1858), a seedling from Géant des Batailles. Roses which have given us very deep-coloured varieties are Eugène Appert and Abél Bramerel. Empereur du Maroc is a more vigorous grower than the other varieties just mentioned, and all are exceptionally early and brilliant bloomers. Empereur du Maroc is a deep velvety maroon, small, but well formed. The others are imbricated, or else shaped much after a Camellia blossom. My own choice as to the best dark Rose would be Prince Camille de

late in the season, while Louis Ricard is a mixture of deep vermilion and black, and does not burn in the sun—a great failing with many of our dark-coloured Roses. Commandant Felix Faure, and the newer variety Chat-au-de-Clos Vougeot, are two more, which are especially free from burning, both being good in every respect. Black Prince is a very deep blackish-crimson, hardy and free flowering. Fisher Holmes, Crown Prince, and Duke of Connaught are light velvety-crimsons, shaded with deep scarlet. I would have liked to include Dr. Sewell in this short list, but it is of moderate growth, and of little use after the maiden stage. A. P.

CRIMSON ROSES

CRIMSON Roses are of the greatest possible value for garden ornamentation. Some of the

and always a supreme favourite of his, is still an effective garden and exhibition Rose. Crown Prince and Black Prince, in virtue of their attributes of colour and perfume, also still survive. I have always regarded A. K. Williams as more reliable in the autumn than in the early summer months, when the flower-buds occasionally do not open with perfect facility. It is undoubtedly a brilliant exhibition Rose. Almost equally decorative are Alfred Coburb and Dupuy Jamine. Horace Vernet and Victor Hugo, H.P.'s, which, at their finest, are extremely beautiful, require a warm season and a fertile soil. Two of the most effective and reliable of modern crimson varieties are Hugh Jackson and Captain Hayward, and the former is perhaps the more perfect of the two. Both have grand attributes of colour, form, fragrance, and very vigorous growth, and they are therefore quite invaluable for garden cultivation. Duke of Edinburgh and Duke of Teck, both of which originally emanated from Cheshunt, are Roses whose lovely colours have not yet been surpassed, though other varieties, of approximating complexion, may have larger flowers. Lady Helen Stewart, the colour of which may be described as bright crimson, with scarlet suffusion, is an exquisite Irish Rose. Two of the finest Roses sent out by Messrs. B. R. Cant & Sons, of Colchester, are Prince Arthur, of fascinating hue (probably a derivative from General Jacqueminot or Duke of Edinburgh), and Maharajah, a magnificent variety with enormously large, single, dark crimson flowers. Another highly attractive and strong growing Rose of an almost similar character, and not less fascinating in bloom and radiant foliage, is Barton Job. Commandant Felix Faure, a Rose of more compact and fuller character, is a dark variety of distinctive aspect, which I have often found of quite commanding beauty, especially at exhibitions. Warrior, described by the raisers as "blood red colours in bud, with the opening flowers vivid scarlet-crimson," is very floriferous, and a fine autumnal bloomer. A grand Irish Rose is J. B. Clark, bright crimson with a very distinctive Plum suffusion. The flowers are fragrant and often enormously large. It is a glorious grower, with splendid petals. Among semi-climbing Roses some of the finest are Crimson Rambler and Craniole Superieure. Hiawatha, Carmine Pillar, and Aris Rover are also of supreme value for garden decoration. David R. Williamson.

HYBRIDS RAISED AT KEW.*

Continued from p. 19.

Musa kewensis (M. Mannii × M. rosacea).—This hybrid was produced in 1895. It has slender "stems" 3 feet high; leaves 3 to 4 feet long, 6 to 10 inches broad; inflorescence a short spike, with decorative bright crimson bracts 4 to 6 inches long. Flowers in threes in the axils of each bract with a cream coloured calyx and white petals. It flowered in 1895 and was figured for the Kew collection of drawings.

Nymphaea kewensis (N. Lotus var. alba × N. Japonica).—Raised in 1895; flowers large, 6 inches in diameter, with rose-red petals and golden-yellow stamens. Habit as in N. Lotus. N. Devonensis itself is, by some botanists, referred to N. Lotus; others consider it to be a hybrid between N. rubra and N. Lotus. N. kewensis is figured in the *Botanical Magazine*, t. 6938.

Primula kewensis (P. floribunda × P. caucellata).—This hybrid appeared as a chance seedling among a batch of P. floribunda in 1899. It was exhibited at the meeting of the Royal Horticultural Society, February 27, 1900, and was awarded a First-class Certificate. (See the *Gardeners' Chronicle*, 1900, xvii., pp. 150, 195, fig. 63; *Gardeners' Magazine*, 1900, 252, with figs.) During the summer of 1900 the supposed parents were artificially crossed, and good seed was obtained from P. floribunda; a proportion of

* Reproduced from *Kew Bulletin*, N. 9.

FIG. 20.—GALANTHUS 'WILLIAM THOMSON' (G. FLICATUS × G. NYVALIS).

Rohan (1861), a deep, velvety-crimson maroon. There are few better doers than this variety, and it flowers very freely, but unfortunately it is one of the worst with me as regards mildew; La Rosière and Jubilee are synonymous with Prince Camille de Rohan. There are several good, dark varieties with a purplish-red tinge that are very effective, such as the glorious shades found in Abel Carrière, Victor Hugo, Charles Lefebvre, Xavier Olibo, and Louis Van Houtte, but the last two, with Horace Vernet, are indifferent growers. Jean Souper is a very deep, velvety-purple flower, and is especially good

oldest varieties are still among the most valuable for hedging or massing purposes. Among the most venerable of these is General Jacqueminot, introduced by Roussel, a French Rosarian, as far back as 1855, a Rose of rich colour and splendid fragrance, though not perhaps of such imposing dimensions as some of its successors. Charles Lefebvre (Lacharme, 1861), a Rose which has lived long enough to survive many others of similar colour, and of more recent origin, is still a supreme favourite with Rose cultivators. Beauty of Waltham, a variety of exquisite carmine hue, raised by the late Wm. Paul in 1862,

the resulting plants proved to be true *P. kewensis*. During the summer of 1910 the following crosses were again made:—

- No. 1. *P. verticillata** × *P. floribunda*.
- No. 2. *P. floribunda* × *P. verticillata*.
- No. 5. *P. verticillata* × *P. floribunda* var. *isabellina*.
- No. 4. *P. floribunda* var. *isabellina* × *P. kewensis* (type).
- No. 5. *P. floribunda* var. *isabellina* × *P. kewensis* (seedling form).
- No. 6. *P. kewensis* × *P. floribunda* var. *isabellina*.

All the above crosses produced good seed with the exception of No. 6. No. 1 produced a quantity of what appeared to be good seed, but only a few plants have been raised; so far they are all unflowered.

Rehmannia Briscoi (*R. Henryi* × *R. unguicula*).—This cross was made in 1908, the plants flowering in 1910. *R. Briscoi*—raised by Messrs. J. Veitch & Sons, and figured in the *Gardeners' Chronicle*, 1910, xlvii., 133—is the result of the reverse cross. The colour of the flowers is the same in the two hybrids, but the influence of *R. Henryi* is more marked in the Kew plant, in that it produces more numerous flowering growths from the base compared with the specimens of *R. Briscoi* produced by Messrs. Veitch. So far all attempts to fertilise the Kew hybrid either with its own pollen or that of either of the parents have proved abortive.

Rehmannia (*R. Henryi* × *R. glutinosa*).—A few plants have been raised this year but as yet have not flowered.

Rhododendron kewense (*R. Griffithianum* × *R. Hookeri*).—Crossed in 1874; flowered in the Temperate House in May, 1883. It has proved to be hardier than either parent, plants having withstood several winters in the *Rhododendron* Dell at Kew. It forms a sturdy, much-branched plant, with leaves 6 to 10 inches long by 2 inches broad; the flowers, which are disposed in a large, loose truss, are broadly campanulate, 3 inches across by 2 inches deep, of a pale flesh colour, the unexpanded buds being a deep rose. (See *Gardeners' Chronicle*, 1883, iii., 620, and *The Garden*, 1882, xliii., pl. 385.)

(To be continued.)

ORCHID NOTES AND GLEANINGS.

DENDROBIUM GOLDIEI

The illustration in fig. 21 is reproduced from a photograph supplied by Mr. C. F. Karthaus, Orchid Nursery, Potsdam, who states that the plant which it depicts was imported with *D. superbiens*. Mr. Karthaus suggests that it is a natural hybrid between *D. superbiens* and *D. bigibbum*. In his original description in the *Gardeners' Chronicle*, 1873, i., p. 652, the late Professor Reichenbach gave a long account of his experience with *D. Goldiei* in Mr. B. S. Williams' Nursery at Upper Holloway, but left some points undecided. Later he referred to it again, mentioning some differences between it and *D. superbiens*, which characteristics, however, may not be constant. Other authorities place it under *D. superbiens* as a variety.

It is strange that the presence of two forms is always noted when *D. superbiens* is imported in considerable quantities. Usually the name *Goldiei* is given in gardens to the best and showier form, although the description points out that it is rather smaller and has narrower petals.

It is a very pretty and floriferous species, lasting in bloom for months. It should be grown in a warm, moist house with *D. Phalenopsis* and *D. bigibbum*, suspended from the roof when possible. After the growths are fully made up, a restricted supply of water and a few degrees lower temperature should be given until the growing time comes again, but the plants should never be placed in a cold house at any season.

* *P. verticillata* was also emasculated and carefully protected without being fertilized, and no seed was formed; the experiment was made in order to see whether ovules might not be produced by vegetative means.

AMERICAN HAWTHORNS.

SOME NEW ARBORESCENT SPECIES.

(Concluded from page 17.)

CRATEGUS FERTA.—This Hawthorn is occasionally a tree 18 feet or more in height, with a trunk 4 to 6 feet long and 8 to 10 inches in diameter, and with large, flat, spreading branches, forming a compact, broad head. The leaves are elliptic to obovate, cuneate, and much narrowed at the base, 2½ inches long and 2 inches wide. The 20-stamened flowers, with creamy-white anthers, are borne on long, slender, villose pedicels, depending from lax corymbs, the time of flowering being about June 10. The roundish to sub-globose, scarlet

3¼ inches wide on young shoots, and very thick and coriaceous. The 10-stamened flowers, with cream-white anthers, are produced in large, compound villose corymbs, and expand about May 28. The species is one of the earliest of the *Tomentosa* group to flower in Western New York. The roundish, pea-shaped, crimson fruits are suspended in loose, drooping, villose clusters, and ripen about the middle of September. They assume a distinctly reddish colour about August 30. The type plant grows in heavy clay soil on the banks of the Genesee River, Genesee Valley Park, Rochester, N.Y. It is a common and widely-distributed species throughout Western New York and Ontario, Canada. In its showy flowers, lustrous green leaves, and

FIG. 21.—DENDROBIUM GOLDIEI: FLOWERS, DEEP PURPLE.

fruits are produced in clusters, and ripen about the end of September and beginning of October. The type tree grows at the side of the Grand Trunk Railroad, at the junction of King and Queen Streets, Toronto, Canada, and so far the species has not been reported outside that region.

C. FERENTARIA.—When this species was first described, it was only known as a much branched shrub, but I have often found it during the past few years with the habit of a small tree, 15 feet to 18 feet in height and with a clear, stout stem. The branches are horizontal, slightly ascending and intricate, forming a dense, round-topped head. The leaves are often oval on young shoots, and on fertile shoots are rhombic to obovate, and rounded at the base, 4 inches long,

conspicuous clusters of scarlet fruits, it forms a fine, ornamental garden tree.

C. FINITIMA.—A slender tree from 20 feet to 25 feet high, with large-spreading branches, produced sparingly, the lower ones being horizontal and drooping, and the upper ones ascending, and tapering very gradually to the petiole, 5 inches long and 2¼ inches wide. The flowers have 20 stamens, with pink anthers, and slender tomentose pedicels. They are produced in many-flowered corymbs about May 30. The sub-globose fruits, of lustrous orange red colour, have a prominent calyx, and ripen about October 1. The type tree grows at Niagara Falls on the New York State Reservation, and near to the American Falls. Whilst visiting

Niagara Falls last June with Mr. W. J. Bean, Assistant Curator of the Royal Botanic Gardens, Kew, I pointed out to him the type plant of *C. finitima*, and he was much interested in its characters.

C. FULGIDA.—This species forms a stout arborescent shrub, with sprouting and ascending branches, making an irregular-shaped head. The leaves are oval to obovate, and narrowed at the cuneate base; often 4 inches long and $3\frac{1}{2}$ inches wide. The 10-stamened flowers, with cream-white anthers, are borne in stout, densely villose corymbs about June 4. The sub-globose, dark crimson, partially transparent fruits ripen in clusters about the end of September. The type plant grows at the side of the Grand Trunk Railroad, at the junction of King and Queen Streets, Toronto, Canada. This Hawthorn appears to grow in gregarious masses, and is well distributed throughout Ontario. I found it abundant at Bellville, on the Bay of Quinte,

The type tree grows in Grand Rapids, Michigan, and is a common species in Michigan, Western New York, and Ontario, Canada.

C. GLABRATA.—A very tall, arborescent shrub, seemingly gregarious. When crowded together the plant grows to a height of 25 feet, with numerous ascending branches, forming an open head, but in cultivation it would probably become much more tree-like. The leaves are broadly ovate to obovate, abruptly rounded at the base, 5 inches long and $2\frac{1}{2}$ inches wide. The flowers have 10 creamy-white anthers, produced in large, almost glabrous corymbs, and open about May 30. The sub-globose, lustrous scarlet fruits marked with small yellowish patches, ripen about the middle of September. The type plant grows in a thick group of the same species at Bracondale, a suburb on the north side of Toronto, Ontario, Canada. The species has not been recorded outside the environment of Toronto.

sub-globose, dark orange-red fruits ripen about the beginning of October. The calyx lobes are usually spreading, not reflexed and appressed to the fruit as is generally the case in most of the *Tomentosa* species of *Crataegus*. The type plant grows on the banks of the Genesee River in a heavy clay soil and in Genesee Valley Park, Rochester, N.Y. Only two plants are known of this species in a wild state. The specific characters are quite distinct, and readily noticeable, and the seed germinates readily. Its scarcity as a wildling is surprising, but it will undoubtedly be discovered in some other habitat in the near future. This is another species named in compliment to Mr. C. C. Laney, the superintendent of the Rochester Parks.

C. PICTA.—This plant forms an arborescent shrub 15 feet to 18 feet high, with spreading, but mostly ascending branches, with an upright, compact head. The leaves are ovate, and on young shoots are often oval, rounded at the base, 3 inches long and $2\frac{1}{2}$ inches wide. The 10-stamened flowers, with cream white anthers, are borne in smooth corymbs, or nearly so, and open about June 4. The sub-globose, scarlet fruits, with a very prominent calyx, ripen about October 1. The type plant grows at Bracondale, a suburb on the north side of Toronto, Ontario, Canada. The foliage bears a general resemblance to that of *C. Dumbari*, a species of a closely allied group.

C. STENOPHYLLA.—A tree about 18 feet high and wide spreading branches, forming a broad, compact head. The leaves are oval to obovate, rounded, and gradually narrowed at the base. The stamens, which number 20, have anthers a dark rose colour (an unusual colour in the *Tomentosa* species). The blossom appearing about June 4. The short, oblong, orange-red fruits on sparingly fruited, hairy corymbs ripen during the first week in October. The type tree grows in the Black Creek Flats on the west side of Toronto, Ontario, Canada, and is at present known only in that locality.

C. STRICTUS.—This species forms a tree 20 feet high, with spreading and ascending branches. The tree has often a clear, tall stem, which is usually covered with numerous long, compound, persistent spines. The leaves are oblong-ovate to obovate, and usually quite narrowed at the cuneate base. The 20-stamened flowers, with cream-yellow anthers, are produced in densely tomentose corymbs from June 10 to 15. The species being one of the latest of the *tomentosa* group to bloom. The obovate fruits are much narrowed at the ends, and ripen about the middle of October. They are orange-scarlet, and the calyx lobes are much reflexed and oppressed. This species was described by Mr. W. Ashe, but I do not know where the type plant grows. It is, however, a common species in Western New York and Pennsylvania, and throughout Ontario, Canada. In its thin obovate leaves and obovate fruits it bears a general resemblance to *C. tomentosa* of Linnaeus. It is a species to be highly commended for garden decoration.

C. VENUSTULA.—An arborescent shrub 12 feet to 15 feet high, with erect, slender stems, forming a thin open head. The leaves are oblong-ovate, rounded and gradually narrowed at the base, 3 inches long and $2\frac{1}{4}$ inches wide. The 10-stamened flowers, with cream-white anthers on glabrous corymbs, or nearly so, are produced about May 30. The sub-globose, scarlet fruits, with prominent calyx, ripen about October 1. The type plant grows in the city of Niagara Falls, and is found throughout Ontario, Canada. When I first found this species in 1902 at Niagara Falls, I was somewhat puzzled for a short time with what appeared to be two distinct types of flowers on the same plant. On close investigation I found two species closely united on what was practically one stem. The other species was *C. leiophylla* in an entirely different group. Seeds of the two species had evidently germinated together. *John Dunbar*.

FIG. 22.—*CRATEGUS GEMMOSA* FLOWERING IN GENESEE VALLEY PARK, ROCHESTER, U.S.A.

Ontario, Canada. Its brilliant, crimson translucent clusters of fruits are very handsome.

C. GEMMOSA (see fig. 22).—This is one of the tallest growing of the *tomentosa* group, and in some conditions forms a handsome tree over 50 feet high, with stout-spreading and ascending branches, forming a broad, somewhat open and well-balanced head. It forms a well-defined, tall trunk, 12 inches in diameter at the base. The leaves are usually broadly oval, and on fertile shoots occasionally broadly obovate and rounded at the base. The 20-stamened flowers, with rose anthers on slender pedicels, form densely villose, many-flowered corymbs, blossom about June 1. The lustrous scarlet, short, oblong fruits, very succulent when fully ripe, mature about October 1. The calyx lobes are much reflexed and appressed to the sides of the fruits, but that in varying degrees is more or less characteristic of most of the *tomentosa* species. *C. gemmosa* is very noticeable in winter with its large brownish buds.

C. HONEYENSIS.—An arborescent shrub about 14 feet high, with distinctly ascending branches, forming an almost fastigate habit. The leaves are ovate to obovate, abruptly narrowed at the rounded base. The 20-stamened flowers, with pale pink anthers on drooping villose pedicels, are produced on large corymbs about May 30. The ovate, scarlet fruits ripen about the end of September. The type plant grows on the west side of Honeye Lake, Ontario County, N.Y., and is found in the adjoining Livingston County, around Hunlock Lake.

C. LANEYI.—This species forms an arborescent shrub from 12 feet to 15 feet tall, with a slender, branching habit. The growths are spreading and ascending, forming a broad, open head. The leaves are oval to oblong-ovate, rounded and tapering at the base, and often somewhat decurrent on the petiole, 3 inches long and $2\frac{1}{2}$ inches wide. The 12-15-stamened flowers, with cream-white anthers, on many-flowered villose corymbs. The time of flowering is about June 5. The

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. Hoi Ford, K.C.V.O., C.I.E., Westonbirt, Gloucestershire

ROOTING MATERIALS.—Most Orchids, when growing naturally, have their roots in a great measure exposed to the air on trees and rocks to which they cling, with the head of the plants extending to the light, and generally where decomposed vegetable matter has accumulated within reach of their roots. It is obvious, therefore, that, if the roots of such epiphytes are potted in a compost which is at all adhesive, they will very soon perish; at the same time, loosely-potted plants do not grow so strongly as when a more or less substantial material is employed and firmer potting practised.

OSMUNDA AND POLYPODIUM FIBRES.

English peat of the best quality for epiphytal Orchids is now almost unobtainable in large quantities. From the early 'nineties there has been an increasing scarcity of this material, but it is only about 10 years since Osmunda fibre from America and Polypodium fibre from the Continent have been proved to be satisfactory substitutes. These materials have gradually found favour, and are now extensively used as a rooting medium for Orchids. When purchasing these materials it will be found most profitable to select the best qualities obtainable, as the more durable the fibre the cheaper it is in the end. Immediately a consignment arrives, the fibre should be turned out from the bags and spread loosely on shelves in a dry but well-ventilated store-room, and, if it is kept in stock for a considerable length of time, it should be turned over occasionally. Another important matter to bear in mind is that these materials sometimes get damp through the action of sea water during their journey to England, and that the use of any affected in this manner would cause serious injury to the plants. It follows that the supplies should be obtained from reliable firms that may be trusted to destroy consignments which have suffered in this way.

SPHAGNUM-MOSS.—A good supply of Sphagnum-moss should be got into stock, as in the event of severe and protracted frost the moss sometimes gets so far killed or injured as to reduce it to a slimy mass, unfit for use. When it is received it is advisable to pick out all rubbish and particles of grass that are found frequently amongst it, for if grass and weeds are used in a living state, they may grow in the pots and take a good deal of trouble to eradicate. The best plan for storing this material is to spread it out thinly on a boarded floor and to turn it occasionally until it is quite dry. A sufficient quantity of turfy loam of a not-too-sandy description should also be procured and stacked in a dry place ready for use. In addition to the materials already mentioned, some wire suspenders, teak-wood baskets, clean pots and pans, crocks and charcoal should be got ready for use in order that the work of potting may not be delayed in the busy season.

CŒLOGYNE CRISTATA.—The plants of *C. cristata* should never be allowed to become quite dry during winter, sufficient moisture at the roots being needed to preserve the pseudobulbs in a perfectly plump state until the flowering stage is passed. These plants are best kept during winter in a cool intermediate house, and, if there is a sufficient stock of plants, a few may be placed at intervals into warmer quarters to prolong the season of bloom.

ZYGOPETALUM MACKAYI.—The flowers of this most useful winter-blooming Orchid last many weeks in perfection. They are admired for the pretty blue of the broad, handsome labellum and the more sombre brown and yellow of the sepals. The cultivation of *Z. Mackayi* is not difficult, provided that the plants are kept clean. The soft foliage and bulbs are apt to be attacked by a brown scale insect, which, though it may be easily destroyed, is sure to leave its mark on the plant if the infestation has been severe. The rooting materials should always be kept somewhat moist. The flower spikes appear from the centre of the

young growths, and as the plant is therefore flowering and growing simultaneously, it needs moisture notwithstanding the fact that the weather at the time is often cold and dull. *Z. Mackayi* thrives best in a moist atmosphere of intermediate temperature, and, when actively making its growth, the plant should be afforded abundance of water at the roots. It dislikes root disturbance, and is one of those Orchids which, if they once get into an unhealthy condition, are improved only with very great difficulty. The rooting medium should be composed of fibrous loam, two-fifths, and leaf-soil, turfy peat, and Sphagnum-moss, one fifth each. This compost should be made more porous by the addition of coarse sand, crushed bones and charcoal.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

CINERARIAS AND HERBACEOUS CALCEOLARIAS.—These plants are, in many establishments, grown in heated frames, and are placed on a layer of cinder ashes that is kept moist. No better accommodation can be afforded these subjects, for they can be kept close to the glass, and yet ventilated freely in suitable weather. See that these moisture-loving plants do not suffer for want of water, especially when the pipes are heated. Watch closely for aphides, and if any are detected fumigate the pit cautiously. When a favourable occasion occurs, it is well to take the plants out of the pit and to rake over the layer of ashes. Keep a watch for slugs, which may be resting upon the pot or sometimes even on the under surfaces of the leaves. When fire-heat is needed in the pits be extremely careful not to use it excessively, for even with a covering on the glass at night the temperature should not exceed 40°.

PRIMULAS AND CYCLAMENS.—Chinese Primulas, both single and double flowered, will be better in a drier atmosphere than that which Cinerarias enjoy. Backward or small plants not yet advanced to the flowering stage, may be placed in a pit or greenhouse slightly warmer than the cold greenhouse. By a pit, I mean a span-roof structure with a path through the centre; such structures are extremely useful, both in large and small gardens. For the Primulas and also for *Cyclamen persicum*, I advise a temperature of about 5° higher than that maintained in the cold greenhouse at this season, always ventilating freely, but with caution, when the weather is favourable. If necessary, Primulas and Cyclamens may be successfully grown upon shelves in the greenhouse, where they will enjoy a free circulation of air. *Primula obovata* may also be grown upon shelves. Guard against damping in Primulas, being careful to remove old flowers before they decay, and not to pour water directly upon the crown of the plant. Plants of Primulas and Cyclamens about to flower may be given an occasional dose of weak liquid manure procured from a reserve tub in which none of the sediment has been disturbed.

FORCING PLANTS.—The forcing of plants comes under two heads. First, the forcing of plants for supplying flowers, and, secondly, plants for use in the conservatory and indoor decoration. Those plants intended merely for supplying flowers may be small in size, and yet yield a good quantity of blooms, but the larger plants often stand the decorator in good stead for use in the conservatory and for massing. It is very convenient if, at this season of the year, a small house or pit can be set apart for the purpose of forcing, as the makeshift system of placing the plants in all sorts of places is never satisfactory. Due care should be taken to see that no plants are forced too hurriedly, especially in the early stages, as spindly, much elongated growth is undesirable, and the flowers of Rhododendrons and Azaleas produced in great heat are not durable. The value of slow forcing is especially obvious in the case of plants for placing in the conservatory, where the presence of permanent plants prevents the employment of extra warmth. All forced plants used for such a structure should first be kept for a few days in an intermediate temperature. Some plants may be removed from the forcing house when the flower buds are only just expanding, for example, early Daffodils, Hyacinths and Tulips may be used for decoration when the earliest flowers are scarcely open, but Lilies of the Valley, Lilacs and

Spiraeas should be more advanced. Hardy shrubs should be provided with plenty of atmospheric moisture during forcing, and if the pots are plunged in a bed of leaves, so much the better, whilst a liberal use of the syringe is also desirable. For early forcing, be careful to select the most reliable kinds, namely, those that are known to respond most readily to a moderate degree of warmth. Amongst Azaleas, the varieties *Deutsche Perle* and *Narcissiflora* are two of the best whites, whilst *President Oswald de Kerchove* as a salmon tinted, and *Simon Marbler* as a rose-pink flower are both excellent. Of Rhododendrons use such as *Early Gem*, a rosy-lilac flower and a most compact plant, and *R. Nobleanum*, which needs scarcely any forcing to induce it to flower in February. Of Lilacs, *Charles X.* is still one of the best as a decorative plant when in flower. If required for cutting purposes only, then larger bushes of Lilacs may be lifted from the open and brought inside. These flower very quickly if kept in the dark and syringed frequently. Both Lilies of the Valley and Spiraeas should have the crowns covered with cocoa-fibre to induce an early start. The retarded crowns of Lily of the Valley will still for a few weeks give better results than new crowns. Of such things as Daffodils, Tulips and Hyacinths it is preferable to introduce frequent small batches than larger batches and incur the risk of a break in the supply. Most of these bulbs should now be generally overhauled to see that too much progress is not made before they are removed, from the ashes, and to see that they are not injured by frost.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

STRAWBERRIES.—A good dressing of half-decayed stable manure will protect the plants from severe frosts and cold winds, and will also provide a foundation for the summer mulch applied when the fruit is ripening.

GOOSEBERRIES AND CURRANTS.—The bushes may be pruned now, although many growers defer the operation until later, as the branches provide some protection against Bullfinches and other birds during the latter part of the season. But birds may be kept in check by the use of one of the many spraying solutions sold for the purpose. Early pruning permits of the surface soil immediately under and around the bushes being loosened, thus allowing frost to enter and destroy hibernating insect pests. I have often noticed that where early pruning is practised, the Gooseberry caterpillar does not appear in such numbers the following season.

WALL FRUIT.—Continue the pruning, nailing or tying in of wall trees during open weather. If the ground has been properly prepared, as advised in a former Calendar, all kinds of wall trees may be planted in the absence of frost. If the soil is a rich, strong nature, little or no manure is needed, but if it is light, with a porous sub-soil, then the addition of a suitable manure is essential. In planting the trees on heavy, strong soils, it is advisable to keep them a little higher than the general surface of the soil; this gives them a decided advantage in the formation of surface roots, especially if the sub-soil is of a like heavy nature; in a light soil, on the contrary, it is better to plant them on the level, or even a little below the level of the surface, so that all the natural moisture available may more readily reach the roots. Where the walls are covered with wide glass, or other coping, the soil should be examined carefully to see that it has not become in the least degree dry. This advice may seem superfluous after the heavy rainfall of 1910, and during the present month, but it is surprising how large is the amount of moisture an ordinary coping will keep off the borders, and especially that portion of the soil in close proximity to the wall, which is always the driest portion. Some growers advise the application of liquid manure during the winter months, under the conditions just named, but I have frequently noticed that, after such treatment, the surface soil is apt to become sour, particularly if several dressings are given. Beyond this, the trees are encouraged to make too strong a growth during the early part of the season; possibly the one exception may be Pears that are worked on the Quince stock; these seldom make strong wood being surface-rooting plants.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, K.T., Tynninghaime, East Lothian.

FRAMES.—Most of the hardy bedding plants in cold frames will need rather more ventilation after this date, in order to prepare them for the complete withdrawal of the lights during favourable weather in the course of a few weeks. The choice, named varieties of Pentstemons now in cutting-boxes or dibbled in beds of soil may be transplanted into 3-inch pots shortly after they have made roots. Antirrhinums which have made roots may be topped to induce the production of lateral shoots from near the base. Chrysanthemums in boxes may be transferred to one of the glasshouses, where they will produce sucker growths suitable for cuttings. If the supply of tall Lobelias needs to be increased, the plants should also be shifted into warm quarters. Sometimes losses are experienced through damping; therefore, until new roots are plentiful, care must be exercised in affording water.

CALCEOLARIA.—*C. amplexicaulis* may now be potted up singly from the cutting boxes. Chrysanthemums being nearly over, there is room for the Calceolarias and other plants requiring immediate attention. The smallest pots that may be used satisfactorily are 5-inch pots. Directly a plant is potted it should be supplied with a 12-inch long stake, to which the growth should be secured. One-year-old plants will grow rapidly if given liberal treatment and if care is taken to secure the growths to stakes. *C. Burbidgei* requires rather more rooting space than *C. amplexicaulis*, but in other respects the treatment is similar.

PÆONIA.—The tree Pæony (*Pæonia Moutan*) in its splendid varieties needs the dead points of last year's shoots cut back to the first strong buds which are now swelling, and the larger bushes should be examined for weak shoots, which should be cut out. Whether the tree Pæonies are worked upon other tree Pæonies or a stock of the herbaceous Pæony, suckers are equally liable to appear. These should be removed directly they are observed. If the herbaceous Pæonies were not manured after the decay of their leafage last autumn, manuring should be carried out without delay. The surface soil should be removed from about the roots and a thick dressing of rotted manure spread evenly all round them; then the surface soil should be returned, and if it is of a very porous description it should be compressed by treading. The dressing will act not only as a stimulating food, but it will also enable the plants, at least in the more northern counties, to produce their harvest of bloom without having to be watered. The present is not a suitable time to divide large plants. These should be left until after the flowering period, when they may be divided and replanted.

THE ROCKERY.—Many close-growing plants lose some of their shoots in the winter, and these must be removed to prevent the mischief spreading. Not a few plants, too, spread beyond their proper limits, and have to be curtailed. In the case of dwarf-growing plants, pieces should be pulled away, but with sufficient subjects the knife must be used. Still, by cutting more of the underlying than the overlying shoots it is possible to reduce the plants without making them appear unsightly for weeks afterwards. A slight sprinkling of very fine soil will freshen bare places on the rockery that later will be furnished with bulbous species. Most dwarf plants will appreciate this top-dressing, and the particles of fresh soil will be washed out of sight by the first heavy shower.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. Vicar of Giers, Aldenham House, Hertfordshire.

STRAWBERRIES.—Batches of Strawberry plants should be introduced into the houses at intervals. Examine the drainage of every plant and wash the pots, removing any rubbish from the plant or surface of the soil. Shelves near to the glass in the various fruit-houses provide excellent positions for forcing Strawberries, the coolest houses being used for the latest plants. Water sparingly for a time, carefully examining each pot. Syringe both the plants and their surroundings, and, until the earliest flowers are set, make no attempt to hurry the plants by hard forcing. Gradually thin out the fruits to

four or five on each plant, and afford support to the trusses early by using small forked sticks or brushy twigs. Pinch back all runners, give occasional applications of manure water, and do not allow the plants to suffer for want of water.

MELONS.—If not already done, seed should now be sown for the earliest crop. Place one seed in a 3-inch pot in a mixture of loam and leaf-mould, which should be in a moist condition at the time it is used. Plunge the pots to the rims in a forcing-house, and cover each pot with glass. When the seeds have germinated, remove the pots to a position near to the roof glass.

FIG TREES IN POTS.—For producing an early supply of fruits, the cultivation of Fig trees in pots is preferable to the forcing of permanent trees. If the pots are plunged to the rims in a bed of leaves—preferably of Oak or Beech—and bottom heat from hot water pipes is provided, there will be little difficulty in getting the trees to break freely. Maintain a moist atmosphere by damping down frequently, and syringe the trees with tepid water twice daily when the weather is favourable. A night temperature of from 55° to 60°, according to the weather conditions, will be suitable. Afford water to the roots with care, and, as growth advances, give weak liquid manure at intervals, and also some reliable artificial fertiliser. Admit fresh air on favourable occasions, but close the ventilators again early in the day. Examine the growths frequently, and remove the weak ones and those that cause overcrowding. Stop the growths after three or four leaves have formed. Keep a sharp look out for red spider; should traces of this pest appear, sponge the foliage carefully with a suitable insecticide. Stir the surface soil in the pots at intervals, and keep the soil in the pots and bed free from weeds.

PERMANENT FIGS.—Complete the pruning of the trees as soon as possible. If the growths have become crowded, thin out some of the old wood, cutting at the base of the shoots, but taking care to leave sufficient young branches to clothe the lower parts of the tree with foliage and provide fruits for future seasons. Regulate the young growths, tying them as neatly as possible with strong strands of raffia, taking care not to make the tie too tight. For securing the larger branches use thin tarred twine. If the borders are found to be dry, give a good soaking with clean water, after first removing the surface soil and rubbish, and then add a top-dressing of chopped loam, lime rubble and wood ashes. When the house is ready to commence forcing, close it, but use no fire-heat for the first week, giving fresh air liberally when the weather is mild or bright. Afterwards maintain a temperature of about 50° at night-time, varying according to the weather, but do not employ fire-heat to exceed this degree of temperature for a time. Damp the paths and borders frequently, and syringe the trees with tepid water on fine days.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

TOMATOS.—Seeds should now be sown and placed on a gentle bottom heat until the young plants are well above the soil, when they should be placed near to the glass, in order to promote a stocky growth. When the plants are large enough to handle, pot them singly into small pots, using a compost of finely-sifted loam and leaf-soil in equal parts. October-raised plants, if not already potted, should be attended to at once, potting them moderately firmly in good turfy loam and leaf-soil, leaving a space of a few inches in each pot, to be filled by top-dressings at some future date. If possible, these early plants should be stood on a gentle hot-bed to promote root action, allowing sufficient air to keep them from becoming drawn. Place a stake to each plant as soon as it is potted, and afford water with care.

EARLY PEAS.—If room is not available in pits for raising young Peas for planting out, a sowing should be made on a warm border as soon as possible. The soil for this purpose should be light and rich, and the seed should be sown in trenches, the soil from which may be laid up on the colder side of the row to protect the young plants from cold winds, which often prove more harmful than

a few degrees of frost. Some varieties are harder than others, and no sort should be sown in quantity at this early date that has not been tested or recommended for the purpose. On January 2 we sowed one bushel of seeds of *The Pilot*, and hope to gather pods from the plants early in June. The same variety was sown last year on January 8, and we commenced gathering on the 10th of June. The seed should be covered with 2 inches of sandy soil, either from the bed in which they are sown, or old sifted soil from the potting shed. If pots and space are available, a small sowing of Peas may now be made to afford an occasional dish through April. There are many good dwarf varieties to choose from, *Harbinger* and *Chelsea Gem* being reliable sorts, and, if space will permit, *Early Giant* may be included. Sow the seeds in good, turfy loam, such as may have been saved from a Melon bed, mixing a little well decomposed farmyard manure with it. Peas in pots must never be subjected to much heat, nor be allowed to suffer from want of water.

EARLY CAULIFLOWERS.—Seeds of Cauliflowers should be sown at once, if not already done, and germinated in a temperature of 50°. When the young plants have made their first rough leaves, they should be pricked off at a distance of 4 inches apart each way in boxes, or they may be potted singly into small pots. In either case they should be placed close to the glass, in order to promote a sturdy growth. Ventilation should be given carefully until the plants are well established, but afterwards they should be hardened gradually, so as to be ready for planting permanently by the beginning of April. Varieties, such as *Early Forcing* and *Magnum Bonum*, should be sown at this date. Autumn-sown Cauliflowers in frames should be freely aired during mild weather, and those potted early in the season must not be allowed to suffer from lack of nourishment through being pot bound, but must be watered freely with liquid manure. It may even be necessary to afford larger pots to avoid premature "bolting."

LETTUCE.—Seeds of this salad should be sown thinly in boxes, and covered lightly with fine soil. Fresh air should be given freely as soon as the young plants appear, or they may become drawn.

PUBLIC PARKS AND GARDENS.

By A. J. ATLSOR, Superintendent of Public Parks, Leeds.

FLOWER BEDDING.—In my previous Calendar I emphasised the value of hardy herbaceous flowering plants in public gardens, and deprecated the extensive use of Pelargoniums and other tender subjects. Unfortunately, formal bedding cannot be dispensed with entirely in public pleasure grounds, as many retain a special liking for flat, uninteresting beds, and for carpet bedding. Beds of brilliantly-flowered Pelargoniums give bright patches of colour, but they are otherwise not artistic. In some positions they appear in keeping with their surroundings, such as near buildings, or on terrace gardens, where everything else is purely formal. But even in these cases, more pleasing effects may be obtained by introducing a few taller plants as relief. In sheltered positions, the following combinations make effective beds: (1) a groundwork of a pale blue *Viola*, planted with *Centaurea candidissima*, *Lobelia cardinalis*, and orange-flowered Iceland Poppies; (2) pale blue *Violas* as a ground, intermixed with *Fuchsia "Rose of Castile"* or another suitable variety of the same colour, and Pelargonium *Verona*. In any combination of this character care should be taken that the flowers harmonise in colour. It is not advisable to employ hard contrasts in colour; but this difficulty can be overcome to a large extent by adding other plants of a softer shade of one of the prominent colours. In cold, bleak positions, such hardy plants as *Golden Privet*, *Prunus pissardii*, and *Acacia loxantha* should be extensively employed. One often sees what otherwise would be a beautiful lawn or stretch of grass cut up and disfigured by scrappy flower-beds. A well kept lawn, with trees and shrubs here and there, and a few irregular flower-beds arranged in recesses near the shrubberies, planted with bulbs, Delphiniums, Phlox, *Soldado*, *Helenium*, *Michaelmas Asters*, and similar plants, each in their season, and giving a touch of colour to the whole, makes a picture that is pleasing and restful to the eye at all seasons.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but they cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JANUARY 21—
British Gard. Assoc. Meet. at Birmingham. Soc. Française d'Hort. de Londres Ann. Dinner.

WEDNESDAY, JANUARY 25—
Irish Gard. Assoc. and Benev. Soc. meet.

FRIDAY, JANUARY 27—
Lee, Blackheath and Lewisham Hort. Soc. meet. (Lecture on "Chrysanthemums," by Mr. R. C. Pullen.)

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—39° F.

LOCAL TEMPERATURES.—
LONDON.—Wednesday, January 18 (6 p.m.): Max. 43; Min. 38°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, January 19 (10 a.m.): Bar. 30.6 Temp. 42; Weather—Dull.

PROVINCES.—Wednesday, January 18: Max. 48 Ireland S.W.; Min. 40° Yorkshire.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Herbaceous and other Plants, Lilies, Hardy Bulbs, &c., at 12; Roses, Fruit Trees, &c., at 130; at 67 & 65, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Lilies and other Hardy Bulbs, Perennials and other Plants, at 12; 6,000 Roses at 130; Palms and Plants at 5; at 67 and 65, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Imported and Established Orchids, at 67 & 65, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The prevalent theory as to the nature of soil fertility holds that every plant requires, in addition to carbon, certain elements which can obtain only from the soil, and hence that crops depend upon the presence in the soil, and the absorption therefrom by the plant, of minimal quantities of each of these elements. If one of the necessary elements is present in the soil in insufficient quantity, the crop fails, no matter to what extent the other mineral elements are available to the plant. Similarly, the beneficial effect of fertilisers is attributed to the fact that they restore to the soil some element—nitrogen, phosphorus, &c., in which it has become deficient.

In practice, only four of the 18 or 20 elements generally present (in combined form) in plants are added in this way to the soil. Of those which the cultivator neglects to add, some—carbon, oxygen and hydrogen—are supplied to the plant from the air or in the form of water.

Other of these elements exist in the soil in such quantities as to provide the plant with practically inexhaustible supplies, and others again—for example, manganese, zinc, barium, and copper—occur in such small quantities in the plant that they are generally regarded as unessential.

According to these theories, the soil is to

be regarded as a reservoir from which the plant receives its mineral food materials, and fertilisers are looked upon as providing supplementary supplies of these food materials; in other words, the fertiliser acts on the plant and not on the soil.

As we have pointed out on more than one occasion, this theory of soil fertility has been extended of recent years, and the soil is no longer regarded merely as an inert reservoir, but as the seat of chemical and vital actions which have a considerable influence on its fertility.

The older view regarded the root of a plant as an absorbent organ only. What the soil presented to it in a soluble form it absorbed, but the root itself was without action on the soil. The newer view, on the contrary, considers the root not only as an absorbent organ, but as one which is capable of setting up chemical changes in the soil, which changes may result in modification of the soil fertility.

Much has been written from time to time on this subject of root-secretion, some experimenters maintaining that carbon-dioxide is the only material discharged by the root-hairs; others, that roots habitually give off other and more active chemical substances.

A careful investigation on this subject by Messrs. Schreiner and Sullivan has just been published by the Soil Bureau of the U.S. Department of Agriculture. The object of the research was to determine the oxidative powers possessed by the roots of plants. The practical importance of the investigation is evident, for if roots possess marked powers of setting up chemical change in the medium in which they grow, they must clearly produce considerable effects on the composition of that medium, and hence may themselves play a part in modifying the fertility of the soil.

The method used by Messrs. Schreiner and Sullivan was ingenious, and consisted in growing plants (Wheat) in nutrient solutions, to which certain innocuous organic substances were added, these substances being of such a nature as to give rise when oxidised to dyes of definite and recognisable colours.

The best reagent for thus testing the oxidative powers of roots was found to be aloin. When dissolved in water, this substance is yellow, but when oxidised it becomes of a claret-red colour. This change from yellow to claret-red was found to occur when aloin was added to the solution containing living roots. Further, by measuring the depth of the colour developed, it is possible to obtain an accurate estimate of the amount of oxidative change set up by the roots.

Perhaps the most important conclusion arrived at by these investigations is that oxidation in soils is a purely chemical process, and is not due to the agency of enzymes. It is found, moreover, that the rate of oxidation in soils is increased by the addition of salts of manganese, iron, calcium and magnesium, and particularly by the first-named compounds. Hence it may be that the known stimulative action of manganese salts on plant-growth is to be attributed, in part at least, to their oxidative action on the soil rather than to any action in the plant itself. Such an interpretation of the effects of manganese in promoting soil fertility is certainly worthy of consideration, and should be made the subject of further experiment.

OUR SUPPLEMENTARY ILLUSTRATION.—
Diospyros Kaki, the Persimmon, or Japanese Date Plum, is a tree of Apple-like habit, and, in Japan, it occupies a similar position among cultivated fruits to that filled by the Apple in this country. There appear to be as many varieties of the Kaki as of the Apple, something like 800 of the former being cultivated in Japan. They are divided into two classes, namely, dessert and culinary. They vary in hardness, some of the varieties bearing a larger degree of cold than others. The fruits ripen slowly, growing to full size and colouring about three months before they are actually ripe. In Japan, the ripening process is hastened artificially, a sure method being that of spraying the fruits with alcohol, and placing them in air-tight boxes or casks—treatment which, in a few days, turns a fruit as hard as wood into one with the mellowness of a ripe Peach. The flavour of the fruit varies considerably; in some it is astringent and disagreeable, and these are, therefore, only fit for food after they have been cooked. But many of them are sweet and juicy, too sweet, indeed, for some palates. They are sometimes offered for sale by leading fruiterers in this country, and in France there is, we believe, a fair demand for them. The tree though quite hardy in the south of England does not succeed out-of-doors at Kew; but, under glass, with treatment essentially the same as is given to Plums and Peaches, it has succeeded for the last 10 years. The example shown in the illustration has been established in a border at the cool end of the succulent house at Kew, where it fruits annually, the crop last year being close upon 100 fruits, each of which weighed about half a pound. The tree is only about 8 feet high, and the fruits, which have been in full colour since October, are still hanging. Their colour is bright orange-scarlet, so that, in addition to their value as food, they are distinctly decorative. Illustrations of the fruits and flowers of Diospyros Kaki were given in our issue for July 13, 1907, figs. 8, 9.

BRITISH GARDENERS' ASSOCIATION.—The secretary of this Association, Mr. J. WEATHERS, states that, during the past year, the Association has made greater progress than usual. Three hundred and fifty members have been elected, bringing the total up to 1,964 at the beginning of December. It is anticipated that early in the present year over 2,000 gardeners will have joined the Association since its establishment. The monthly *Journal* has been increased in size, and the Executive Council has adopted a scheme for a professional gardeners' examination. The first examination will be held on Wednesday, April 26, at 7 p.m.

—On Saturday, January 21, a public meeting of gardeners in the Birmingham district will be held at the Cobden Café, Corporation Street, Birmingham, at 7.30 p.m. Mr. JAMES UDALE will preside, and addresses will be given by the Chairman and Secretary of the British Gardeners' Association and other well-known gardeners. A cheap train will run at 2.55 p.m. from Burton-on-Trent to Birmingham.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held at the Institution on Monday, the 23rd inst., at 8 p.m., when a paper will be read by Mr. W. R. BALDWIN-WISEMAN on "The Conservation of our National Water Resources."

NATIONAL HARDY PLANT SOCIETY.—We are informed that at a meeting of the Council, held at Birmingham on the 12th inst., it was arranged that the Society should undertake to grant First-class Certificates and Certificates of Merit to new hardy plants of sufficient merit that may be exhibited at several of the leading shows, or that may be submitted to the Council during 1911.

VIEW IN THE SUCCULENT HOUSE AT KEW, SHOWING DIOSPYROS KAKI IN FRUIT.

GARDENERS' ROYAL BENEVOLENT INSTITUTION (WORCESTER AUXILIARY).—The 15th annual meeting was held on the 14th inst. at the Hop Market Hotel, Worcester. The meeting was preceded by a dinner, at which a party of about 40 was presided over by the Mayor of Worcester, supported by Councillors A. USHER and A. A. PREECE. The report and balance-sheet showed that the receipts of the Auxiliary for the past year had been £103, of which sum £94 had been sent to the parent institution, £5 had been spent on printing, &c., and the balance of £4 carried forward. The chairman congratulated the committee and all concerned on the splendid work the Auxiliary was doing in the county. On the proposal of Mr. CROOKS, the report and balance-sheet were adopted. The president, Earl BEAUCHAMP, was re-elected, and the best thanks of the members were accorded to him for his kindness in allowing Madresfield Gardens to be again thrown open for public inspection on Whit Monday last, the funds profiting thereby to the extent of £17 9s. 2d. The vice-presidents were re-elected, and the name of Councillor A. USHER added. The old committee was re-elected, also the hon. treasurer, Mr. JOHN WHITE, and the hon. secretary, Mr. PERCY WHITE. At the conclusion of the business, the party was entertained to a musical programme. Mr. W. CRUMP, Madresfield Court Gardens, gave the toast of "The Institution." He explained to his hearers the benefits gardeners may obtain by subscribing to the Institution. The toast was received with applause, and Mr. PERCY WHITE (hon. sec.) and Mr. J. W. SEDGELEY (a pensioner) responded. During the evening six new annual subscribers and two life members were enrolled.

R.H.S. GARDENS CLUB.—The third number of *The Journal* published by the club of past and present students and employes of the Royal Horticultural Society is more ambitious than either of the two previous issues. There are several illustrations printed on art paper; the frontispiece shows the great vinery in the old Chiswick gardens, and there are also views of the Old Council Room and Library, the Palm House and the long vinery, which we believe was originally built for a Peach house. Mr. JOHN FRASER, in a note on the Old Clusack and the New, states that the Ivy-covered council room still stands, being almost the sole relic of the old gardens, the remainder of the place being laid out in streets for buildings. Mr. JOHN BARRY gives some very interesting reminiscences of Chiswick, dating from 1866. He speaks of PAXTON, FORTUNE, ROBERT THOMPSON, A. F. BARRON, BURBIDGE, HEAD, BAUSE, JOSEPH LEE, SUMMERS, and others who have been connected with those celebrated gardens. Mr. HERMAN SIGONER gives some suggestions for a horticultural museum. Mr. HARRY J. VEITCH writes on the International Horticultural Exhibition, 1912. Referring to the similar exhibition of 1866, he says:—"In 1866 the largest class for Orchids was 50 plants, and one cannot help smiling as one recollects some of the kinds exhibited to complete the 50, such as *Aspasia lunata*, *Epidendrum odoratum*, *Oncidium flexuosum*, and others, while to-day such a group would be nowhere in competition. We who are now accustomed to see *Dendrobium Wardianum* exhibited in such masses and so finely bloomed, find it difficult to realise that special mention is made of a plant being exhibited in 1866 carrying two flowers, also that *Odontoglossum crispum* (Alexandra) was then almost an unknown plant, having been bloomed for the first time in this country in 1864, and that such fine Cattleyas as *C. Mendelii* and *C. Dowiana* were not then in cultivation. The Orchid which then took the first prize as the best novelty was *Aerides japoni-*

num!" A flora of Wisley is commenced by Mr. F. J. CHITTENDEN, assisted by Messrs. A. TIMMONDS and W. D. CARTWRIGHT. There are also several interesting letters from students abroad, and a cultural article on tuberous-rooted winter-flowering Begonias.

KEW GARDENERS' SOCIAL EVENING.—The 14th annual social gathering of the Kew Garden staff was held on Friday last, at the Boat House, Kew. About 120 were present, including several ladies and the Assistant Director, Mr. A. W. HILL, M.A. Music, dancing, and a whist drive constituted the chief items of the programme. Mr. SMITH officiated as master of the ceremonies, and Messrs. BEALE and GREEN as stewards.

BOARD OF AGRICULTURE AND SMALL HOLDINGS.—According to *The Times* the Soke of Peterborough County Council having refused to put the compulsory clauses of the Allotment and Small Holdings Act into force for the acquisition of land in the parish of Newborough, the Board of Agriculture has notified that, unless the local authority prepares a scheme within 30 days, its Commissioner, Mr. CHENEY, will draft one which the Board will carry into effect at the expense of the council.

THE INTERNATIONAL EXHIBITION.—Queen ALEXANDRA has consented to become a patroness of the International Horticultural Exhibition to be held at Chelsea in May next year.

DIRECTORIES, ALMANACS, DIARIES, AND OTHER ANNUALS.—The new editions of the various works of reference make their appearance as usual with the New Year. Amongst the more useful of these publications to the gardener, nurseryman, and florist are the two horticultural directories, *The Garden Annual, Almanac, and Address Book*, and *The Horticultural Directory and Year Book*, the price of each volume is 1s. Each gives, in alphabetical order, a list of the most important gardens in Great Britain, with the names of the owners and post towns. The addresses are also given again under the respective counties, whilst the names of the gardeners are arranged alphabetically in a separate list. The principal nursery and seed firms, both at home and abroad, are included; also the names and addresses of the secretaries of the more important horticultural societies and garden institutions. Both works contain a list of new plants, as well as other interesting gardening information. *The Gardening Year Book and Garden Oracle*, edited by GEO. GORDON, V.M.H., price 1s., makes its appearance for the 53rd time. It contains a calendar with daily reminders of garden operations, and useful cultural hints are given in chapters dealing with each month's work. Descriptions of novelties will be found valuable, and there are also articles on bulbous and tuberous-rooted plants, Ferns, Roses, flowering shrubs, hardy perennial flowers, insect pests, and other subjects. Information is given concerning the principal public parks and gardens in Great Britain, also the addresses of the secretaries of the chief horticultural societies. The work contains two coloured plates besides other illustrations. *My Garden Diary for 1911*, issued by Messrs. SUTTON & SONS, Reading, is a dainty little calendar, printed on art paper. The reminders for the various months will be of value to the amateur, who is also guided in a selection of flowers that may be easily raised from seeds. *Webster's Foresters' Diary and Pocket Book* (price 2s. 6d. net) contains much information for foresters and gardeners. Under each month is given seasonable work in forestry, followed by rules for planting, thinning, and pruning, also hints on the cultivation of Osiers. The tables given will be useful in other branches of estate

management than forestry. But the volume will also serve as a reminder of events, for it forms a most convenient pocket diary, provided with ample space on each date for making entries. *The Live Stock Journal Almanac*, *Vinton's Agricultural Almanac and Diary*, and *Irish Farming World Directory and Annual* are intended more for the farmer than the gardener; nevertheless, they all contain hints useful in any branch of estate management. Amongst works of a more general character, *Who's Who* (A. & C. BLACK, price 10s.) is a valuable book of reference. The volume contains short biographies of about 25,000 celebrities. Companion volumes, *Englishwoman's Year Book and Directory* (price 2s. 6d. net) and *The Writers' and Artists' Year Book* (price 1s. net), are issued by the same firm. *Willing's Press Guide*, price 1s., forms a comprehensive index to the Press of the United Kingdom. There are also lists of the principal colonial and foreign publications, as well as other information on journalistic matters. *The British Journal Photographic Almanac* (price 1s., cloth 1s. 6d.) is a bulky volume of 1,346 pages, attractively bound in green cloth. Photography is an art that advances by leaps and bounds each year, and those who wish to study the progress made during 1910 will find the book teeming with information. *Pears' Cyclopaedia*, price 1s., furnishes a vast amount of information on almost every subject, being a dictionary, gazetteer, and cyclopaedia rolled into one.

INTERNATIONAL INSTITUTE OF AGRICULTURE.—The Board of Agriculture and Fisheries is informed that the International Institute of Agriculture has arranged for the sale of the publications of the Institute to the public at the following subscription rates as from January 1, 1911: *Monthly Bulletin of Economic and Social Intelligence*, 18 francs; *Monthly Bulletin of Agricultural Intelligence and Diseases of Plants*, 18 francs; *Monthly Bulletin of Agricultural Statistics*, 6 francs; combined subscription for all three publications, 36 francs. All communications should be addressed to the General Secretary, International Institute of Agriculture, Rome.

LIVER OF SULPHUR AS A FUNGICIDE.—The fungicide known commercially as Liver of Sulphur, and made by heating sodium or potassium carbonate with flowers of sulphur, is now used in large quantities to combat the ravages of the American Gooseberry-mildew and other fungous pests. But little is known of its composition or of the reason for its fungicidal properties, and therefore the enquiry made by Mr. F. W. FOREMAN, of the School of Agriculture, Cambridge, at the instance of the Board of Agriculture, is to be welcomed. The conclusion arrived at is that the fungicidal action of Liver of Sulphur is mainly due to the free caustic alkali present or to that produced by the decomposition of the polysulphides which are among the constituents of the mixture. Mr. FOREMAN doubts whether the sulphur present has any marked fungicidal action. He finds that Liver of Sulphur made with soda is more effective, as well as cheaper, than that made with potash, a point of considerable practical utility to the gardener. He further suggests that the solutions of caustic soda, much weaker than those of liver of sulphur usually employed, might be quite as effective as the latter, and far less costly.

PUBLICATIONS RECEIVED—Board of Agriculture and Fisheries. Leaflet No. 179: The Making of Soft and Cream Cheeses and Clotted Cream (London: Board of Agriculture and Fisheries, 4, Whitehall Place).—**Department of Agriculture, Trinidad.** Bulletin, Vol. IX., No. 66. (Trinidad: Government Printing Office, Port of Spain.)

SCOTLAND.

PROPOSED GARDEN CITY IN AYRSHIRE.

PLANS have been prepared on behalf of the Duke of Portland for a garden city at Barassie, near Troon. The site chosen runs parallel with the railway on the shore side, and will extend over an area of 60 acres. Practically all the land from Barassie to the southern boundary of the Western Golf Club will be included in the scheme.

THE PROPOSED AMALGAMATION.

CONSIDERABLE regret is felt in Scottish horticultural circles that the joint committee appointed to consider the question finds itself unable to recommend the amalgamation of the Royal Caledonian Horticultural Society and the Scottish Horticultural Association, on account of certain legal difficulties. The general principle that such amalgamation is highly desirable is accepted, but the limitations of the existing charter of the Royal Caledonian Society constitute an obstacle. Apparently this charter contains no provision for dissolving the society, or this might have been effected and a new body constituted, including the members of both. The adoption of a new charter means, it appears, long and troublesome negotiations, and the cost would be very considerable. There are minor difficulties in the way, but the spirit of mutual accommodation and assistance present in both bodies could overcome these.

It appears to be a great waste of energy and organisation to maintain two central Scottish horticultural societies, with their headquarters in Edinburgh, and with practically the same men at their heads. Neither society is so strong or so influential as it ought to be, and things are not likely to improve until unity is secured. If nothing can be done without obtaining a new charter, the best plan to adopt is to apply for the charter at once. The expense will be amply repaid afterwards.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

THE annual abstract of the accounts of the Scottish Horticultural Association, issued to the members with the notices for the annual meeting, shows a slightly improved financial position, as against a decline at the end of the previous year. This improvement appears to be partly due to the council having arranged a sale of flowers and provided various attractions on the day after the Chrysanthemum show closed. The proceeds of these amounted to £29 0s. 10d., which, with other gains at the Chrysanthemum show, yielded a balance of £43 16s. 11d. to be carried to the general funds of the association. The loss on the show of 1909 was no less than £141 1s. 1d., so that the improved position is most gratifying to all concerned with the show. The general accounts reflect this improvement, as, while the loss in funds in 1909 was £165 7s. 11d., the gain in 1910 was £43 11s. 8d.

ROYAL SCOTTISH ARBORICULTURAL SOCIETY
(ABERDEEN BRANCH).

THE annual meeting of the Aberdeen branch of the Royal Scottish Arboricultural Society was held in Aberdeen on January 14. There was a large attendance, presided over by Mr. Sidney J. Gammell, the president.

A highly satisfactory report was submitted by the secretary, Mr. G. D. Massie, this showing progress in membership and also a slight improvement in the financial position, which is a good one. Mr. Sidney J. Gammell, of Drumtochty, was re-elected president, and Mr. Massie secretary.

A valuable paper was read by Mr. D. Munro, Banchory, on the subject of "The Home Timber Outlook and the Urgent Need for Afforestation." Mr. Munro pointed out the imminent danger of the exhaustion of the supply of foreign and Colonial timber, with the exception of certain kinds, and the necessity of arranging for afforestation and re-afforestation in Scotland. From his own experience, Mr. Munro stated that in Scot-

land they were almost at the end of the timber supply, and that at present many of the mills could hardly be kept in operation, from an insufficient supply. He advocated the planting of Larch, Scots Fir, Spruce, and Douglas Fir. He also laid great stress on the necessity of waging war on vermin, and showed conclusively the amount of injury to woods caused by the squirrel. In valuing two woods recently, he estimated that the damage done by squirrels might amount to as much as £15 per acre.

CYANANTHUS.

THE genus *Cyananthus* belongs to the Natural Order Campanulaceæ, and is closely allied to *Codonopsis*. Its members are confined to the Himalayas and mountains of Western China, and in all number about 12 species, seven being found in the first-named range of hills, while five are natives of China. Five species have been introduced into cultivation, three of them, *C. lobatus*, *C. microphyllus*, and *C. incanus*, being perennials; whilst the other two, *C. Hookeri* and *C. inflatus*, are annuals. From a

FIG. 23.—CYANANTHUS MICROPHYLLUS:
FLOWERS BLUE.

garden point of view, the two latter species are hardly worth growing, but the three perennials are charming little plants, with beautiful flowers. They are of easy cultivation and thrive well in cool, shady situations in loamy soil mixed with leaf mould and sand. Thorough drainage is essential, and some good-sized pebbles should also be mixed with the soil, as the long, fleshy roots delight to ramble amongst them. Seeds are seldom produced in this country, but the plants are easily increased by means of cuttings taken early in autumn.

C. LOBATUS.—This is the best known species in gardens. It is common in the Himalayas from Gurwal to Sikkim, at an elevation of 11,000 to 14,000 feet, where it forms large tufts of trailing stems, with each branch bearing terminal flowers. A flourishing specimen is a very beautiful plant, and it flowers freely during August and September. Although this species has been in cultivation since 1844, it is not a common plant, and is not so much grown as it deserves to be. It is figured in the *Botanical Magazine*, t. 6435.

C. INCANUS.—A figure of this scarce species, growing in the Botanic Gardens at Glasnevin, is given in the *Gardeners' Chronicle*, 1909, vol. xvi., p. 422. Its natural habitat is Sikkim, where it occurs at very high elevations—12,000 to 16,000 feet. It is a smaller growing plant than *C. lobatus*, and it produces azure-blue flowers in August and September. The stems are thin and wiry, many being produced from the central root-stock. A variety of this species, with yellow flowers, *C. incanus* var. *leocalyx*, was introduced into cultivation in 1905 by Bees Ltd., having been sent home by Forrest, who collected it in Yunnan. In all respects save its yellow flowers it is like the type.

C. MICROPHYLLUS (see fig. 23).—Seeds of this species were received in 1900 from Saharnipur Botanic Garden, under the name of *C. linifolius*. Plants flowered in August, 1904. The somewhat straggling stems are thin and wiry, with small, sessile leaves, which are glabrous above and scabrid pilose beneath. The flowers, which are light blue, are three-quarters of an inch long, and have a ring of white hairs at the throat. The species comes from Kumaon, where it is found on the margins of rivers at an elevation of 11,000 feet. Two other Himalayan species not in cultivation, *C. integer* and *C. pedunculatus*, are very closely allied to this species.

The two annual species, *C. Hookeri* and *C. inflatus*, have been in cultivation at different times, a variety of the former having been sent from Western China by Wilson, Messrs. Veitch's collector, in 1905. *C. inflatus* has also been received at different times from the Himalayas. W. L.

NOVELTIES OF 1910.

(Concluded from p. 28.)

MISCELLANEOUS FLOWERS.

A STERLING novelty, which is likely to be largely grown, is the new Marguerite "Mrs. F. Sander," exhibited at the Temple Show by Messrs. SANDER & SONS. The great superiority of this variety over Coronation and other double varieties is likely to make this plant one of the most remarkable novelties of the year.

Messrs. R. W. WALLACE & Co., Colchester, flowered some charming new Irises of the Michael Foster strain, and they secured Awards for Isoline and Italia on June 7.

For tuberous Begonias, there is a falling off in certificated novelties, although Messrs. BLACKMORE & LANGDON appeared to show these flowers better than ever. They obtained awards only for Rose Queen and Mrs. W. L. Ainslie.

Robinia Kelseyi, a hardy-flowering tree or shrub, was certificated to Messrs. R. VEITCH & SON, Exeter. Mr. AMOS PERRY showed several beautiful Delphiniums. Lamartine and Belladonna semi-plena being very handsome flowers. *Osmunda palustris crispata-congesta* is a densely-crested Fern, shown by Messrs. H. B. MAY & SONS; and Gladioli and other favourite garden plants have received some recruits.

Turning to the class which appeals to all gardeners, large and small, namely, plants which can be raised annually from seeds, Messrs. DOBBIE & Co. have shown that they continually improve their strains of Violas and other showy flowers. They obtained awards for their fine strains of *Calendula*, *Cosmos* "Rose Queen," and *Gypsophila carminea*. Messrs. KELWAY & SON, Langport, have exhibited Gaillardias, Delphiniums, Pyrethrums, and Gladioli. Pyrethrum "Snow Queen," a single white flower, obtained an Award of Merit on June 7. Various other useful plants have been certificated, amongst which may be mentioned *Rhus typhina laciniata* (R. C. NORCUTT, Woodbridge); two pretty pink Astilbes from Mr. ABRENS, Ronsdorf; *Rhododendron Alice* and *R. Princess Juliana* (J. WATERER & SONS, Bagshot);

Lonicer a pileata, a cream-white Chinese shrub (Geo. Paul & Sons); *Polyanthus* Ladham's Brilliant (B. Ladham, Ltd., Southampton); *Mertensia echioides elongata* (Bakers, Wolverhampton); *Gladiolus* King Edward VII. (Frank Liley, Guernsey), *Heliotrope* "Favourite" (King's Acre Nurseries, Hereford), and *Saxifraga scardica obtusa* (a pretty, white-tufted species) and the large-flowered *Shortia uniflora grandiflora* from Sir Everard Hambro.

At the Royal Horticultural Society's meeting, held on August 16, Mr. Pfitzer, Stuttgart, showed a fine strain of *Gladiolus*, and was given Awards of Merit for three varieties.

The following new and noteworthy plants and fruits have been illustrated in the *Gardeners' Chronicle* during 1910:—

- Agave Franzosinii*, June 18, p. 408.
- Agave Elmoeitiana*, March 26, p. 501.
- Androsace Henryi*, May 28, p. 315.
- Androsace spinulifera*, Jan. 8, p. 27.
- Anoptaxis glandulosus*, Sept. 10, p. 194.
- Apple Ard Cain* Russet, Nov. 26, p. 389.
- Apple Houslow Wonder*, Oct. 22, p. 365.
- Alectorurus yedoensis*, Nov. 12, p. 352.
- Aristolochia gigas* Sturtevant in Ceylon, April 16, p. 11.
- Aristolochia Warley*, April 30, p. 274.
- Astilbe simplicifolia*, Oct. 22, p. 294.
- Aster Falconeri*, June 18, p. 398.
- Bidens dahliaefolia*, Sept. 24, p. 226.
- Calyptegia dahurica*, Dec. 31, p. 483.
- Campanula pusilla alba*, Aug. 6, p. 96.
- Campanula Portenschlagiana major*, July 23, p. 58.
- Campanula barbata*, Nov. 26, p. 388.
- Cassiope fastigiata*, June 11, p. 379.
- Carnation Empire Day*, June 18, p. 413.
- Carnation Lady Hermoine*, June 11, p. 388.
- Carnation Mrs. E. Martin Smith*, June 25, p. 422.
- Carnation Forester*, Aug. 13, p. 128.
- Carnation Enchantress*, March 12, p. 163.
- Carnation Mrs. Tatton Sykes*, March 5, p. 146.
- Carlina acanthifolia*, Jan. 29, p. 68.
- Chionanthus retusa*, May 21, pp. 328-329.
- Chionosilla The Queen*, Dec. 17, p. 455.
- Colecium veratrifolium*, Oct. 1, p. 242.
- Clematis nutans*, Oct. 29, p. 310.
- Cineraria Sutton's hybrid*, May 28, p. 356.
- Corypha umbraeflora*, Supp. June 25.
- Cola acuminata*, Jan. 8, p. 30.
- Cnicifuga racemosa*, Sept. 17, p. 218.
- Crinum Moorei*, July 23, p. 59.

- Tricuspidaria dependens*, Jan. 29, p. 75.
- Utricularia prolensis*, Dec. 17, p. 447.
- Viburnum Henryi*, Supp. Oct. 8.
- Welwitschia mirabilis* male and female flowers, Supp. Jan. 25, p. 50.
- Zephyranthes* in Ceylon, Sept. 10, p. 156.

WEATHER AT ROTHAMSTED IN 1910.

THE meteorological records of the Rothamsted Experimental Agricultural Station, Hertfordshire, for 1910, show that the year was characterized by a great excess of rain, even more than that of the year 1909; in fact, the total amount has been equalled or exceeded only about ten times during the past 58 years. This was largely owing to the enormous quantity which fell in December, viz., 5.36 inches. Only once in December since the year 1853 has the rainfall at Rothamsted exceeded this amount, namely, in 1876, when 6 inches were recorded. The number of rainy days was 196, being 24 in excess of the average.

The mean temperature of the year was slightly in excess of the average. The most unseasonably warm months were February, October, and December. The last month of the year was 5.4° warmer than November, and only 3° colder than April.

The bright sunshine was 221 hours deficient for the year, there being but four months which showed an excess compared with the average, and eight months of deficiency. March gave the greatest excess of sunshine, namely, 42 hours, and July recorded the largest deficiency, namely, 98 hours. The four months of June to September, which make up the usual Hay and Corn harvests of this country, gave a total deficiency of 203 hours of bright sunshine.

The following table shows the rainfall of each month for the past year at Rothamsted, with the average amount of rain for each month of the previous 57 years, 1853-1909, and the difference of 1910 above or below the average record:—

RAINFALL AT ROTHAMSTED, HERTS., 1910.

Months.	Rainfall 1910.	Average Rainfall of 57 years.	1910. Above or below the average.
	Inches.	Inches.	Inches.
January	2.18	2.31	-0.15
February	3.78	1.77	+2.01
March	1.23	1.80	-0.56
April	1.58	1.88	-0.30
May	2.16	2.17	-0.01
June	2.81	2.43	+0.38
July	2.00	2.53	-0.53
August	3.38	2.64	+0.74
September	0.89	2.41	-1.52
October	2.83	3.19	-0.36
November	3.93	2.54	+1.39
December	5.36	2.33	+3.03
Yearly Total	32.13	28.11	+4.02

(1) The sign in the last column (+) signifies above the average, and the sign (-) below the average.

The rain-gauge, which is one-thousandth part of an acre in dimension, stands 2 feet above the surface of the ground, and is 420 feet above sea level.

The above data show a total rainfall of 32½ inches, against an average for the previous 57 years of 28½ inches, being slightly over 4 inches in excess.

Estimating the rainfall in tons per acre, we find that, during the whole year, 3,245 tons of water have fallen on each acre of land, which is 406½ tons of water in excess of the average in this district. The two months of November and December alone gave an excess of rainfall amounting to 445½ tons of water per acre.

The next table shows the mean temperature in the shade for each month of the year 1910, with the excess or deficiency at the Rothamsted station during the past 32 years, 1878-1909; also the number of hours of bright sunshine taken by means of a Campbell Stokes recorder for each month, and the number of hours above or below the average record:—

MEAN TEMPERATURE AND BRIGHT SUNSHINE AT ROTHAMSTED, FOR THE YEAR 1910.

Months.	Mean Temperature.		Sunshine.	
	1910.	Above or below average.	1910.	Above or below Average.
	Degrees	Degrees.	Hours.	Hours.
January	38.4	- 1.7	74	- 20
February	40.7	+ 2.5	80	+ 8
March	41.8	+ 0.9	159	+ 42
April	45.9	+ 0.3	117	- 54
May	52.6	- 1.2	199	- 1
June	58.7	- 1.5	186	- 12
July	57.5	- 3.3	123	- 98
August	59.5	- 0.1	153	- 52
September	54.5	- 1.3	118	- 41
October	51.8	+ 0.5	63	- 42
November	37.5	+ 5.1	86	- 26
December	42.9	+ 5.1	29	- 14
For the year	48.5	+ 0.6	1,387	- 218

The mean temperature, that is, the mean of the maximum and minimum temperatures of each day throughout the year, was 48.5°, which is 0.6° in excess of the previous 32 years. There were eight months of excess and four months of deficiency, the coldest month of the year being November, which recorded but 37.5°, or 5.1° below normal.

The total of bright sunshine for the year was 1,387 hours, against an average of 1,608 hours, showing a deficiency of 221 hours.

The last two months of the year having given an excess of 4.41 inches of rain, shows us that our underground water supply is 99,639 gallons of water in excess of the normal quantity on each acre of land in this district. J. J. Willis, Hatfield.

HOME CORRESPONDENCE.

The Editors do not hold themselves responsible for the opinions expressed by correspondents.

APPLES: BRITISH VERSUS FOREIGN.—A *Southern Fruit Grower* (January 7, p. 4) states a deplorable fact when he draws attention to the preference our shoppers give to foreign Apples over British grown fruits. It has been insisted upon over and over again that British Apples, when of good kinds, well grown, and properly stored, are superior to the fruit sent us from overseas. Yet, in spite of this, a *Southern Fruit Grower* tells us that, in this season of scarcity, English Apples have not paid for keeping. The prices which late Apples realised are ridiculous when compared with the 4d. and 5d. per pound at which the American Apple is readily retailed in the shops. Why is this? It cannot be that our purchasers are so unpatronising as to buy foreign fruits simply because they are foreign. I am strongly of the opinion that shoppers rarely consider the origin of the article they intend to purchase. The only point considered is whether or not it happens to be the kind of thing they need. So one is regretfully forced to the conclusion that, in the majority of instances, the consumer prefers the foreign Apple. The reason for this preference is not far to seek. What the foreign Apple lacks in firmness and rich juiciness

it makes up in showiness and in being more easily masticated. Many people cannot digest the firm-fleshed dessert Apples, and are unwillingly obliged to use the softer foreign fruit. The producer must be prepared to supply what the purchaser wants. It is not of the slightest use for him to say, "Here are Apples, grown in our own country, and possessing far superior qualities to the foreign fruit; these you must buy, they are better for you." This is not business. The duty of the producer is to supply what the consumer wants, no matter how misguided the buyer may seem to be. The grower will find it to his advantage to grow the softer-fleshed kinds of Apple. The argument against this procedure is that such kinds do not bear rough handling. The obvious answer to this is that they must not be handled roughly, and that, as they fetch a higher price, more care and time can be profitably bestowed upon them. I would not, for a moment, advocate the wholesale clearance of existing Apple trees to replace them with profitable kinds; but every tree which does not yield a good crop should be rooted out and replaced by saleable kinds. With regard to fruiting trees, their produce should be treated as the American does his. That is, gather the fruits just before they are ripe, and, after grading them, pack them closely in boxes, barrels, and such-like receptacles, and store them in a dark place. By this treatment the Apples will be soft-fleshed, and have that delicate, Peach-like colour which is so attractive and remunerative. This advice to gather Apples when they are green and unripe may seem to many people a suicidal procedure, but there is nothing of the nature of an experiment about it. I have successfully treated Apples in the manner described, and they had all the appearance and flavour of the highest grade of imported fruits. *A. C. BULLOCK.*

STREET TREES AND GAS. The life of a street tree is never a very happy one. Of all class of artificially-grown plants it undoubtedly has the most trying time. I have pointed out in the *Gardener's Chronicle* (February 12, 1910, p. 101) the conditions with which it has to contend underground in the way of pipes and cables, and the trouble above ground with dust and fumes. But these are not the worst enemies; at least, they are not what one would call fatal in their injuries, although, of course, they shorten life. The gas main is in itself a great trial to the roots, but when there is the smallest escape of gas it is far worse. Many of the mysterious and sudden deaths of healthy town trees may be attributed to gas leaks. Until one looks at the figures issued by gas companies, one does not realise the enormous amount of leakage there is. I have before me the figures of the Gas Light Commissioners of Massachusetts, which show that during last year the total quantity of gas unaccounted for by this company was the enormous amount of 622,304,044 cubic feet. In other words, there was a loss of about 10 per cent. on the total production. It is not every gas company that has such a record of lost gas as this, but, all the same, it may not be the worst case. The causes of leakage are various. Probably one of the chief causes is the sinking of ground and the consequent straining of the joints. In the United States there are special laws dealing with this matter, and the company, having to make good any loss caused by gas, is very careful to have the very best fittings and to see that all the joints are securely gulked. Investigating this injury from gas, I have found that a very small leak indeed, not sufficient to be noted by the company, is sufficient to kill the strongest tree. Even a few feet of gas leak is fatal, especially in heavy soils and where the surroundings are paved, for, in a very short time the ground becomes charged with gas and the roots are poisoned. When all the roots are in the poisoned area it is easy to see the effect on the whole tree, as the leaves turn yellow and fall prematurely, and the wood turns an unaccountably dark colour. When only one main root is affected by the gas, the result is peculiar, as for some time only the part of the tree supplied by that root suffers from injury, but the lower part of the tree feels its lack in great strips. I have before me photographs of Elms on the Garden City Estate at Leitchworth, where pieces of bark a yard square have fallen from the tree. The first intimation of this "local" poisoning

is the shedding of the bark from one side of the tree. The first year it may only be a square foot, leading from the soil level, but in the course of a year or two the bark comes off in huge strips, and the tree becomes unhealthy, and either succumbs to its natural enemy, the Elm-tree beetle (*Scolytus destructor*), which is always waiting for a favourable opportunity, or dies at once as a result of the poison. Where there is only part of the root system in the poison zone it is possible to save the tree by at once checking the cause of the damage, but where the whole of the soil has become charged with gas it is impossible to save the tree, as its leaves drop and nothing will make them come again. The great difficulty in this class of injury is the location of the seat of the trouble, especially in those districts where a main has been recently laid, as the escaping gas will travel along the loose earth, sometimes for a hundred yards, before it comes in contact with roots. It is obvious, therefore, that the town tree-planter has a difficult task to deal with this matter, and one can see only too often where he has failed in almost every town, as we are all familiar with the sudden death of street trees. What is the remedy? Or rather, what are the means of prevention?—For remedy there is none. Prevention lies in seeing that the engineers look properly after their work when mains are being laid. Too often the mains are laid by a contractor who has little or no interest in the gas company, and so long as the joints stand while the engineer tests the length it is sufficient. The gas companies know that minor leaks always occur in the course of time, and they fix the price for gas with this taken into account, but, apart from the waste of gas, this should not be, for it may mean that whole streets of beautiful trees may be killed, and this not only means the loss of the shade trees, but also the depreciation of property. I possess photographs of whole streets of trees dead from the effects of gas leaks. Too often the town forester is under the rule of the engineer, but here is a case where he should lose no opportunity for putting the engineer under his rule, and if the engineer will not see the whole of the pipes laid, it is the duty of the forester to see that he does. If he sees bad joints being made or the pipes laid over lightly-rammed soil, he should call the engineer's attention to it, and see that the matter is remedied. It may seem a small advice to give, but one should remember that the engineer, with his high salary, is like the forester a paid servant of the public, and if scamped work is pointed out to him, he will, while resenting the interference, see that it is remedied, and, that is all that is wanted. One very common cause of gas leaks is electrolysis, caused by the escape of electric current, but that subject is one which may be considered in connection with the effects of electrical discharges from damaged wires. *Pem.*

RAINFALL IN 1910.—I enclose the record of the year's rainfall taken in these gardens. The total fall amounted to 30.81 inches compared with 28.87 in 1909 and 24.26 in 1908. The heaviest downpour occurred on June 11, and amounted to 1.07 inch. December proved the wettest month with 4.45 inches, whilst February, June, and November all proved exceptionally wet. The hottest day was June 5, when the thermometer reached 87°. The greatest cold, 18° of frost, was registered on January 27. *Herbert Juniper, Dyrham Park Gardens, Bristol.*

—The records of the rainfall here during 1909 showed that August was the wettest month, with 4.14 inches, rain falling on 22 days, and that September was the driest month, with only .40 inch, rain falling on 11 days only. November and December were both very wet, with 3.42 and 3.23 inches of rain respectively. The heaviest rainfall in 24 hours occurred on October 11, and amounted to 1.23 inch. The total rainfall for the year was 28.16 inches. *C. Frankish, Waltham Hall Gardens, Lincolnshire.*

—Last year was the wettest season for more than 10 years at Bryanston, the total fall for the year amounting to 48.50 inches. The greatest rainfall for one month was 3.62 inches in December, rain falling on 23 days. The driest month was September, .23 inch being the total

record for that month, the heaviest fall for one day being 1.55 inch, which occurred on October 12. More than 1 inch of rain in 24 hours was recorded on seven occasions. *J. Jaques, The Gardens, Bryanston, Blandford, Dorsetshire.*

—Rain fell in these gardens on 195 days, the year's rainfall amounting to 41.08 inches. In December 6.72 inches fell, and in November 5.44 inches. September was the driest month, with a fall of .26 inch only. February, April, August, November, and December had each 20 rainy days or more. *J. S. Higgins, Rug Gardens, Corwen, N. Wales.*

INCURRED CHRYSANTHEMUMS.—The report of Mr. W. Higgs's lecture before the National Chrysanthemum Society on the cultivation of incurred Chrysanthemums has doubtless been read by growers for exhibition with special interest. It is the teaching of a master exhibitor who is also a master grower. But the chief value of the lecture seemed to me to lie in the paragraph on the dressing of flowers. What a free admission seemed to be made in that paragraph that, let the varieties be never so fine, the primary work of presenting them for competition was done by the dresser who evidently must be an expert manipulator. Mr. Higgs told his hearers that some flowers take an hour to be properly dressed. If this is so, the work of dressing 24 or 36 blooms must be very onerous, and after all this dressing may the flower be described as natural or artificial? How sadly does all this reflect on exhibition ethics. *D.*

LAW NOTE.

THE TAX ON MALE SERVANTS.

A CASE concerning the employment of a male servant without a licence was tried in the King's Bench Division on Monday last.

The respondent, says *The Times*, had employed one William Taylor as a jobbing gardener for four days a week, and had paid him 4s. 6d. per day, and 2s. a week extra for attending to his greenhouses. Taylor was at liberty to work for another employer in the same capacity on those days he was not employed by the respondent, and, if Taylor could not attend to the respondent's work himself on any day, he was to send a qualified substitute, as he had, in fact, done on several occasions. Taylor worked greenhouses of his own, and frequently supplied the respondent with plants from them.

For the respondent it was contended that Taylor was a jobbing gardener, under contract to work on certain days of the week or to send a substitute; and to supply plants in his capacity as a tradesman to the respondent, and that he was not in the position of a male servant within section 19 (3) of the Revenue Act, 1869.

The Justices came to the conclusion that the term "male servant" did not include a gardener employed under such circumstances, and dismissed the summons.

The Lord Chief Justice said they must recognise that, in a large number of instances, especially in the case of persons who had a garden which was not large enough to occupy the whole time of a gardener, it was a common practice for a nurseryman to do a gardener's work occasionally. The question, therefore, could not be solved by looking simply at the class of work that the man had to do.

If a taxable servant did work which made his master liable, the master would not escape the tax by reason of the servant doing some other work. But a master did not become liable in respect of a non-taxable servant simply because he did some work which would make a servant taxable. In each case it was a question of fact, and he was unable to say that the magistrates had gone wrong in taking the view that a nurseryman who was employed in this manner and with these privileges did not come within the expression "male servant" in section 19 (3) of the Revenue Act, 1869. He did not think that such an interpretation ought to be put upon the expression as to make it necessary to say that the Justices were wrong in holding that this man Taylor was not a male servant. The appeal must therefore be dismissed. Mr. Justice Hamilton and Mr. Justice Avory concurred, and the appeal was dismissed.

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 17.—There was a small exhibition at the meeting on Tuesday last, although a few of the exhibits were of outstanding merit. The FRUIT AND VEGETABLE COMMITTEE awarded a Gold Medal and a Silver gilt Hogg Memorial Medal respectively to two exhibits of Apples, but this body made no award to a novelty.

In the floral section, also, no new plant received an award, but there were showy groups of Carnations, Azaleas, greenhouse-flowering subjects, Alpines, Ferns and *Primula malacoides*.

Exhibits of Orchids were as attractive as ever, there being several splendid groups, as well as numerous novelties. A Gold Medal was awarded to Messrs. CHARLESWORTH & Co. for a miscellaneous collection, and the ORCHID COMMITTEE conferred one First-class Certificate, four Awards of Merit and two Botanical Certificates.

At the 3 o'clock meeting in the lecture room an address on "Weeds and Weed Seedlings" was delivered by Mr. H. C. Long.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and Messrs. H. B. May, Geo. Paul, W. P. Thomson, Chas. E. Pearson, Chas. E. Shea, J. T. Bennett-Poe, A. Kingsmill, G. Reuther, W. J. Bean, Jun., Green, Chas. T. Drury, W. B. Cranfield, Jas. Douglas, C. R. Fielder, J. E. McLeod, J. Jennings, W. Howe, H. J. Cuthbush, H. Turner, E. H. Jenkins, W. J. James, E. A. Bowles, Ed. Mawley, R. Hooper Pearson, Jas. Walker, R. C. Notcutt, Walter T. Ware, and J. H. Barr.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, filled a large table with indoor flowering plants and small Orange trees in fruit. There were many profusely-flowered plants of *Rhododendron (Azalea) indicum*, a big batch of *Camellias*, with a border of finely-flowered plants of *Freesia refracta alba*; sprays of *Acacia dealbata* in flower, and several mixed groups of blue and white-flowered plants, a combination exceedingly effective. The prettiest of these arrangements was one consisting of *Coleus thyrsoides* and *Eupatorium vernale*; another that was pleasing was *Exacum macranthum* intermingled with *Lily-of-the-Valley*. A plant of *Tillandsia Lindenii* attracted attention with a single blue flower developed from the centre of the flattened rachis. (Silver-gilt Flora Medal.)

Messrs. W. CUTHBUSH & SON, Highgate, showed a selection of Carnations, making a bright batch of colour. Amongst the novelties was Miss Winnie Hey, a yellow-ground Fancy, striped with red. Others that were noticeable included White Perfection, Countess of Bradford (yellow, marked with rose), Lady Miller of the Souvenir de la Malmaison type, the blooms being a shade of pink), Mrs. Fortescue (rose), Harlowarden (crimson), and Countess of Onslow (deep mauve with rose markings). The same firm also showed Alpines in a well-arranged exhibit and various greenhouse flowering and foliage plants. The Alpines included such pretty Irises as *I. Panfordii* (yellow), *I. alata* (blue), and *I. reticulata* (blue). At the back of the group were sprays of *Hamamelis arborea* in flower and *Pernettya* in fruit. There was a well-flowered specimen of *Rhododendron Nobleanum*, also many Indian Azaleas, *Daphnes*, *Lilium lancifolium*, *L. longiflorum*, *Astilbe (Spiraea) japonica* and other kinds. (Silver-gilt Flora Medal.)

Mr. H. BERNETT, St. Margaret's, Forest Road, Guernsey, showed Carnations of the perpetual-blooming type. The flowers were of remarkable quality, the colours being exceptionally bright. The large, cherry-red variety named Mrs. C. F. Raphael was especially good; we were informed that blooms are produced very freely; *Britannia*, *Orpheus* (a yellow-ground Fancy, lightly striped with carmine), R. F. Felton (pink), Countess of March (pink), Dorothy Gordon (cerise), Snow Queen (white) and Pluto (one of the best of the maroon-shaded sorts) were all shown well. (Silver-gilt Banksian Medal.)

Messrs. STUART LOW & Co., Bush Hill Park, Enfield, were the exhibitors of Carnations in variety, making a pleasing group. Princess Juliana is one of the firm's novelties, the colour is reddish-orange; the variety Lady Abington has pink flowers of a fine shade, the blooms being very sweet smelling; Marchioness of Lin-

lithgow is a white variety recommended for its freedom of flowering; *Admiration* is of a richer shade of pink than *Enchantress*; Baroness M. de Brehan has salmon-pink flowers, and is the result of crossing the variety Mrs. Burnett with *Winsor*. (Silver Banksian Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, were awarded a Silver Flora Medal for a collection of greenhouse Ferns. There were two remarkably fine specimens of *Asplenium caudatum*, each in a pot of 6 inches diameter only. Others of merit were *Davallia ornata*, *Cheilanthes elegans* (the Lace Fern), *Davallia epiphylla*, *Asplenium Nidus multilobatum*, and *Dicksonia squarrosa*. (Silver Flora Medal.)

Lady CHURCH, Woodside Place, Hatfield (gr. Mr. Robinson), staged a batch of *Cyclamens*, the plants being well flowered.

Mr. L. R. RUSSELL, Richmond, staged small but exceedingly well-fruited pot plants of *Citrus japonica*, many of the specimens having a dozen fruits. There was also a large batch of the yellow-fruited *Debregeasia velutina* in the centre of the group, which comprised, besides those mentioned, Azaleas, *Hamamelis arborea* in small pots, but well flowered, and *Antisia crenulata*, with bright red berries, like those of the Holly. (Silver Flora Medal.)

Messrs. THOS. S. WARE, LTD., Feltham, showed, on an improvised rockery, Alpine and hardy flowers. They were planted in batches, and included *Lathospermum tosarimifolium*, with dark blue flowers; *Moisia hypogea*; *Tussilago fragrans*, known in country districts as "Cherry Pie," from the sweetly-scented flowers; *Cyclamen Atknsii purpuricum*; *Primula*, *Kewensis*; *P. malacoides*; *P. Forbesii*; *Hellebores*; and *Primroses*. (Silver Banksian Medal.)

A large group of *Primula malacoides* in flower was displayed by Messrs. S. BIDE & SONS, LTD., Farnham, Surrey.

Mr. G. REUTHE, Keston, Kent, showed Alpines, including *Crocus Imperati piceus*, *Eranthis pinnatus*, *Callixene polyphylla*, and *Pycnela chlorantha*.

Messrs. JOHN PEEB & SON, West Norwood, exhibited Alpines in pans, some few, such as *Iris alata*, *Cyclamen Cornu C. ibericum*, *Milla uniflora*, and species of *Crocus*, being in flower.

The Misses ROBINSON, More Gardens, Shepperton-Thames, showed a small exhibit of hardy plants, including coloured *Primroses*, *Christmas-Roses*, and *Tussilago japonica* in bloom.

The GIFFORD HARDY PLANT NURSERY Co. again showed shrubby *Veronicas* and hardy flowering plants.

Messrs. BARR & SONS, King Street, Covent Garden, exhibited a few early-flowering bulbous plants, including *Snowdrops*, *Crocuses*, *Stillas*, *Freesias*, and *Iris reticulata*. At the back of the group were dwarfed trees in china pots, with sprays of *Garrya elliptica* and *Hamamelis arborea*, both in flower.

Messrs. W. WELLS & Co., LTD., Meisitham, exhibited blooms of the beautiful white Carnation named White House, and a crimson-coloured single *Chrysanthemum* named Kathleen May.

A new rose-pink Carnation of promise, named Coronation, was shown by Mr. BERTIE E. BELL, Castel Nursery, Guernsey.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshay, Henry Little, R. G. Thwaites, F. M. Ogilvie, W. Cobb, J. Cypher, W. H. Hatcher, A. Dye, C. H. Curtis, W. H. White, H. Ballantine, Guiney Wilson, W. Bolton, R. Brooman-White, H. J. Chapman, Stuart Low, J. Wilson Petter, John S. Moss, W. Waters Butler and Sir Jeremiah Colman, Bart.

Messrs. CHARLESWORTH & Co., Haywards Heath, were awarded a Gold Medal for a magnificent group having a frontage of about 60 feet, and in which the best showy Orchids of the season, both species and hybrids, were well represented, the leading kinds being grouped in batches, which gave a distinct character to the exhibit. In the centre were numerous varieties of hybrid *Odontoglossums*, the dark-blotched kinds being relieved by white forms of *O. ardensissimum* and *O. crispum*. On either side were plants of *Laelia anceps*, both white and coloured forms; *Laelio-Cattleya Ariel* of shades of yellow, hybrid *Calanthes* of various tints, *Cattleya Trianae* of good quality, scarlet *Odontodas*, a selec-

tion of *Cattleya Olive Dum. C. Emd. C.*, *Empress Frederick* with fine examples of *L. C. Bella alba*, a number of well-flowered plants of *Vanda Amsonia* with *Lycaste Skinneri* and its variety *alba*, various rare *Cypripediums*, including the new *C. Alameda*, *disigne Barefield Hall* × *Alcibiades superbum*, a noble flower finely marked. Others of note included a profusely-flowered *Saccolabium bellianum*, *Odontoglossum Ernestii*, a distinctly-marked hybrid; the white *Saccolabium Harrisianum*, and a pleasing lot of *Masdevallia tovarensis*.

Mrs. NORMAN COOKSON, Oakwood, Wyham (gr. Mr. H. J. Chapman), was recommended a Silver gilt Banksian Medal for an interesting collection of hybrid Orchids, all raised at Oakwood, and including *Cypripedium Kenneth durstissimum* × *Calypso*, with the greater part of the dorsal sepal of deep claret colour; *C. Venus grandiflorum*, a larger form of the fine, white, purple-spotted hybrid previously shown; *C. Oakwoodiense*, an attractive flower, and other *Cypripediums*; *Odontoglossum crispum* Chapmanii, finely blotched, raised from varieties of *O. peacultum*, *O. Cooksonii*, and *O. Cook-omanum*; *Cattleya Chapmanii* (Triana × Hardyana), good in form and bright in colour; several new seedling *Odontoglossums*; the remarkable light-coloured *Cypripedium Regina* (*Lecanum Chukaberianum* × *Fairbairntoni*), and the very hardy, some *Odontodia Bradshawii* Cookson's variety.

Sir JEREMIAH COLMAN, Bart., Gattos Park (gr. Mr. Collier), staged a select group, two of the plants receiving awards. Others noted included the singularly fringed *Bulbophyllum Dayanum*, the fragrant, white-flowered *B. auricomum*, *Phorolithallis Scapha*, *Masdevallia polystachya*, and a good plant of *Cypripedium Helen H. Gattos Park variety*, the large, white flowers being marked with small, purple spots.

R. G. THWAITES, Esq., Chessington, (Christ Church Road, Streatham) (gr. Mr. J. M. Black), was awarded a Silver Flora Medal for a pretty group of hybrids. Novelties comprised *Cattleya Blacki Mendelii alba* × *Gaskelliana alba*, of which several forms were shown with nearly white flowers, more or less flushed with pink; two good specimens of *C. Octave Dum.*, one with very dark flowers; *C. Laelia Perivahona* × *aurora*, hybrid *Odontoglossum* and *Odontodas*, including the new *Odontodia Zephyr*, *C. Noezliana*, *O. Wilkeanum*, a bright red marked flower not yet mature. The Medal was afterwards withdrawn by the Council and a Vote of Thanks substituted.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for an excellent group, in which the forms of *Cattleya Trianae* were well represented, the finer being *hyacinthifolia*, *Centurion* and *Breadbought*, all with very handsome flowers, the last named being a model bloom of a silt rose colour with crimson-purple front to the lip. The group also contained a fine show of varieties of *Laelia anceps*, hybrid *Calanthes*, and *Odontoglossums*, among which was the new *O. Ophir* (Edwardii × *crispum* Harvanum), the flowers being purplish-ochraceate, tipped with rose and with a distinct yellow crest; also *O. Noble elegans* × *ardensissimum*, with an elegant spray of white flowers blotched with dark purple; *Laelio-Cattleya Goldfinch*, *Brasso-Cattleya Thomsonii*, and various other hybrids were also shown, including the pretty *Cypripedium Charles Sladden* (see Awards).

Messrs. STUART LOW & Co., Bush Hill Park, Enfield, received a Silver Flora Medal for a varied group, at the back of which *Laelia anceps* varieties and good plants of *Dendrobium Wardianum* were effective. They also showed a selection of *Cypripediums*, the best of which was *C. Memoria Jerninghamiae*, a flower of fine substance and effective dark colour. Others noted were *C. Mimos Youngii*, *C. Mous. de Certe* Symburne's variety, *C. Euryades splendens*, *C. Schlimii*, *Oncidium ranunculoides*, *Odontoglossum blandum*, some pretty hybrid *Odontoglossum* and *Sepbro-Cattleya Saxa*.

Messrs. J. & A. A. McLEAN, Cooksbridge, were awarded a Silver Flora Medal for a neat group of splendidly-grown plants of *Laelia anceps*, the finest being the white *L. a. Schiediana*, of which there were several spikes, one with five blooms; *L. a. alba*, all with pure white flowers, and its variety *Distinction*, with thin blue lines on the side lobes of the lip; *Cattleya Octave Doia*, *C. Emd.* the violet-lipped *Zygopetalum Penenonkii*, various good *Odontoglossum*, including a fine hybrid *Laelia Flaryana*, and

and Hallii; bright Calanthes, and a selection of Cypripediums, including the massive C. Beryl, with very broad petals and finely-spotted dorsal sepal; C. aureum giganteum, and a fine hybrid between C. Euryades and C. Beekmanii.

Messrs. J. CYRER & SONS, Cheltenham, received a Silver Flora Medal for a good group, consisting principally of Cypripediums, including some effective unnamed hybrids. The more noticeable were C. Leeannum Chardwar, a flower of unusual colour; the pretty light-coloured C. Felicity; C. Beekmanii; C. Graceæ; C. Curtmannii; C. Thompsonii; varieties of C. Actæus, and C. aureum. With these were arranged hybrid Calanthes, the pretty Epidendrum polyblum, and a selection of Odontoglossums.

Mr. E. V. Low, Vale Bridge, Haywards Heath, was awarded a Silver Flora Medal for a good group, all the plants being remarkably well grown. Amongst those of special note was a fine plant of Cattleya Percivaliana alba of the best type and an extremely rare Orchid. Among the Cypripediums was the new C. Ulysses, a neat and well-formed flower of a greenish-yellow ground colour, effectively marked with chocolate-purple, and with a shining surface; also C. Amboyana (Fairrieanum × Dulcinianum), with a large, white dorsal sepal, having greenish lines and a light-rose tint, the petals being spotted with dark reddish-purple.

Messrs. MANSSELL & HATCHER, Rawdon, Yorkshire, staged a small but attractive group, for which a Silver Banksian Medal was awarded. Noteworthy species were Arachnanthe Cathartii, now seldom seen, with a large, red-barred flower; Eria stellata gigantea, with strong spikes of star-shaped white flowers; several specimens of Vanda Amesiana; the typical Brassavola nodosa, and several good Odontoglossums, including a distinctly-blotched form of O. crispum. Among the Cypripediums were C. aureum virginale and Vine House variety, C. Kitty Measures, a pleasing flower with a strong indication of C. Spicerianum in its parentage; and C. Thalia Mrs. Francis Wellesley, still the finest of its class.

EDWARD ROBERTS, Esq., Park Lodge, Eltham, was awarded a Silver Banksian Medal for a group of hybrid Cypripediums, the best of which was C. May Roberts, a supposed cross of a fine form of C. insigne with C. Actæus, and resulting in a large, bold, well-marked flower.

Mr. G. W. MILLER, Clarkson Nurseries, Wisbech, was awarded a Silver Banksian Medal for a group of Cypripediums, Lælia anceps, Calanthes, and other kinds.

Monsieur MERTENS, Ghent, showed a few hybrid Odontoglossums.

Mrs. GEOFFREY LUBBROCK, Broadoaks, West Byfleet (gr. Mr. J. B. Lowe), was awarded a Silver Banksian Medal for a group of well-flowered varieties of Dendrobium nobile.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed Cypripedium Princess Louise, supposed to be a cross between C. Leeannum giganteum and C. Druryi, or C. Buchanannum (Druryi × Spicerianum), probably the latter. The flower in its form, and much of its colouring, has a close resemblance to the fine C. Leeannum "J. Gurney Fowler," and especially in the uniformly squared, white dorsal sepal. C. Cupid magnificum, a larger form of the pretty, white hybrid with purple spotting shown previously, and Sophro-Cattleya "Mrs. Francis Wellesley," a well-formed flower of good size, tinted with salmon-rose colour.

Messrs. HATH & SONS, Cheltenham, staged a group of Cypripediums.

Mr. J. HAWKES, Osterly Park, Isleworth, displayed two twin-flowered spikes of Cypripedium insigne.

H. S. GODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), staged two examples of Odontoda Latetia and O. Cooksonia.

G. P. WALKER, Esq., Putney Heath (gr. Mr. M. Grogan), showed Brasso-Lælia, Mrs. G. P. Walker (L. flava × B. glauca), with yellow flowers.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cypripedium Elizabethæ var. Vogel (Hera Marica × Habkiana), from Mons. FRON'S LAMBLAU, Brussels.—A fine Cypripedium, with much of the effective claret-purple spotting seen in C. Hera Euryades on the broad, white dorsal sepal. The petals and lips are Cowslip yellow, tinged and slightly veined with purple. The

name, however, is a repetition of the C. Elizabethæ (Lawrenceanum × Parishii) R. H. Measures, therefore some distinctive title should be adopted. Under the circumstances it might be called C. Vogelzand.

AWARDS OF MERIT.

Odontoglossum Halsyanum (parentage unrecorded), from J. GURNEY FOWLER, Esq., Gledelands, South Woodford (gr. Mr. J. Davis).—A showy hybrid, suggesting in the rich purple blotching of its pure white flowers a fine blotched form of O. crispum, which was probably one of the plants. The white, purple-marked lip, however, plainly indicates hybridity. The plant had a spike carrying a dozen large blooms.

Odontoglossum Rosefieldiense (Harriganum × Lambauium), from DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables).—One of the happiest combinations yet made, resulting in a model flower, broad in all the segments, richly coloured, but with the colouring broken up sufficiently with thin lines of the white ground, and with a very broad ovate white lip, prettily marked with reddish purple around the yellow crest. The blotching on the sepals and petals is of a reddish claret colour, but when seen with the light behind there is a crimson tint, and in the shade a trace of violet. In thus improving on the handsome O. Lambauium, good work has been accomplished.

Cypripedium Charles Studdin (glaucophyllum × bellatulum), from Messrs. SANDER & SONS, St. Albans.—A pretty hybrid of dwarf habit and with well-rounded flowers that are superior to any of the C. Chamberlainiana crosses, although C. glaucophylla is a near ally. The ground is white, the petals and dorsal sepal being closely veined with claret colour and tinged with rose between the veining. The lip is closely spotted with small, claret-purple dots.

Odontoglossum Golmanii (Edwardii × Bolfa), from F. DU CANE GODMAN, Esq., South Lodge, Horsham.—A pretty hybrid, with a dwarf spike of rose purple flowers and yellow crest. In habit it is superior to most of the O. Edwardii crosses. The colour also is brighter than some forms.

BOTANICAL CERTIFICATES.

Bulbophyllum goblinum, from SIR JEREMIAH COLMAN, Bart., V.M.H., Gutton Park (gr. Mr. Collier).—A singular and pretty species allied to B. Reinwardtii; the sepals and narrower petals are pale green, with a few purple markings. The beauty of the flower lies in its large, fleshy, hinged labellum, which is ruby-crimson in colour.

Phoroglottis javanica, from SIR JEREMIAH COLMAN, Bart.—A singular species, with broad, stalked leaves and erect inflorescence, 1½ foot in height, and bearing many singularly formed flowers arranged spirally.

Fruit and Vegetable Committee.

Present: G. Bunyard, Esq. (in the Chair); and Messrs. C. G. A. Nix, P. D. Tuckett, W. Bates, A. Dean, G. Woodward, E. Beckett, G. Kelf, H. Markham, G. Reynolds, O. Thomas, G. Wythes, W. Poupard, A. R. Allan, J. Lyne, P. C. M. Veitch, J. Gibson, J. Jacques, and W. Crump.

Eight varieties of forced Asparagus, in small bundles, were presented from the Society's Wisley Gardens. Five of these showed precocity of some 10 to 14 days over the other three, but these latter had the stouter stems. It was decided to inspect them again in the spring.

Messrs. JAS. VEITCH & SONS, Chelsea, exhibited a superb collection of Apples, having 100 distinct dishes. The fruits were very clean, of good size, and firm. A selection of the choicer fruits of cooking varieties included Hambling's Seedling, Sandringham, Annie Elisabeth, Warner's King, Bismarck, Alfriston, Newton Wonder, King of Tompkins' County, Lane's Prince Albert, Lord Derby, Northern Greening, Withington Fillbasket, and Beauty of Kent; of dessert sorts, there were excellent samples of Blenheim Pippin, Rosemary Russet, Bowhill Pippin, Court pendu-plat, Baxter's Pearmain, American Mother, Melon Apple, Lord Burghley, Cornish Aromatic, Rival, Claygate Pearmain, Cox's Orange Pippin, and Adams' Pearmain. (Gold Medal.)

Messrs. G. BUNYARD & Co., Maidstone, had also a fine exhibit of some 120 dishes of Apples, Tower of Glamis, Beauty of Kent, Striped Beefing, Golden Noble, Royal Jubilee, Warner's

King, Lord Derby, Gloria Mundi, Byford Wonder, Lane's Prince Albert, Stirling Castle, and Bramley's Seedling, all culinary varieties, were specially fine. Good dessert fruits were seen in September Beauty, Winter Nonesuch, Winter Ribston, Cox's Orange Pippin, American Mother, Wealthy, King of the Pippins, Lord Hindlip, Barnack Beauty, and Mabbott's Pearmain. There were also a few Pears, including Uvedale St. Germain, Verulam, Marie Benoist, and Belle des Arbres. (Silver-gilt Hogg Memorial Medal.)

Messrs. W. SEABROOK & SONS, Chelmsford, staged a collection of some 36 baskets and dishes of Apples, all excellent samples. New Hawthornden, Royal Jubilee, Golden Noble, Bismarck, Bramley's Seedling, Lord Derby, Newton Wonder, Beauty of Kent, The Queen, Alfriston, Stirling Castle, Lane's Prince Albert, Cox's Orange Pippin, Rosemary Russet, Claygate Pearmain, and Melon Apple were specially good. (Silver Knightian Medal.)

Messrs. SUTTON & SONS, Reading, staged a collection of solid white heads, both trimmed and untrimmed, of Superb Early White and Winter Mammoth Broccoli. (Silver Banksian Medal.)

THE EDUCATIONAL AUTHORITY OF MONMOUTHSHIRE showed a collection of 146 varieties of Potatoes in baskets, from extensive trials conducted at two centres in that county. Voluminous reports, which may be published in the Society's *Journal*, gave particulars of the trials. (Silver Knightian Medal.)

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

JANUARY 19.—The 71st annual meeting of the supporters of this gardening charity is being held at Simpson's Restaurant, Strand, as these pages go to press, under the chairmanship of the treasurer and chairman of committee, Mr. Harry James Veitch.

The annual report, read by the secretary, Mr. George Ingram, shows that good work has been done during the past year, and that the committee is hopeful for the future. The number of gardeners and gardeners' widows seeking relief is greater than ever. Seventy-three names were included on the list of voting papers, and the circumstances of each candidate were first considered carefully by the Executive Committee. Of this number the Committee, at the time the ballot papers were issued, were only in a position to recommend the election of 20.

RESULT OF ELECTION.

	Age.	No. of Votes.
Plummer, Arthur	69	4,062
Baillie, Wm. M.	69	3,162
Butters, Susannah	67	3,030
Sutton, Thomas	74	2,943
Gidley, Thomas C.	76	2,832
Boothroyde, George	74	2,816
Chinnoy, Sarah	65	2,780
Watson, Rebecca	62	2,746
Richards, Emily	60	2,729
Birch, John	69	2,716
Gough, John	78	2,656
Bury, Emily	77	2,607
Dallimore, John	71	2,585
Arnold, Emma	67	2,577
Bastin, George	73	2,576
Sutton, Sarah A.	73	2,516
Cavill, Reuben	73	2,457
Hope, Mary	80	2,446
Robinson, William D.	67	2,423
Searing, Anne	60	2,420

Pensioners Elected after the Poll.

- *Gedge, George (61).
- *Rosam, Henry J. (45).
- †Dunstall, David (48).

* These candidates were elected by the annual general meeting by virtue of the privilege given the Committee in Rule III., Clause 10. They fill places rendered vacant by deaths which have occurred since the ballot papers were issued.

† This candidate was selected to receive a year's pension (£20) kindly given by Mr. Arthur W. Sutton.

Mr. George Monro intimated his desire to give a sum of £10 to the unsuccessful candidate Marie Baillie.

ROYAL CALEDONIAN HORTICULTURAL.

JANUARY 11.—The annual general meeting of the Society was held in Dowell's Rooms, George Street, Edinburgh, on this date. Mr. J. W. McHattie, the senior vice-president, occupied the chair.

It was announced that King George V. had consented to continue to afford the Royal patronage to the Society.

The report of the Council showed that there was a surplus of revenue over expenditure on the year's working of £79. The spring show, however, resulted in a serious loss, and but for the increase in the receipts at the September show, there would have been a deficit.

It was reported that the Neill Prize for the biennial period to May 15, 1910, had been awarded to Mr. Alex. McMillan, whose work in hybridising Rhododendrons was well known.

The suggested amalgamation with the Scottish Horticultural Association presents several difficulties. There is no possibility of the Society being able to surrender its charter with a view to amalgamating with the other society under an ordinary constitution, and the only other alternatives are (a) for the Scottish Association to join this Society under its present charter, or (b) for both societies to join under a new charter. The committee rejected the first proposal, and the other, it was pointed out, would be seriously expensive.

The following office-bearers for 1911 were elected:—Mr. J. Stewart Clark, of Dundas, president (re-elected); Mr. Wm. Younger, Ravenswood, Melrose, vice president; Messrs. James Whytock, Dalkeith Gardens, W. H. Massie, 1, Waterloo Place, Edinburgh, and Geo. P. Berry, Edinburgh and East of Scotland College of Agriculture, councillors.

STIRLING CHRYSANTHEMUM.

JANUARY 14.—The annual general meeting of this society was held in Stirling on the above date. The President, Mr. H. Kinross, occupied the chair. The annual report and balance-sheet were submitted and unanimously adopted. The finances showed a deficit of more than £6. The secretary and treasurer, Mr. R. C. Dickson, resigned these offices, and, on the motion of the chairman, he was thanked heartily for his past services. The officers were appointed, Captain Stirling of Keir being elected as hon. president; Mr. Henry Kinross, president; Mr. George Petrie, secretary; and Mr. Thos. Carson, treasurer.

NATIONAL CHRYSANTHEMUM.

JANUARY 16.—A meeting of the Executive Committee was held at Carr's Restaurant, Strand, on the above date, when Mr. Bevan presided. The dates of the Society's 1911 exhibitions were provisionally fixed, subject to arrangements with the Crystal Palace authorities. The draft annual report for the past year was passed for presentation at the annual meeting. The balance-sheet also was considered, after being duly audited. It was proposed by Mr. Ladds, and seconded by Mr. Oliver, that a conference be held towards the close of the year, the date and subjects for discussion to be settled later. The annual meeting was fixed for February 6, at Carr's Restaurant.

NATIONAL SWEET PEA.

JANUARY 18.—A special general meeting of this society was held at the Hotel Windsor on the above date, for the purpose of considering the constitution of the Floral Committee. Mr. G. W. Leak occupied the chair.

The Chairman proposed "that the instruction given to the General Committee as to the definition of amateurs" be rescinded. This was seconded by Mr. E. F. Hawes. Much correspondence dealing with the matter was read by the Secretary, and a discussion ensued, in which Messrs. Breadnora, A. Dean, G. Gordon, S. B. Dicks, W. Deal, and others took part.

On the motion being put by the Chairman, it was declared carried by 43 votes to 4.

The Chairman further proposed that the society should define an amateur in accordance with the regulations of the Royal Horticultural Society. Mr. Robert Sydenham seconded the motion. After discussion, the following amendment was moved

by Mr. J. G. Baker:—"That, as there are at present no rules for the formation, composition, and conduct of a Floral Committee, this meeting requests the General Committee to draw up rules for such purpose and submit the same to a special general meeting of the society in April, 1911. Such rules, when passed by the special meeting, shall become operative immediately." This was seconded by Mr. F. H. Chapman.

An additional amendment was proposed by Mr. H. Hesford, and seconded by Mr. T. Want, with regard to the R.H.S. definition of an amateur; but this was defeated. The original amendment, proposed by Mr. Baker, was then put to the meeting, and carried unanimously. The result reopens the whole question of the constitution of the Floral Committee, and the subject will be considered by the General Committee without delay.

Obituary.

GEORGE BLAKE.—The recent death of Mr. George Blake, in his 92nd year, severs one of the few links that remain between the present and the International Horticultural Exhibition of 1866. Blake, who was gardener at the time of that exhibition to Robert Warner, Esq., Bloomfield, Chelmsford, won the first prize in the premier class for Orchids, namely, the class for 50 Exotic Orchids, of any kind in flower. The prizes offered were: 1st, £50; 2nd, £15; and 3rd, £10. The judges were

THE LATE GEORGE BLAKE.
(Winner of the Premier Orchid Class in the 1866 Exhibition.)

Professor Reichenbach, Hamburg; Mr. Anderson, Meadow Bank; Mr. Lawrence, Farnham; and Mr. W. Rollisson, Tooting. Robert Warner was one of the celebrated Orchid growers of that date, and he possessed one of the most complete collections. It may be interesting to enumerate the 50 specimens which won the prize at the '66 show. These were as follow:—

Aërides Fieldingii.	Dendrobium densiflorum.
" virens.	" giganteum.
Cattleya Mossiae (5).	" macrophyllum.
" " elegans.	" nobile.
" " fimbriata.	Lælia cinnabarina.
" " flammea.	" purpurata.
" " Lawrencei.	" Schilleriana.
" " [ana.	Odontoglossum citrosimum.
" " lobata.	" Karwinskii.
" " marmorata.	Oncidium amphatum majus.
" " Napoleonis.	" sphacelatum.
" " purpurata.	Phajus Wallichii. [majus.
" " Rothschildii.	Phalaenopsis amabilis (2).
" " [ana	" grandiflora (2).
" " Skinneri (2).	" [aurea (2).
Chysis Iavis.	" Schilleriana.
" Limninghii.	" intermedia var.
Cypripedium barbatum.	Trichopilia crispata. [Portei.
" " super-	" tortilis.
" [bum.	Vanda insignis (2).
" hirsutissimum.	" suavis (3).
" Hookeræ.	" tricolor.
" villosum.	" " superba.
Dendrobium crepidatum.	" " formosa.

George Blake was born in Wokingham in Berkshire. His father and grandfather were sawyers and woodcutters. At the age of 13, he hired himself to a farmer at Slough. His first employment in a garden was quite accidental, for in the ordinary discharge of his duties, he had occasion to drive a cow from Slough to a gentleman at Waudsworth, and this gentleman invited Blake to come to him as a gardener's assistant at the end of his hiring term. Blake accepted the invitation, and stayed at Waudsworth for a period of two years. Then he went to an Orchid cultivator, Mr. Ruckers, as under gardener to a Mr. Milan. He remained with Mr. Ruckers eight years; and years afterwards he often referred to that period as being the happiest of his life. Blake next had charge of Mr. Schroder's collection of Orchids at Stratford, and won several prizes at the exhibitions for collections shown from Mr. Schroder's garden. After seven years, he removed to a Mr. Tukey, of Hitchin, and subsequently, on the recommendation of the late Benjamin Williams, of the Upper Holloway Nurseries, Blake was appointed gardener to Robert Warner, whom he served for seven years, and, as stated above, this period covered the 1866 exhibition. On leaving Bloomfield, Blake was appointed gardener to John Offin, Hutton Park, Brentwood. He stayed in that situation for 24 years, during which time he served under three employers. For the last 14 years of his life, deceased lived with his eldest son at Earl's Colne, Essex. He leaves two sons, whose combined ages are 91 years.

JOHN FOX.—The superintendent of the famous park of Prince Henkel of Donnermark, in Neudeck, Upper Silesia, Prussia, died on December 15, at Tauswitz, aged 70 years. Deceased first entered the employ of the Prince of Donnermark in 1867. He knew neither a word of German nor Polish (Polish being the language of that part of Prussia). The site of the park was mere bog land. It was first drained, and then laid out by Fox in the English style. The park is so beautiful that it has formed a model for many others in Germany and Poland. An Irishman, Fox got on well with his German and Polish colleagues, being esteemed highly by all of them. He was awarded the honorary title of "Director of Landscape Gardening" (Gartenbau Director) by the Prussian Government.

JAMES SEATON.—The many friends of Mr. Jas. Seaton will learn with deep regret of his death, which occurred at Lewisham on the 1st inst. Born at Blair Atholl, N.B., 75 years ago, he entered on a gardening career directly upon leaving school. He was employed in some well-known Scottish gardens, amongst others those of St. Martins, Perth, Methven Castle, in the same county; and King's Meadows, Peebles. He proceeded south whilst still quite a young man, and served as foreman in several gardens in Surrey and Kent. In the late 'sixties, Seaton entered the then well-known nurseries of Messrs. Osborne at Fulham, but the post of head gardener at Mount Clare, Rechempton, being offered him, he transferred his services there, and soon made a name for himself as a first-rate Peach grower. The crops borne by the Mount Clare Peach trees which Seaton had planted were amongst the most noted examples in the country. Deceased, who was unmarried, was of a very quiet, retiring nature, rarely mixing even in the company of gardeners.

- JOHN R. HAMILTON, Waltham Cross, Hertfordshire—Insecticide.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 14, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather.—The general character of the week was unsettled, rain falling at times in most localities during the earlier days, and sleet or snow over a large portion of the Kingdom later. Precipitation became, however, much less general after the middle of the period. Aurora was seen in Scotland on the night of the 8th, and a thunderstorm occurred at Newcastle-on-Tyne late on the 12th.

The temperature was below the average in Ireland, England S.W. and the English Channel, but above it in all other districts. The divergence from the normal was nowhere very large. The highest of the maxima occurred on the 8th at most stations, and varied between 50° in England E. and in Scotland N. and W., and 54° in Ireland S. The lowest of the minima, which were recorded towards the end of the week, ranged from 22° in Scotland W. and 23° in England E. and in Ireland to 29° in Scotland N., and to 33° in the English Channel. The lowest grass readings were 12° at Newton Kigg, 14° at Tunbridge Wells, 15° at Aspatia, and 17° at Luton, Southport, Llangunnaugh Wells and Armagh.

The mean temperature of the sea was lower in most places than during the corresponding week of last year. The values ranged from between 47° and 49° on some parts of the south-west coast of England to less than 42° on the east and north-east coasts generally, and to 3°·6 at Croyarty.

The rainfall was less than the average in Ireland and England S.W., and about equal to it in England N.W. and the Midland Counties. Elsewhere there was an excess, but the difference from the average was not as a rule large. At Portlaoich 1·38 inch fell on the 10th, at Fort William 1·17 inch, and at Aspatia 1·04 inch.

The bright sunshine exceeded the average in all districts except Scotland N. The percentage of the possible duration ranged from 31 in England S.W. to 19 in England N.E., and to 10 in Scotland N.

THE WEATHER IN WEST HERTS.

Week ending January 18.

The longest dry period for over three months.—The last 11 days have, with one exception, been more or less unseasonably warm. On the other hand, four of the last six nights were below the average in temperature, and on three of these the exposed thermometer registered 13° of frost. On the last night of the week the same thermometer, however, did not fall below 37°, which is 10° higher than is reasonable at this the coldest period of the year. The ground is now 1° colder than is reasonable at 2 feet deep, and at about an average temperature at 1 foot deep. Some rain fell on each of the first 12 days of the month, but to the total depth of only 14 inch. Since then the weather has been dry. No rain has now fallen for five days, making this the longest spell of dry weather since the early part of October—of for over three months. On the morning of the 13th inst., the ground for the first time this winter was nearly covered with snow. There has been more or less circulation through both of the soil gauges during the week, but the amounts the last few days have been small. The sun shone on an average for 2 hours 33 minutes a day, which is an hour a day longer than the average duration for the middle of January. On two days the sun shone for over five hours a day, whereas on three other days had, taken together, less than 20 minutes sunshine. On the first day of the week the wind was rather high, but since then light airs and calms have alone prevailed. The mean amount of moisture in the air at 3 o'clock in the afternoon fell short of a reasonable quantity for that hour by 3 per cent. E. M., Berkhamsted, January 18, 1911.

ENQUIRY.

MICE AND RHUBARB.—Can any reader inform me if mice eat Rhubarb plants? I find the crowns of Rhubarb in these gardens are eaten by some creatures, apparently mice, although we cannot catch any of these rodents. E. W.

The Editors will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for reproduction in this Journal.

APPLE SHOOTS FOR EXAMINATION: R. J. F. The shoot was attacked by the Apple scab fungus. Remove and burn all the dead branches, and then spray the trees with the Bordeaux mix, the next spring when the leaves are half grown.

FRENCH BEANS: Mrs. Marfic. Kindly send specimens for examination.

COMPLAINING IN AUSTRALIA: S. R. There are but few openings for private gardeners in Australia, although cultivators for market purposes are welcomed by the authorities. As it is your intention to do so ultimately in the market work,

there should be a favourable inducement for you to emigrate. You will find a note on the subject by the late James McIndoe in the issue for May 16, 1908, p. 324.

HONEY-FLOWER: B. This name is applied to Melanthus major and sometimes to Protea melthera.

INSECTS ON BEANS AND IN SOIL: C. J. M. The "grubs" are a species of cheese mite (Tyroglyphus siro), and were undoubtedly introduced with the bones. They are not known to be destructive to plant life, and will probably disappear in the course of time.

INSECTS ON FERNS: W. M. H. The small white objects are the pupa cases of the males, the larger brown ones those of the females of a species of scale insect (Chionaspis aspidistræ). There are also a few young forms of a mealy bug (Dactylopius citri). You can keep these pests in check by sponging the leaves frequently with a soap emulsion.

MOSCHOSMA RIPARIUM: A. B. C., Trowarthenick. This greenhouse plant is a comparatively recent introduction to gardens. It was described by Hochstetter in 1845, but little was known of it till 1900, when it was referred to by Baker in the Flora of Tropical Africa. In the early part of 1902 Messrs. James Veitch & Sons, Ltd., exhibited specimens at the meeting of the Royal Horticultural Society, and a sketch from these plants appeared in Gardeners' Chronicle, February 22, 1902, fig. 35. As Nicholson's Dictionary of Gardening was published before 1886, it is not surprising the plant is not mentioned in that work. Fearing as it does a valuable winter blooming greenhouse shrub, Moschosma riparium soon became popular, and it is now in general cultivation.

MUSHROOMS DISEASED: Start. The trouble is due to a minute parasitic fungus—Hymomyces perniciosis. If the crop is badly affected, it will be advisable to remove the bed at once, otherwise the spores may infect the house to such a degree as to be difficult to eradicate. Before making up a new bed, spray the interior of the house thoroughly three times, at intervals of 10 days, with a solution of copper sulphate, at the rate of 1 lb. of the chemical in 15 gallons of water. During the intervals of spraying, keep the house moist and warm, to favour the generation of the spores.

NAMES OF FRUITS: T. Murray. Muchall Crab.—H. Symonds. 15. Beurre d'Esp. 41. Uvedale's St. Germain; 76. Cattilac; 82. Née Plus. Meims.—H. Shaw. Norfolk Stone Pippin.—J. W. I. decayed; 2. a fine fruit of Josephine de Malines.

NAME OF PLANTS: H. T. Ornithogalum lacteum. (See p. 26 in the last issue).—Advance. 1. Begonia polyantha; 2. Cyrtopodium venustum; 3. C. Leeannum var.; 4. Begonia fuchsioides; 5. Adiantum Capillus veneris var.; 6. Asparagus crispus.—F. E. 1. Bifrenaria aurantiaca; 2. Brassia maculata; 3. Cyrtopodium ornithum; 4. Cyrtopodium Calypso; 5. Cochlidia sanguinea.—J. W. S. 1 and 2, varieties of Cyrtopodium Lathamianum (villosum = Spiciferanum); 3. Cyrtopodium Calypso (Boxalli = Spiciferanum); 4. Cyrtopodium nitens superbum.—J. B. 1. Dichorisandra vitata; 2. Dracena Godsealiana; 3. Dracena Golden; 4. Paulinia thalictrofolia; 5. Asparagus virgatus; 6. Aristolochia elegans; 7. Streptosolium Jamesoni; 8. Furcraea longeva.—Amateur. Obantoglossum Andersonianum, of small value.

PELAGONIUMS DISEASED: D. R. The cuttings have been taken from diseased stock that has been attacked by Botrytis. There is no cure.

ROSE FROM KARL DRUSCHKE: A Reader. If your plant was only lifted from the open this season, it will need very steady forcing, but may succeed in your cold house. It is always better to use established plants for early forcing. Molly Shanman Crawford and Lady Quarles Ewart are excellent white Roses for forcing.

SMALL RANGE OF UTILITY GREENHOUSES: D. H. J. Unless you prefer to have a three-quarter span house, the cost of erecting a full span house would be very little, if, indeed, more than that incurred in the erection of the three-quarter span. The increased space and additional light which the span house would afford would be a great advantage. In your

case the rafters on the south side of the house (which would run nearly east and west) should be a trifle longer than the rafters used on the opposite side to make up for the fall in the ground. The end and side walls should, in the event of your having a sunken pathway as shown in your sketch plan, be about 18 to 24 inches high, and built of 4½-inch brickwork with 9-inch piers (showing outside) at intervals of about 8 feet. Rafters 7½ feet in length will be ample for a house 12 feet wide. The rafters on the south side may be 7 feet 9 inches long, and those on the other side 3 to 6 inches shorter. If they are fixed at 18 inches apart, it will admit of panes 18 inches wide of 21-ounce glass being employed for glazing. Bed the glass in good white-lead putty, and secure the individual panes on the top with small brass nails such as are used by shoemakers, employing four to each pane. Provide for six roof ventilators on either side of the house. These should be secured to the ridge board by suitable hinges; those on one side of the house being fixed anglewise to those on the opposite side, in order to secure a regular admission of fresh air to the house. If the ventilators are worked by Wooland's continuous ventilating gear, a great saving of labour will be effected. Construct the stoke hole at the lowest end of the range, and this must be sunk sufficiently to admit of the boiler being fixed low enough to allow of a gradual rise in the flow pipes. Due allowance must also be made for a rise in the main flow pipe extended to the end of the pit, which, according to your sketch, is situated on a lower level than the proposed greenhouse. A throttle valve should be fixed in each flow pipe where it enters the house or pit to regulate the circulation of the hot water. Four 2-inch pipes would be ample to heat the pit; diminishing pipes with 2-inch throttle valves attached to same may be taken from the 4-inch main. You must provide an air pipe in the end of each flow pipe at the highest end in both house and pit. The supply cistern will also be better attached to one of the return pipes at the farthest end of the house from the boiler, the air pipes being extended slightly above the top of the supply cistern. The rafters may consist of yellow deal 1½ inch by 3 inches, end rafters 3 inches by 4 inches, wall and end plates 4 inches by 5 inches. An ordinary No. 2 wrought-welded saddle boiler capable of heating 400 feet run of 4-inch piping would answer your purpose, and would also be powerful enough to heat a second pit or house should you decide to erect one at some future date.

VIOLETS UNHEALTHY: J. W. P. Excess of moisture first caused the edges of the leaves to decay, and then fungi settled on the decayed portions. Afford an increased amount of ventilation.

WHITE OBJECTS ON LEAVES: J. T. These are the cocoons of a minute insect belonging apparently to the Psocida or "Book lice"; they are not known to be injurious to vegetation, and they feed largely, it is supposed, upon decaying vegetable matter. Remove the dead leaves and destroy them.

WILLOW TIMBER FOR CRICKET BATS: Correspondent. All the three specimens you send are badly matured shoots of Salix alba, and most probably S. a. corula. It cannot be determined from such poor specimens whether they are the vigorous form (considered by Dr. Henry to be a hybrid between S. alba and S. fragilis) grown for bat making. All three specimens could be matched from a single tree, which would probably furnish others still more distinct. If the trees are of a large size that would be good evidence they are of the right type. The intermediate hybrid (S. viridis, Fries), is of no service for bat-making, and is not included amongst your specimens.

THE COMING OF EVOLUTION.*

THE Syndics of the Cambridge University Press are to be congratulated on being able to include this remarkable book among the earliest volumes of *The Cambridge Manuals of Science and Literature*. It is not easy to write a book with such a title as *The Coming of Evolution*—a title suggesting the re-telling of an oft-told tale—which will at once strike the reader as essentially fresh and original; yet this is what Mr. Judd has accomplished. The book's most striking characteristic is its broad interpretation of what is meant by "evolution." This word is applicable, not merely to the gradual development of the forms of life on the earth, but also to the changes that time has wrought on the fabric of the globe; in other words, it means continuity, inorganic as well as organic. We do not claim that this point of view is fresh. It is, however, a view which writers on evolution have too much neglected, and Mr. Judd, by his masterly treatment, has, we repeat, given a striking freshness and vitality to his subject. In Huxley's chapter, "On the Reception of the Origin of Species,"† we find

briefly given what is practically the thesis of Mr. Judd's book, not only as regards evolution, but also touching the relation between Lyell and Darwin. "I cannot but believe that Lyell, for others, as for myself, was the chief agent in smoothing the road for Darwin. For consistent uniformitarianism postulates evolution as much in the organic as in the inorganic world. The origin of a new species by other than ordinary agencies would be a vastly greater 'catastrophe' than those which Lyell successfully eliminated from sober geological speculation."

Mr. Judd is especially well qualified for the task of describing from the geological standpoint the coming of evolution. He knew intimately both Charles Darwin, who convinced the world of organic evolution, and Charles Lyell, the great master of inorganic continuity who prepared the road for the *Origin of Species*. After the death of Lyell, it was to Judd that Darwin turned as a geological friend, with whom he could revive the memories of his own early work in that field and discuss recent developments. It is interesting to note the date at which Darwin formed his high opinion of Mr. Judd. In 1871 he wrote to Lyell as follows (*Life and Letters of C. Darwin*, III., p. 90): "In your last letter you spoke of Mr. Judd's paper on the volcanoes of the Hebrides. I have just finished it, and to ease my mind must express my extreme admiration. It is years since I have read a purely geological paper which has interested me so greatly. . . . I was also not a little pleased to see my volcanic book quoted, for I thought it was completely dead and forgotten. What fine work Mr. Judd will assuredly do!"

Mr. Judd speaks with enthusiasm of the characters of the two men who are the heroes of his story. "Every man of science," he writes, "is proud, and justly proud, of the grandeur of character, the unexampled generosity, the modesty and the simplicity which distinguished these pioneers in a great cause." He goes on to point out that, in the story of evolution as far as the great masters in that science are concerned, no event occurred to mar "the harmony of this band of fellow-workers, striving towards a great ideal."

Yet, by smaller men, Darwin's character was misunderstood and misjudged. For instance, his relation to his professor has been described as that of a thief who tries in vain to hide his pilferings. Mr. Judd makes some excellent remarks which bear on these accusations, though not directed to that point. He says, "It is not, as sometimes suggested, the striking out of new ideas which is of the greatest importance in the history of science, but rather the accumulation of observations and experiments, the reasonings based upon these and the writings in which facts and reasonings are presented to the world—by which a merely suggestive hypothesis becomes a vivifying theory—that really count in making history." He also quotes some characteristic words by Mr. Wallace, "I have long since come to see that no one deserves either praise or blame for the *ideas* which come to him, but only for the actions resulting therefrom. Ideas and beliefs are certainly not voluntary acts. . . . But the actions which result from our ideas may properly be so treated, because it is only by patient

thought and work that new ideas, if good and true, become adopted and utilised, while if untrue, or if not adequately presented to the world, they are rejected or forgotten." It is to be hoped that reasonable people realise this, and that the world in general does not imagine that when Darwin spoke of "my theory" he claimed to be the discoverer of evolution and that he may therefore be accused of trying to steal the glory of Lucretius!

Elsewhere (p. 9) Mr. Judd refers to the question which is here involved, viz., Mr. Darwin's position as regards natural selection and the theory of descent. He says that Darwin "attaches infinitely less importance to the establishment of the fact of the evolution of species than to a demonstration of a possible *mode of origin* of that evolution." This is not happily expressed, and does not harmonise with Mr. Judd's statement taken as a whole. What Darwin cared for primarily was the doctrine of descent, without which taxonomy, morphology, geographical distribution, and indeed the whole of our outlook on natural history, become barren and meaningless. He cared for natural selection as a weapon, or rather as *the* weapon by which the world, including himself, might be convinced of the descent theory. History justifies his attitude, for the world is now convinced of the fact of evolution, and the conversion was wrought by natural selection. Nowadays a new generation has arisen which does not realise its importance. It continues to believe in the doctrine of descent, but regards natural selection as a platitude.

After this digression, suggested by Mr. Judd's interesting hint on the difference in merit between *ideas* and their elaboration, we must return to and consider the general plan of the book. Chapter II. gives the early history of the idea of evolution and points out what is sometimes forgotten, that there have never been more than two theories as to the origin of species, namely the fashioning of species out of dead matter, or their descent with modification from pre-existing forms (p. 14). Mr. Judd here makes a striking point by quoting Milton's lines, "The earth obey'd, and straight, innumerable living creatures . . . opening her fertile womb, teem'd at a birth." And he asks which of these two sons of Christ's College, Milton or Darwin, had the grander view of creation?

Chapters III., IV., and V. give a vivid account of the "development of the idea of evolution in the inorganic world," the "triumph of catastrophism over evolution," and the "revolt of St. Roche and Lyell against catastrophism." At the beginning of the last century the early pioneers of evolution in the inorganic world—Generelli, Desmarest, and Hutton—having utterly failed in their efforts to convince the world, evolutionary ideas were almost universally discredited; so that the leading geologists were almost without exception firm adherents of catastrophism. The world is familiar with Lyell's rôle as the destroyer of this doctrine, but we doubt whether the non-geological reader is prepared for the important position assigned to St. Roche. Yet Mr. Judd makes good a case in his favour.

Chapters VI. and VII. are given to the influence of Lyell's works. Lyell's education at Oxford was purely catastrophist, Buckland teaching him that "all the superficial deposits

* *The Story of the Great Revolution in Science*, by John W. Judd, C.B., F.L.D., F.R.S., formerly Professor of Geology and Dean of the Royal College of Science, (Cambridge: The University Press.) 1910, 1s. net.
† *Life and Letters of C. Darwin*, ii., p. 190.

of the globe were the result of the Noachian deluge" (p. 46). Lyell found, in his own observations, an antidote to such instruction. For instance, in his work on certain shallow lakes in Forfarshire which were being drained and quarried, he discovered, under peat containing an ancient dug-out canoe, calcareous deposits passing into solid crystalline rock. He found evidence, too, for continuity in the action of the sea along the English coasts, and, speaking generally, it seems clear that he worked out his own salvation independently of earlier observers such as Hutton. From the last-named geologist he did indeed learn something, namely, the necessity of avoiding the *odium theologicum*, and the advantage of writing in a clear and attractive style. But in these things Hutton was a warning, not a model.

Lyell had great admiration for Gibbon, and according to Mr. Judd it is not improbable that he learned from him "that a frontal attack on a fortress is much less likely to succeed than one of sap and mine." We find an

having produced a revolution in natural science." Nothing can be stronger than Mr. Judd's views on this point, "Were I to assert that if *The Principles of Geology* had not been written, we should never have had *The Origin of Species* I think I should not be going too far; at all events, I can safely assert, from several conversations I had with Darwin, that he would have most unhesitatingly agreed in that opinion" (p. 73). In Mr. Judd's article on Darwin and geology (*Darwin and Modern Science*, 1909, p. 353) he published some interesting and original speculations as to the time at which Darwin began to be an evolutionist. He makes a point of the fact that the second volume of Lyell's principles, in which organic evolution is discussed, reached Darwin in November, 1832, at a time when his recent knowledge of the great fossil bones and his general experience of South American zoology were beckoning him towards evolution. Mr. Judd goes so far as to say that "we may confidently fix upon November, 1832, as the date at which Darwin commenced

ing the seven years that elapsed after the death of Lyell, I saw Darwin from time to time, for he loved to hear 'what was doing' in his favourite science. On board the "Beagle," before he had met the man whose life and work were to be so closely linked with his own, he was in the habit of specially treasuring up any "facts that would interest Mr. Lyell"; in middle life he declared that "when seeing a thing never seen by Lyell, one yet saw it partially through his eyes"; and never, I think, did we meet after the friend was gone, without the oft-repeated query, 'what would Lyell have said to that?'"

This picture of the lifelong influence of Lyell on Darwin might have fitly closed our remarks on Mr. Judd's study of the two great masters of evolution. But we must allow ourselves one more quotation from Mr. Judd's final page. He points out that all the world is now in agreement with Darwin's words:—"I believe that I have acted rightly in steadily following and devoting myself to science," and continues:—"For has not that devotion resulted in a complete reform of the natural history sciences! The doctrine of the 'immutability of species'—like that of 'catastrophism' in the inorganic world—has been eliminated from the biological sciences by Darwin, through his *steadily following* the clues found by him during his South American travels, and continuity is now as much the accepted creed of botanists and zoologists as it is of geologists." *Francis Darwin.*

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM CHARLES SLADDIN.

This pretty hybrid (see fig 25) was raised from a cross between *C. glaucophyllum* and *C. bellatulum*, and is the first hybrid of *glaucophyllum* to obtain an Award of Merit. The flowers are rounded, being superior in this respect to any of the *C. Chamberlainianum* crosses, although *C. glaucophyllum* is a close ally. The ground is white; both the petals and dorsal sepal are marked with claret colour, and a suffusion of rose extends between the veining. The spotting of the lip is a claret purple colour. It is one of Messrs. Sander & Sons' novelties.

CALANTHE VEITCHII.

Mr. B. GOODACRE has forwarded a photograph of a group of *Calanthe Veitchii* flowering in the Orchid houses at Moulton Paddocks Gardens, Newmarket. The number of flowers on the individual spikes range from 60 to 75. Mr. Goodacre states that the spike of 75 flowers is the best inflorescence of this Orchid grown at Moulton Paddocks.

CYPRIPEDIUM MISS ALICE WALLACE.

A FLOWER of this very beautiful *Cypridium* is sent by Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins), who states that the parentage is *C. Prospero majus* × *C. Sallieri* *Hycanum*. Therefore, the parental proportions in the new hybrid are *C. insigne* 2, *C. Spicerianum* 1, and *C. villosum* 1. As a flower it is in the same class as *C. Rossetti*, *C. Eve*, *C. aureum* *Surprise*, and *C. insigne* *Sanderæ*, the snow-white of the upper two-thirds of the dorsal sepal being even clearer than in *C. insigne* *Sanderæ*. The basal third of the dorsal sepal is emerald-green with a dozen or so small dark spots. The petals are nearest to *C. villosum* *aureum* and over an inch in width, pale yellowish-green veined with light green. The broad lip and staminate are chrome yellow, the lip having a faint greenish veining and a slight trace of sepia brown.

"THE ORCHID WORLD."

THE January number of this new publication has a most exhaustive and well-illustrated account of the *Cochliodas* by Mr. de Barri Crawshaw. A good portrait of Monsieur Firmin Lambeau is given, and some account of his fine collection of Orchids.

FIG. 25.—CYPRIPEDIUM "CHARLES SLADDIN."

(The first hybrid of *C. glaucophyllum* to obtain an Award of Merit.)

echo of the "sap and mine" method in 1863, when Darwin wrote to Lyell protesting against the half-hearted way in which the pedigree of the human race was treated in the *Antiquity of Man*; Lyell characteristically replied, "You ought to be satisfied, as I shall bring hundreds towards you who, if I had treated the matter more dogmatically, would have rebelled."

The interest of Chapter VII. lies in Mr. Judd's convincing argument in favour of the greatness of Lyell's influence on the progress of organic evolution. When Darwin started on the voyage of the "Beagle," which was to be his school in matters scientific, his Cambridge friend and teacher, Henslow, told him to read Vol. I. of *The Principles of Geology*, but not to be misled by it, since it was "altogether wild as far as theory goes." Darwin, however, at once discovered the value of Lyell's theories, and his mature judgment is given in *The Origin of Species*, where he spoke of "Lyell's grand work on the principles of geology, which the future historian will recognise as

that long series of observations and reasonings which eventually culminated in the preparation of *The Origin of Species*. In the present work (p. 103) Judd puts it less strongly, "I think there can be no doubt that from this time Darwin came to regard the question of species with an interest he had never felt before."

The writer of this notice is inclined to lay more weight on the latter part of the "Beagle" voyage in regard to the "new light" that was rising in Darwin's mind. In this he relies especially on Darwin's statement written in 1837 that it was especially (though not exclusively) the study of the Galapagos archipelago in 1835 that led him to evolution. It will be seen that both the above opinions are opposed to Huxley's view that it was not till the voyage was over that the materials and experience of Darwin's five years' work produced an essential evolutionary trend in his thoughts.

In an interesting passage at the end of his book (p. 157) Mr. Judd shows how enduring was the influence of Lyell on Darwin: "Dur-

APPLES IN DORSET.

HINTS TO SMALL GROWERS.

(Concluded from p. 31.)

THE poor price for cider Apples has necessitated the ordinary fallings being carefully collected and graded, and only badly bruised and very small ones were allowed to accumulate with those cider fruits in the heaps. Most of the cider varieties have been tested as to their cooking qualities, and not a few have been found to be usable if mixed with ordinary ones, especially if kept a while previously, when many of them mellow appreciably. To resume: all are gathered as soon as ever the fruit permits, thereby saving many bushels

of a hundredweight to those of a modest peck. There are various ways of making known that one has produce to dispose of beyond one's own neighbourhood, and, with fair luck, one is able to send these Apples at not excessive rates to London and near counties, where they realise better prices than those obtainable at home, seeing that locally the merits of your Dumelow's Seedling (Wellington) and Northern Greening, or even Blenheim Pippin, are but little understood, or confused with the crowd, for in the country oftentimes an Apple is but an Apple. Of course, there are exceptions, but these are usually from pure fancy or even misplaced prejudice. Several very inferior varieties, as modern ideas deem them, have been known to obtain

In a dear year, people will often be glad of faulty Apples, which, especially of early kinds, will do to cut up at once. For such they will pay a comparatively low price rather than give 3d. and 4d. per lb. for what, in an ordinary season, they can get for 1d. or 2d. 1 class under this heading fruits penetrated by maggots, misshapen and slightly bruised, but not decaying Apples. Small Apples, too, are sometimes put up with, and, like the former, well got rid of; indeed, the speedier the better. Never, under any consideration, should undersized fruits be allowed to go in the ordinary way; they spoil the sample, and give dissatisfaction out of all proportion to their insignificant number or relative weight. Another point is to make a speciality of large

FIG. 26.—OLEARIA FORSTII.
(See p. 52.)

which would otherwise be blown off by the gales and lose two-thirds of their value. Names, if not already known, are carefully ascertained, and the various sorts are systematically laid on straw in a warm shed or cool room, and labelled. A certain amount of grading is at once carried out, and consideration is specially taken of early, mid season, and late varieties, both as to dessert and cooking sorts. From time to time, of course, all lots are carefully examined and decaying fruits discarded. Determined not to depend on local prices a few seasons back, some two dozen different-sized hampers were purchased, the sizes varying from those with the capacity

curiously-inflated prices. Colour often seems the talisman. Thus old-fashioned Tom Putt always seems popular, and, as I think, rightly, seeing that it is an excellent, juicy cooker, whilst in flavour and attractive rich-red colouring it is sufficiently good for the dessert table. Little hard, golden Wylen Pippin, with its crisp, aromatic flavour, will fetch more money in its own district in Warwickshire than probably any other variety in the orchard. The carrier, who was also the dealer, always made a point of bespeaking all my orchard produce, invariably hinting that we should not quarrel as to price. Down here the variety would be little esteemed.

fruits for baking. Many trees produce a few abnormally large ones, whilst some varieties bear them as the rule and not as the exception. There is no more occasion to give these in with the order than there is to include undersized fruits; the great thing being to have each sample of uniform grade. These extra-big fellows, then, should be marketable at a really high price, for, where brought before customers, there is an astonishing keenness for them for baking separately, either in the ordinary way, or with a crust of paste enclosing them. Apples which lend themselves to this purpose are several of the Codlin tribe. Annie Elizabeth, Warner's

King, Beauty of Kent, Bramley's Seedling, Gloria Mundi, and Mère de Ménage, while Norfolk Beefing, Peasgood's Nonesuch, and Yorkshire Beauty, with many others, all of which produce, if not exclusively, yet mainly, Apples of considerable size.

Farmers in general (and many gardeners who ought to know better, even if the fruit is not grown for a profit) know very little about the names of their Apples, and may thus easily be defrauding themselves by selling choice fruit, such as Irish Peach, to instance an eating Apple, or several which are practically equal to Cox's Orange Pippin in profit-bringing properties, to wit, old-fashioned Margil, Cockle Pippin, and the modern Houblon, as ordinary Apples at poor local rates, while such splendid late keepers as Winter Quoining or Chelmsford Wonder may all go the same unprofitable way. In any case, it is exceedingly easy to be mistaken, or to be, so to speak, entertaining an angel unawares. Thus, recently I gathered a fair-sized crop of a distinctive-looking Apple, but which was also almost universally scabbed. Not having gathered from the tree before, I sent a sample to an expert to be

OLEARIAS IN IRELAND.

THE Olearias are evergreen shrubs, or small trees closely allied to the shrubby Asters, and are sometimes called Daisy bushes. The genus numbers about 100 species, 35 of which are endemic to New Zealand and the Chatham Islands, the remainder being confined to Australia, Tasmania, and Lord Howe's Island. Unfortunately, they are not generally hardy; even *Olearia Haastii* cannot be justly called hardy in districts further north than the Midland counties of England. Last winter a group of fine specimens, each about 7 feet high, was killed to the ground-level at Edinburgh, although some younger plants near to them escaped injury. The mild climate of Ireland suits many of the Olearias, and the visitor in May is usually delighted with *Olearia stellulata*, bushes of which are to be seen throughout the southern counties, 8 feet and more than this in diameter, and just one mass of white flowers. It is followed, in June, by *Olearia macrodonta*, which forms bushes 8 feet to 10 feet high, more in diameter, and loaded yearly with flowers. *Feta*, the residence of Lord Barrymore, can probably claim the largest specimen in the country. It is 10 feet high by 12 feet through. The freedom

good size: the sweet-smelling wood is used for cabinet work. The leaves are handsome and musk-scented, about 4 to 6 inches long, light green above and silvery beneath. At Glasnevin, it lives against a wall, but during a severe winter is killed to the ground-level, shooting up again in the spring. At Howth, where it flowers annually, it is planted in a dry corner formed by two walls. The flowers are small, yellowish, and produced in large hanging clusters.

O. AVICENNIFOLIA was imported last year from New Zealand, and flowered freely in September. The flowers, which are borne in large erect clusters, are small and white, but not showy. The leaves are like those of the stove *Avicennia* in shape, green above, but with a beautiful fawn-coloured under-surface, and about 3 inches long.

O. CHATHAMICA is a very distinct species, said to grow 3 to 6 feet high. At Glasnevin, against a wall, it passed through last winter with slight damage. The leaves are 3 inches long, broader than *O. angustifolia*, glossy-green above, and the under-surfaces of leaf, stalk, and branches are covered with a dense, white tomentum. This species flowered at Glasnevin in June. The flowers are an inch or more across, almost bluish, with a purplish disc. For the southern counties *O. chathamica* is very promising; it is to be hoped it will soon become more plentiful.

O. FORSTERI (see fig. 26), a handsome evergreen shrub fairly common in Dublin gardens, is a quick grower, and forms an erect bush about 6 to 8 feet high. The leaf has a beautifully waved margin, and is whitish on the under-surface. The flowers, sparingly produced in late autumn, are inconspicuous but fragrant.

O. FURFURACEA (syn. *ferruginea*) makes a bushy plant, with clusters of small, white flowers by no means effective. Last winter this shrub was severely cut by frost, whereas *O. Forsteri* escaped without injury.

O. HAASTII (see fig. 27) is the commonest of all, yet one of the most useful species, its tough, Box-like leaves making it a most serviceable evergreen for towns, and a really first-rate seaside shrub, for it will stand in exposed places within reach of the salt water spray. It will endure a fair amount of shade, and makes a well-shaped specimen without any trimming. Though a moderate grower, yet in time it will cover a large space. At Castlewellan, one specimen was about 16 feet through. Though not so beautiful as some of the species, yet its profusion of blossom in August is a welcome sight.

O. ILICIFOLIA.—This species has been confused with *O. macrodonta*, but is quite distinct. The leaf of the true *O. ilicifolia* is 2 to 3 inches long, lance shaped, about half the width of *O. macrodonta*, not rounded at the base, and the veins run at right-angles to the mid-rib. Both have the same musky fragrance, and the leaves are whitish underneath.

O. INSIGNIS (see fig. 28) stands out as the most remarkable plant in the genus. The photograph shows a specimen, which is probably the finest in Great Britain, growing in Mr. Gumbleton's garden at Belgrove, Queenstown, where it flowers freely every year. The plant measures 2 feet 4 inches in height by 2 feet 6 inches in breadth. At Glasnevin, it usually flowers against a wall, but needs protection in winter. It is a native of the Middle Island, New Zealand, where it grows at a great elevation in the crevices of dry, shaly rocks. The leaves, exceedingly thick and leathery, are about 6 inches by 4 inches. When young, the whole leaf is covered with a thick, white down; but this disappears from the upper surface, which then appears glossy-green. The flowers are solitary, borne on 10-inch peduncles, as thick as a goose quill, covered with down, and each flower measures about 2 to 3 inches in diameter, and has white ray florets, with a yellow disc.

O. LACUNOSA is very curious and distinct. Its long, narrow leaves stand out at right-angles to

FIG. 27.—OLEARIA HAASTII.

named. What was my surprise to find it to be "Wellington," and quite unmistakable on comparing it with another lot of Wellingtons I happened to possess, though the latter was a far more normal and satisfactory crop.

My last suggestion is against very late keeping varieties. It may not be generally known that Apples lose enormously in weight as time goes on. Unless they are extremely carefully housed, moreover (and even despite of it), there is usually great loss, and very frequent looking over is necessary, while I doubt if after March people care much about Apples either for cooking or dessert. The winter is over, people are tired of the staple, dead-season stand-by, Oranges are plentiful and sweet, Bananas are within everyone's reach and almost a drug in the market, and forced Rhubarb is selling at a very reasonable rate, while one's thoughts begin to turn to Gooseberries with their foretaste of spring and summer. In conclusion, I may ask why people do not utilise the Orange in tarts and puddings? It is excellent for the purpose and very cheap. *T. A. Carnegie Cheals.*

and continuity of flowering make these Olearias of the greatest value for Irish gardens.

These shrubs seem to prefer a fairly light, dry and well-drained soil. In the colder localities, some succeed as wall shrubs. As a rule, good seed is only sparingly produced in this country, but nearly all the species root very freely from cuttings in pots of sandy soil in cold frames; those having very downy stems take longer, and are more difficult to root. Twenty-seven species of Olearias are in cultivation at Glasnevin, 20 of which are native of New Zealand. Unless otherwise noted, the following come from New Zealand. For some of the rarer species the garden is indebted to the generosity of Captain Dorrien-Smith; others have been purchased and imported through Mr. H. Travers, of Wellington.

O. ANGUSTIFOLIA has not yet been tried in the open. The stalkless leaves are 3 to 5 inches long, narrow, and pointed, stiff in texture and spiny on the margin.

O. ARGOPHYLLA is a native of Australia, where it is known as the Musk Wood, and grows to a

the stem, reminding one of the habit of *Pseudopanax crassifolium*. The leaves are 6 to 7 inches long, and only three-quarters of an inch wide; they are green, with a yellow mid-rib, and reticulated above, downy underneath, with strong, lateral veins at right-angles to the mid-rib. Its hardiness has not been tested here.

O. LYALLII is a very rare and striking plant, specimens of which have been presented by Captain Dorrien-Smith to Glasnevin. It is said to have large, dark-brown flowers, and to grow 3 feet high. The leaves are handsome, from 4 to 6 inches long, ovate in shape, clothed when young with dense, white, woolly hairs, becoming glabrous when old. A variety of *O. Lyallii* collected by Captain Dorrien-Smith in Stewart Island is making free growth. It differs from the type in having smaller leaves, which are not covered so densely by whitish hairs.

O. MACRODONTA (see fig. 29) is second to *O. Haastii* in hardiness, but second to none in beauty. The leaves are Holly-like, and the plant bears freely large, flat corymbs of white flowers, with deeper centres. In old specimens, the thin outer bark peels off and hangs from the branches like tattered rags. The photograph (fig. 29) shows *O. macrodonta*, about 6 feet high, at Glasnevin, where it has been

O. NUMMULARIFOLIA is a rigid, erect, little bush, with white, starry flowers which appear about July. The leaves are only $\frac{1}{4}$ inch long, very thick and leathery, crowded on the shoots, green above, and whitish below, with the margins recurved. The young growths are sticky and golden. It is a very distinct evergreen, and, owing to its very slow growth, it makes a good rockery shrub. Frost has not injured it at Glasnevin, although last winter 23° were registered here. It is well worth trying in other places.

O. OLEIFOLIA is something like a large *O. Haastii* in flower and habit, and flowers about the same time, or a little later. The leaves are narrow, about 2 or 3 inches long. It passed through last winter at Glasnevin without any protection.

O. PANNOSA is an Australian species, with thick, ovate leaves, 2 inches long, covered on the underside with a thick, dense tomentum. It is hardy in Wicklow and the south, but is not a showy shrub.

O. RAMULOSA is also a native of Australia, without much claim to hardiness, for it is killed outright in Co. Wicklow. At Glasnevin, it is grown as a pot plant, and makes a very pretty subject. The leaves are very small, only $\frac{1}{8}$ inch

ter reduced it to less than half that height. With Mr. Gumbleton, it reached 25 feet before being cut down by a severe winter. It is easily recognised, for the young branches are square and are covered by a silvery tomentum. The leaves are opposite, 2 to 2½ inches long, and broadly ovate, bright green above, and beautifully silvery underneath. Axillary panicles of flowers are borne, but they are not showy.

O. VIRGATA has not been tried in the open at Glasnevin, but it is not a striking plant. It has linear leaves, in opposite fascicles, with small and dull flowers.

Other species in cultivation at Glasnevin, but which have not flowered nor have been tried in the open, are:—*O. Buchananii*, *O. Cunninghamii*, and *O. lyrata*. *O. lyrata* is tender, but lives and flowers in the open with Dr. Heard in Co. Kerry. *O. odorata* is grown by Sir John Ross, of Bladensburg, at Rostrevor, in Co. Down. It is related to *O. virgata*, but differs in having cylindrical branchlets, with larger and broader leaves. *C. F. Ball, Glasnevin Botanic Gardens, Dublin.*

CULTURAL MEMORANDA.

RHUBARB FORCING BY AMATEURS.

ONE so often sees unsuccessful, or partially successful, attempts to produce early Rhubarb in small gardens that perhaps an account of a method that has proved satisfactory for many years may not be out of place.

Strong clumps are selected and lifted, and most of the soil is carefully removed from them with a pointed stick. They are then left on the surface of the ground for a week or 10 days to dry, and, if the weather is favourable, to be well frozen through. The freezing is important, as the frost has the effect of making all the crowns start into growth simultaneously as soon as they are placed in heat, just as with "retarded crowns of Lily of the Valley." The failures from several crowns refusing to start into growth at once may be traced to neglect of this precaution.

After exposure, the roots are placed closely together, all interstices being firmly filled with soil or ashes. Being dependent on manure for obtaining heat, I make an oblong bed of the roots and enclose it in a framework of wooden battens. Wire netting is stretched round the sides, and sheets of corrugated iron placed over the top.

Straw from the stables, in a state of fermentation, is then placed round the outside, enclosing the whole in a wall of manure, firmly trodden, and from 15 inches to 18 inches thick. This manure keeps its heat for a long time. Rhubarb roots lifted in Christmas week will give a supply that will last until that from the open garden is available. Only just enough manure to keep the heat in is placed on the top, and this and the iron sheets can be easily removed to enable one to pull the Rhubarb.

As to watering, the roots should be kept rather on the dry side. A mild day should be chosen for watering (with tepid water), and the bed should be left open for an hour or two after the operation to allow superfluous moisture to evaporate. Rhubarb soon shows a lack of water by the absence of that crisp firmness essential to good quality.

The proper treatment of the roots after forcing is important. My theory is that a period of rest is beneficial, and I leave the roots *in situ* where they were forced (the manure being removed), and plant them out in summer or early autumn. They are allowed one year's growth in the open ground before they are forced again. If the roots have not been over-forced they soon recover, but excessive forcing is a mistake.

The practice of forcing the roots without lifting them results in failure, the benefits of the retarding being missed, and often, through the lack of a proper system of rotation, the same roots are forced for two years in succession. *Harold Evans, Llanishen, Cardiff.*

FIG. 28.—OLEARIA INSIGNIS IN MR. GUMBLETON'S GARDEN, BELGROVE, CO. CORK.

(See p. 52)

rather overcrowded in a shrubbery. A curious dwarf shrub, known as *O. macrodonta minor*, has been distributed from Mr. Hart's garden at Howth. Its origin is unknown, but it has been there many years on the rockery, and is still only 2 feet high, forming a dense, compact, little bush, just like a miniature *O. macrodonta*, but up to the present it has not flowered.

O. MOSCHATA makes a small, whitish leaved shrub, with small flowers. Near the sea at Clontarf, it forms a compact bush 2 to 3 feet high, with a strong, musky fragrance.

O. MYRSINOIDES (see fig. 30) is an Australian species, with small, spiny leaves, and a rather straggling habit. At Glasnevin, it is grown as a wall shrub, but in the south of Ireland it makes an ornamental bush, with long sprays of small, white flowers. By some nurserymen, this plant is still known as *O. ilicifolia*.

O. NITIDA has ovate leaves, silvery underneath. At Glasnevin, it is not a great success, but further south it is one of the most beautiful summer-flowering shrubs. It is quick-growing and free-blooming when happy. The flowers are produced in clusters, white, with yellow disc.

in length, and the white flowers are produced on spray like branches.

O. SOLANDRI is an erect, much-branched shrub, hardy with Mr. Beamish near Queenstown, and said to grow from 5 to 15 feet high in New Zealand. At Glasnevin, it has not been tested out-of-doors, but is a twiggy and rather pretty little bush, with dark stems, and light green opposite leaves, about $\frac{1}{2}$ inch long, lanceolate obovate in shape.

O. STELLULATA is a native of Australia. It is the *O. Gunniana* of Hooker, and of gardens. The true *O. Gunniana* is said to have smaller flowers, is later in flowering and less hardy. *O. stellulata* is often called the Daisy Bush, and sometimes the flowers are produced in such profusion that the foliage is hidden. Large bushes are fairly common in the south. In the colder counties, it makes a beautiful wall shrub, or a good pot plant for a cold house. *O. stellulata macrocephala* has larger flowers and leaves, but does not flower quite so freely as the type.

O. TRAVERSII, in New Zealand, grows into a small tree about 30 feet high. At Glasnevin, it makes an ornamental evergreen about 10 feet high, but is rather tender. The last severe win-

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

CYPRIPEDIUM.—The late autumn and winter-flowering *Cypripediums* are not only valuable from a decorative point of view, but they may be cultivated with comparatively little trouble. Another advantage is that the plants occupy a small space, and yet produce a wealth of bloom. They include *C. insigne*, together with its numerous varieties; *C. Charlesworthii*, *C. Fairreanum*, *C. Spicerianum*, *C. villosum*, *C. Boxallii*, and the numerous hybrids raised from these species. The plants do best in what may be termed a cool, intermediate temperature, although they can be grown successfully in an ordinary greenhouse, where a temperature of not less than 45° is maintained in winter. They will need great care in watering during winter, and shade must be afforded them during bright sunshine at other seasons.

WARM-HOUSE CYPRIPEDIUMS.—To this class belong the spring and early-summer flowering plants. Such species as *C. Stonei*, *C. Rothschildianum*, *C. Curtisii*, and *C. Sanderianum* should be placed in the warmest division of the house, whilst *C. Lawrenceanum*, *C. barbatum*, *C. superbiens*, and *C. callosum* with their hybrids grow best in an intermediate temperature. The flower-buds of many of these plants will appear shortly. These *Cypripediums* are, as a class, less susceptible to injury from excessive moisture than most other Orchids, and this refers especially to those with tessellated foliage, even at the stage when the flower-spikes are partially enclosed in the centre leaves. But it will be well in affording water at this season to take care that the moisture does not lodge in the crown of the plants, for I have known cases of specimens rotting from this cause. Any water that lodges in this way should be removed as soon as possible.

REPOTTING OPERATIONS.—Any specimens that have finished flowering should be examined to see if repotting or fresh rooting material is necessary. If large specimens are required, select plants that are root-bound, and afford them a liberal shift, as the majority of these *Cypripediums* form roots freely. The quantity of materials used for drainage need not be excessive; a layer of about an inch in depth will suffice, provided the crocks are carefully arranged and covered with pieces of turf to prevent the finer particles of soil getting into them. In potting, keep the base of the plant a little below the rim of the pot, working the materials firmly amongst the roots. A suitable compost consists of good fibrous loam one-third, turfy peat or *Osmunda* fibre one-third, and the remainder of leaf-soil and *Sphagnum*-moss in equal parts, adding a good sprinkling of coarse silver sand and small pieces of crock. The materials should be well mixed together, and employed in a fairly moist condition, so that no water will be necessary for a few days after potting, when the plants may receive a good soaking. After this initial watering great care must be exercised in applying moisture to the roots, but when the new roots ramify in the soil copious supplies of water may be afforded them.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

THE VINERIES.—Any bunches of late Grapes that may still be hanging on the vines should be cut and placed in the Grape or store room, with their stalks immersed in water. Before doing this, examine the berries carefully, and remove any that show signs of decay. I find the bottle, invented by Mr. Bullock, of Coppell Hall Gardens, valuable for the purpose. Complete the cleansing and pruning of the vines, and, when the roof has been cleaned down, tie the rods in their permanent positions. The borders may then be carefully tidied and very lightly forked over, but care must be taken not to damage the small, fibrous roots near the surface. Apply a good sprinkling of wood ashes and bonemeal, and

over these materials a layer of chopped loam or turves that have been stacked for some time.

EARLY VINERY.—The rods which have been bent down to encourage them to break evenly, and also to facilitate the use of the syringe, should be released carefully before the growths get too large, and tied in their proper positions. Continue to syringe the rods and growths with tepid water whenever the weather is bright. Ventilating must be done with discretion, for whilst a circulation of fresh air is required to prevent a stagnant atmosphere, and also to promote a sturdy growth, cold draughts are harmful.

LATE FRUIT HOUSES.—The trees and vines should be kept as dormant as possible. Admit an abundance of fresh air, and, in the event of a frosty night, circulate a little warmth in the hot-water pipes.

SUCCESSIONAL PEACHES.—Peach trees in mid-season and late houses and those in unheated "cases" should now be got ready for starting when the time arrives. The first thing to do is to cleanse the houses and trees according to directions already given. Cut away the ties and remove the trees from the trellis, then prune the trees neatly and well with the aid of a sharp knife, cutting away all superfluous growths and retaining as many of the shoots formed last season as are required. Avoid overcrowding, and endeavour to clothe the tree as evenly as possible with the new shoots, leaving plenty toward the base. Train the growths as neatly as possible, first laying in the older wood, so that the branches radiate evenly, and filling in the smaller wood accordingly. Where the wires are some considerable distance apart, it is sometimes a difficult matter to keep the shoots perfectly straight; in that case it is necessary to take a neatly-twisted strand of raffia at right angles, and then secure the shoots with another tie. The borders should be given a good soaking with clear water on showing signs of dryness; this does much to prevent the buds dropping when started. Give a top-dressing of chopped loam, which should be free from any live growth, and to which has been added a good sprinkling of wood ashes and lime rubble. Apply a mulching of manure over the loam, either of horse droppings or well-decayed farmyard manure.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

VIOLETS IN FRAMES.—Ventilate the frames containing Violets on every favourable occasion, but do not expose the plants to keen winds. Even in dull, damp weather a little air is desirable. If the clumps are planted somewhat closely together, or if a liberal amount of foliage has been made, take care to remove any which show the least signs of damping. On a favourable day the lights may be removed and the plants examined, taking the opportunity thus afforded to stir the surface of the soil. For covering Violet frames in frosty weather, waterproof sheets are better than mats. When severe frosts occur the sides of the frames, if of wood, should be banked up with leaves.

SOILS.—At this season of the year it is good practice to secure a plentiful supply of the various soil ingredients in readiness for potting purposes. Loam becomes too dry if kept under cover for a considerable length of time, therefore it is a good plan to have the major part exposed to the air out-of-doors, and to bring instalments indoors some little time before they are needed for use. Take means to ascertain whether there is wireworm or caterpillar in the loam, in which case it may be necessary to sterilise the material. Two kinds of loam will be found useful, first a soft, silky loam, somewhat of a sandy nature, and, secondly, a loam of heavier consistency; in both cases the loam should be tough and fibrous in character. The silky loam will suit plants having a delicate root-system, such as *Dipladynias*, whilst the stronger loam will suit plants which root more freely, such as the *Allamanda*. Leaf-mould should be prepared from the fallen leaves of Oak and Beech trees, and kept as free as possible from the dead leaves that have fallen from evergreens. The best leaf-mould for general purposes will be that which was formed from leaves in 1909. Silver sand should always be stored in a dry place. The peat should be of two distinct qualities, one

possessing a tough fibrous character yet somewhat soft to handle, and the other of a harder nature. The tough, fibrous peat will suit most stove plants, whilst the harder material is better for such plants as *Rhododendrons* (including *Azaleas*), *Heaths* and *Epacrises*. The softer peat is usually cut in thicker layers than the harder sort. There should not be much waste in the softer peat, but the harder peat may contain some waste on the under side, where the soil contains no fibre, and is unsuitable for pot plants. Lime rubble and old mortar rubbish (not cement) are useful for mixing in various composts. Charcoal is an excellent absorbent and of great value for certain hard-wooded plants. A small stock of *Sphagnum*-moss will be necessary for *Allocaσίας*, *Anthuriums*, and similar plants.

FLOWER-POTS. Examine the store of flower-pots, see that all in stock are cleansed thoroughly and that they are drained with clean crocks. Pots should be stored in a dry place. Additions have to be made in most seasons to the stock of flower-pots, and the order for these should be despatched as soon as convenient.

THE FRENCH GARDEN.

By PAUL AQUATIUS.

HOTBEDS.—The hotbeds should be completed by the end of January. Those that are formed last are utilised for growing Radishes and Lettuces. Their full value will be found later, after the Lettuces have been gathered early in March, as they are then available for forcing early Turnips, which prove a very remunerative crop. Newly-formed hotbeds are not to be recommended for forcing Turnips early in the year, as the plants make excessive foliage at the expense of the roots. The Radishes and Lettuces sown on the first hotbeds have appeared above the ground, and it will be necessary to place linings of fresh manure to the frames in order to keep up the required temperature. Short and well-broken manure is used for lining the outside of the frames; it is placed in position with a fork and afterwards made firm and even by means of a shovel. In the paths between the frames, long and dry manure only is employed. If no long manure is available, good results may be obtained by mixing some straw with short manure. In any case, it is essential to use the material in a dry condition, as the moisture that percolates from the frames would cause the materials, through constant treading, to form a soft and disagreeable path for the workman. The manure is carried in baskets and placed on the top of the lights that have been previously covered with mats to protect the glass, it is then arranged by the hand until it is level in the path with the frames.

FRAMES WITHOUT HOTBEDS.—All these frames have been planted with Lettuces. A thin layer of straw or old hay is placed between the rows of frames to facilitate walking. This may appear a small detail, but it is very necessary, as it means a saving of labour. The Easter supply of salad will, this year, be entirely dependent on the Lettuces grown in the cold frames, and it will be necessary to afford the plants every care, as Easter is a somewhat early date for this crop. A portion of the ground intended for unheated cloches should be marked out in beds, each 4 feet 6 inches wide, allowing a path of 1 foot between each bed. The cloches are sown with National Radish, which is a larger variety than the round variety, French Breakfast. Cloches are placed in three rows on each bed, and as soon as the soil is in a proper condition, three plants of Passion Lettuce will be set under each bell-glass.

NURSERY BEDS.—Young Lettuces still in their winter quarters must be given ample ventilation during both day and night, in order to prevent a spindly and soft growth. Cauliflowers planted in frames are growing actively, and will need plenty of fresh air. If this batch of Cauliflower has proved unsuccessful, a few Cauliflower seeds may be inserted on the hotbed instead of the Radishes. It will be necessary to prick out the plants late in February, and suitable room should be arranged for them. If these late-sown plants receive proper attention, they will be sufficiently strong for planting in their final quarters late in March.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

ORCHARD FRUIT TREES.—These may be planted during open weather. Place a stake to each tree and apply a mulch immediately afterwards, not necessarily of manure, but of litter, or any suitable material that may be at hand; the object being to prevent frost from penetrating too deeply into the soil. In very exposed situations it may be desirable to cover the stems of recently-planted standard trees with haybands; the trees will not suffer so much from extremes of heat and cold during the season, and the coverings, if kept in a moist condition during the earlier months of the year, will very materially aid the trees when starting into growth, by preventing the too rapid evaporation of moisture from the tissues of the stem.

RASPBERRIES.—The canes will require but little pruning, or thinning, if they were properly cared for during the autumn. New plantations may be made, growing them, as fancy, or circumstances may dictate, either in groups fastened to stakes, or in rows trained to wires. The ground should be but lightly forked over—or, better still, if circumstances allow—hand-cleaned, afterwards giving the surface a good dressing of half-decayed manure. As a rule, Raspberries will continue in a good bearing condition for many years, but it is advisable to keep a supply of healthy young plantations, by planting a number of canes each year and destroying a corresponding number of old plants. Hornet, Perfection, Baumforth's Seedling, Fastolf, Northumberland Fillbasket, and Superlative are excellent red varieties for summer use. Of yellow-fruited kinds, Yellow Superlative and Yellow Antwerp are two of the best. Of autumn-bearing kinds, Queen Alexandra, November Abundance, and October Red may be recommended for districts favourable to their culture.

PEACH TREES.—In the cultivation of outdoor Peach trees in this country the essential point to always keep in view is that of getting the shoots to mature perfectly each season. There are many circumstances that may hinder the maturation of the wood. For example, young trees should never be planted in highly-manured or excessively-rich soil, which can have only the result of causing unduly strong growths. The effects of such planting may sometimes be seen in immature shoots with leaves affected with the blister fungus, whilst gumming and canker may be present in the shoots of the previous year. When planting young Peach trees, the first thing is to provide perfect drainage, unless this exists naturally, and the warmest aspect the garden affords, taking care that the soil, though good, is not over manured. Then in the matter of pruning it is desirable to prevent overcrowding of the shoots. Much of the thinning of young shoots should be done in autumn, when those which have borne fruits may be cut away. Assuming that this was done last autumn, the amount of pruning necessary at the present season is very little; but it should be so done that the growths which are retained may be trained at distances of 4 inches apart. In shortening the growths, cut them back to triple buds, thereby making sure that a growth bud will be included amongst them. The shoots should be so shortened that any ill-ripened portion is removed by the cutting, it being far better to have shoots only 8, or even 6, inches long than to retain more buds on immature wood. By way of explanation to the younger gardeners, it may be stated here that the difference between wood and blossom buds may be seen quite easily, the blossom buds being round and plump, whilst the growth buds are thin and pointed. Where triple buds occur, the wood bud is usually the centre bud. It is interesting to note that some growths develop fruit or blossom buds all the way to the end or terminal bud, which is generally a growth bud; in such cases, the shoots should not be cut at all. Other shoots, on the contrary, have wood buds only, and are useless so far as fruiting next year is concerned; these may be cut back to two or three buds from the base. Some varieties of Peaches are inclined to make growths more vigorous than is desirable, and unless some check is applied to them, they develop unfruitful wood; therefore, the strongest growths should be pinched back to three or four leaves. The young buds will soon start into growth and produce lateral shoots, which will often make good fruiting wood for the following season. In the

training of Peach trees, sufficient careful pruning should be done every year to allow the cultivator to select for training a considerable number of young shoots, and, occasionally, old or useless branches may be removed from the tree. Excessively strong wood should be cut clean away, for its removal will prove of service to the general condition of the tree. After the pruning, each tree should be cleansed carefully. Apply a dressing of some approved insecticide to the stem and main branches, well working in the mixture with a fairly stiff brush. A softer brush must be used, and with extreme care, on the young wood, or the buds may suffer irreparable damage. I do not favour making the mixture of the consistency of paint, but prefer to use a thin, clear dressing.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, K.T., Tynninghame, East Lothian.

THE BOG.—An artificial bog, however small, is a pleasing adjunct to the rockery. A bog facilitates the cultivation of a great variety of plants which, in many gardens, fail to grow elsewhere. In it may be planted such favourites as *Orchis foliosa*, moisture-loving Primulas, such as *P. pulverulenta*, *P. rosea*, *P. japonica*, *P. capitata*, *P. denticulata*, and *P. cashmeriana*; *Lilium pardalinum*, *Astilbe Davidii*, *A. grandis*, *A. rubella*, Japanese Hises (*Iris Kämpferi*), the Flowering Rush (*Butomus*), Water Plantain, Royal Fern (*Osmunda regalis*), Sweet Gale (*Myrica Gale*), Bogbean (*Menyanthes trifoliata*), *Saxifraga Andrewsii*, *S. hypnoides*, and *Myosotis*. After removing the surface rubbish of all kinds, a compost of decayed manure, leaf-soil and loam in equal proportions should be distributed evenly. Primula rosea and the Astilbes are examples of plants that push their crowns so far above the surface as to leave many roots exposed. Hence, supplies of fresh surfacing material is to these of paramount importance.

THE WILD GARDEN.—The wild garden occupies a similar position to the Wilderness of the early part of the 18th century. Here, too, something must be done before the advent of spring. Strong-growing plants, such as *Polygonum sachalinense*, *Bocconia cordata*, *B. microphylla*, *Helianthus "Miss Mollish," H. laciniata*, *Pyrethrum uliginosum* and *Aconitum autumnale*, which, once established, soon extend beyond reasonable bounds, must be checked. None is difficult to keep in order, provided there is an annual eradication of the trespassing growths. Though very handsome, the Cow Parsnip propagates itself so liberally from seeds that it ought hardly to be admitted. A simple way to keep it in check is to apply sulphuric acid to the crowns of the plants. Myrrhis odorata and some of the Thistle family also extend unduly, but at least the Globe Thistle and *Onopordon Acanthium* should be allowed a place. Superfluous seedlings of the *Onopordon* should be dug up, but it must be remembered that young plants are essential for flowering the succeeding year. Plants that may be introduced, if absent, are *Spiraea gigantea*, *S. Ulmaria fl. pl.*, *S. venusta*, Lily of the Valley, Solomon's Seal, *Rumex Patientia*, *Rosa alpina*, *R. rubiginosa*, *R. rugosa*, *Iris foetidissima* (for its seed pods), *I. sibirica*, *Scilla nutans* and its white variety, *Verbascum Thapsus*, Foxgloves (which sometimes need thinning), *Phytolacca decandra*, *Anchusa sempervirens*, *Lythrum Salicaria*, *Campanula latifolia* (this plant is apt to overrun its bounds), *Geranium sanguineum*, *G. pratense* and *Epilobium angustifolium* (the white-flowered form is much less addicted to spreading than the type). Primroses should be mixed with Cowslips, when old-fashioned Oxlips as well as seedlings of the species will be produced. *Antholyza paniculata*, Snowdrops and *Eranthis hyemalis* should not be overlooked, whilst *Scilla italica* does well in a shady position.

SEED-GROWING.—Seeds of East Lothian Stocks should be sown without delay. The number of varieties has been increased materially in recent years, the rose and mauve colours being important acquisitions. The mauve colour is not always quite true, and it would be possible to select two or three charming shades, but even when these shades are mixed it is a lovely thing. Like Cruciferous plants in general, Stocks are easy to raise, the only cause for anxiety being the liability of the tiny seed-

lings to damp off. This may usually be prevented by seeing that the atmosphere is rather cool and dry and by exercising care in the application of water. If damping occurs, the surface of the soil must be sprinkled with dry charcoal dust, or, failing that, with dry, fine sand. It is also time to sow Pentstemons. These grow at first very slowly, and after being pricked off ought to be kept in a heated structure till well established. Of Antirrhinums, I do not care for the Tom Thumb section, but the best strains of Intermediate and tall-growing Snapdragons are invaluable. Of the Intermediate type, Yellow Queen, Sutton's Pink, Carmine Pink and Oliver's Crimson satisfy our wants, and of the taller-growing sorts, Moonlight Pink, Carmine Pink, Golden Chamois, Rosy Morn, Cloth of Gold, White-throated, crimson and Gold and White are good varieties. At the same time, it is not wise to plant untested varieties in the flower-garden, as some of the colours may not be desirable. Other plants to be raised from seeds at the present time include *Salpiglossis*, *Kochia triphylla*, *Canna*, *Commelina cœlestis*, Pansy, and *Lobelia* (of which Emperor William produces perhaps the most attractive shade of blue), *Salvia splendens "Pride of Zurich"* and a stock of *S. patens* may be obtained from seed, but many inferior forms result, and propagation of a selected variety by cuttings is to be preferred.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

ONIONS.—If extra large bulbs of Onions are required, suitable land should now be prepared for planting the seedlings. Select an open situation and ground that has been deeply cultivated and is in a good condition generally. Trench the land as soon as possible, and allow it to remain in a rough condition until March, when a good dressing of soot may be forked into it. About the middle of April, or later if the weather is unfavourable, the plants may be put out. The seeds should be sown now in pans or boxes, and germinated in a temperature of 50°. The soil for the seed pan should be of a rich, sandy nature, and made firm while in a moderately dry condition. Sow the seeds thinly, and cover them lightly with fine soil. When the young plants appear they should be placed close to the glass in order that they may grow sturdily. When large enough, they should be pricked into boxes of fine, rich soil at a distance of 3 inches apart each way. Later on, a little air should be admitted in order to prepare the plants for removal to a cold pit, where they should be gradually hardened off in preparation for planting out of doors in April.

RHUBARB.—The present is a good time to prepare ground for a fresh plantation of Rhubarb. Fresh beds should be planted each season, in order to furnish a supply of healthy plants for forcing and other purposes. Rhubarb delights in a deep, rich soil and an abundance of farmyard manure, which should be well mixed with the soil as the work of trenching proceeds. In the case of permanent beds, a distance of 5 feet should be allowed between the rows and 4 feet from plant to plant. March is the best month for planting Rhubarb, provided the ground has been prepared beforehand. Daw's Champion is the favourite variety with us; the stalks are coloured red right through, and the flesh is of a superior flavour.

FORCING ASPARAGUS.—Roots of Asparagus should be introduced to the forcing pit fortnightly in quantities suitable to the demand. If forcing has not already commenced, the best plan is to place the roots on beds of leaves trodden tightly together to the depth of 4 feet. Leaves are plentiful in most places, and they make the best beds for the purpose. At Windsor we cover the bed with well-decayed manure, over which is placed a thin layer of finely-sifted soil, so that the roots may not be placed in direct contact with the dung, but into which they soon find their way when growth commences. It matters little what age the roots may be, so long as they are strong and healthy. Our practice is to lift the oldest beds in rotation each season for forcing, planting a similar quantity in April to take their place. If allowed a bottom heat of 70° the plants will produce shoots ready for gathering in a little over a fortnight. When the young shoots begin to grow the whole bed should be covered with 4 inches of finely-sifted leaf-mould.

APPOINTMENTS FOR FEBRUARY.

- THURSDAY, FEBRUARY 2—
Linnæan Soc. meet.
- SATURDAY, FEBRUARY 4—
Soc. Française d'Hort. de Londres meet.
- MONDAY, FEBRUARY 6—
Dorchester Gard. Soc. meet. (Lecture on "Annuals.")
- TUESDAY, FEBRUARY 7—
Scottish Hort. Assoc. meet.
- THURSDAY, FEBRUARY 9—
Soc. Nationale d'Hort. de France (Paris) Exh.
- FRIDAY, FEBRUARY 10—
Roy. Gard. Orphan Fund Ann. Meet. and election of Orphans at Simpson's Restaurant, Strand.
- MONDAY, FEBRUARY 13—
United Hort. Benefit and Prov. Soc. Com. meet.
- TUESDAY, FEBRUARY 14—
Roy. Hort. Soc. Coms. meet at 12 noon. Ann. Meet. of Fellows at 3 p.m. Hort. Club Ann. Meet.
- WEDNESDAY, FEBRUARY 15—
Roy. Meteorological Soc. meet.
- THURSDAY, FEBRUARY 16—
Linnæan Soc. meet.
- MONDAY, FEBRUARY 20—
Nat. Chrys. Soc. Executive Com. meet.
- WEDNESDAY, FEBRUARY 22—
Irish Gard. Assoc. and Benev. Soc. meet.
- TUESDAY, FEBRUARY 28—
Roy. Hort. Soc. Coms. meet. (Fifth Masters' Memorial Lecture at 3 p.m. by Mr. G. F. Scott-Elliott, M.A., on "Recent Work in Seed Selection.")

AVERAGE MEAN TEMPERATURE for the edshing week deduced from observations during the last Fifty Years at Greenwich—39.6°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, January 25 (6 P.M.): Max. 48°; Min. 43°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 26 (10 A.M.): Bar. 30.4; Temp. 50°; Weather—Overcast.

PROVINCIALS.—Wednesday, January 25: Max. 43 Scot-land N.; Min. 40° Doncaster.

SALES FOR THE ENSUING WEEK.

- MONDAY AND FRIDAY—
Herbaceous and other Plants, Hardy Bulbs, &c., at 12; Roses, Fruit Trees, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.
- WEDNESDAY—
Hardy Bulbs and Plants, Border Plants, &c., at 12; Roses at 1.30; Japanese Lilioms at 2.30; Palms and Plants at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.
- WEDNESDAY TO FRIDAY—
Imported 3-day Sale of Nursery Stock at the Nurseries, South Woodford, by order of Mr. J. Fraser, by Protheroe & Morris, at 11 o'clock.
- FRIDAY—
Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Gardeners' Benevolent.

On two occasions during the year the affairs of the Gardeners' Royal Benevolent Institution are matters of special public interest. In January, at the annual meeting, the Executive Committee gives a detailed account of its stewardship, whilst later, generally in May, the holding of the festival dinner provides an opportunity for making a general appeal for donations to the funds. The meeting which took place last week was held for the purposes of receiving the Committee's report and electing new pensioners. We publish on another page the full text of the report and the details of the balance-sheet, in order that those who are not connected with the institution may see exactly what the items of receipts and expenses have been during the past year. If these matters are studied carefully, we believe that they will be found to be so satisfactory as to impress favourably the minds of gardeners and others who are not indisposed to assist a charitable cause, if it can be shown that the objects are laudable, that they closely concern themselves and their colleagues, and that the management is carried out with intelligence, enthusiasm, and economy.

In the first place, as Mr. Veitch pointed out in his address, the institution has been able to expend larger sums in the relief of distress

than in any previous year. The number of pensioners at the commencement of 1910 was 240, including 141 men and 99 widows. This number constituted a record, and, therefore, the responsibilities of the Committee exceeded anything in the history of the institution. When it is realised that in 72 years the Benevolent has distributed upwards of £172,000 in the relief of necessitous gardeners and their widows, there are certainly good reasons for the hopeful spirit so characteristic of those friends of the institution who are working hard to accomplish greater results every year.

At the end of each year, the Committee has to take into very careful consideration the financial resources at its command, and measure liabilities with a view to determining how many fresh pensioners it can safely recommend the subscribers to place upon the funds. Our readers are already aware from the election results published in this journal last week that this year the Committee recommended the election of 20 candidates, thus making the number on the books 245, which is more than on any previous occasion. By thus again increasing the permanent liability the Committee has to appeal to subscribers and the public for increased support. The annual disbursements are considerably over £1,000 a year, whilst the sum obtained from annual subscriptions amounts to but little over £1,500. The great deficiency has, therefore, to be made up by collections at the annual festival, by dividends, and in any other way the Committee can devise. It has also to be remembered that, when once the institution has placed a pensioner upon its books, it has assumed a moral responsibility to continue that pension until the decease of the beneficiary.

Turning from the pensioners fund to the Victorian Era and the Good Samaritan Funds, it is satisfactory to note that in both cases the Committee has distributed the income very liberally. It is not empowered to spend the capital of these funds, but the dividends only, and in each case the amount distributed during the year is very nearly equal to the receipts. We believe that this policy is well calculated to stimulate the liberality of subscribers, for nothing is more discouraging to public charity than the fact that a particular institution is more concerned with nursing its funds than in the relief of distress, for this latter work alone justifies its existence. It is interesting to note that the Samaritan Fund has benefited to the extent of £62 17s. owing to the receipt of the balance of the "Harry J. Veitch portrait fund."

We read in the report of the losses the institution has suffered during the past year through the death of some of its principal subscribers. The chief of these was Baron Schröder, who bequeathed a legacy to the Benevolent of £1,000. Baron Schröder's name will be permanently remembered by the Schröder pensionship which has been established by the Royal Horticultural Society, partly in recognition of the services Baron Schröder rendered to the Society in connection with the erection and equipment of the hall in Vincent Square. Another pensionship established during the year is a tribute to the memory of William and David Thomson, two Scottish gardeners who are amongst the most renowned in the history of British horticulture.

The results of this year's election and annual meeting were better than the Committee anticipated at the time the ballot papers were distributed. There were 22 new pensioners elected instead of 20, another candidate was given a pension for the year owing to the generosity of Mr. Arthur W. Sutton, and Mr. George Monro offered to satisfy the present needs of still another candidate. Then, at the annual friendly supper, it was announced that Mr. George Monro would give a sovereign each to 40 of the most necessitous candidates who had failed at the election, in celebration of the fact that Mr. Monro has been 40 years in business. Mr. N. N. Sherwood contributed further to the success of the day by giving a pension of £20 to another candidate, whilst Mr. Joseph Rochford contributed a similar amount to the Good Samaritan Fund.

But when all these generous acts are added to the election results, there are still nearly 50 candidates who are denied the full benefits of the institution for at least another year. This fact should be sufficient to induce gardeners to do their very utmost to subscribe their guinea to the funds. Many of them are subscribing from year to year, but others who, it may be assumed, are just as well able to do so have so far neglected their duty in this matter. We trust that some means may be devised which will awaken them to a knowledge of their indebtedness to those who are working strenuously to mitigate the sufferings of their colleagues, and that they will be induced to respond, in some way or another, to the appeals which are made to them from time to time.

The next annual festival dinner will be held in the Grocers' Hall on May 23, under the presidency of Sir Marcus Samuel, Bart. Let all do their utmost to make that occasion memorable in the annals of the institution, memorable for its record contribution to the funds, and also for the fact that gardeners themselves show their appreciation of the services which the institution renders them by contributing in larger numbers than hitherto.

Sir Francis Galton.

In the death of Sir Francis Galton, F.R.S., which took place at Grayshott House, Haslemere, on January 17, British science loses one of its most distinguished ornaments.

Sir Francis Galton, who lived to the advanced age of 89, was remarkable not only by reason of the importance of his contributions to science, but also by reason of his versatility. A cousin of Charles Darwin, he was, like Darwin, a Cambridge man, and though he was compelled, because of ill-health, to take a "poll" degree, he lived to avenge that fate by gaining what is perhaps the highest honour which the University can bestow—"an honorary fellowship of Trinity." Though he made valuable contributions to many branches of science, it is probable that Galton's fame will rest on the pioneer work he did in the investigation of the great problems of heredity. He was among the first—if not actually the first—to apply statistical methods to the solution of these problems, and the results of his labours are published in several brilliant books: *Hereditary Genius: An Inquiry into its Laws and Consequences*—of which Darwin said: "I do not think I ever in my life read anything more interesting or original;" *English Men*

M. J. Welch.

of Science, their Nature and Nurture, and others of no less importance.

The conception of "discontinuous variation," which has played such a prominent part in recent theories of heredity, is clearly indicated in Galton's *Natural Inheritance*, as also is Weismann's theory of the continuity of the germ plasm.

All through his long life Galton not only played an important part in the investigation of the phenomena of heredity and variation, but he strove—as the titles of his works already cited show—to apply a knowledge of these phenomena to the human race. Certain that the race has to no small extent its destinies under its own control, he not only pleaded for wiser rules and laws, but founded a research fellowship in the University of London for the study of eugenics, the holder of the fellowship to devote himself to the study of "the agencies under social control that may improve or impair the racial qualities of future generations, either physically or mentally."

Among other of Galton's notable contributions to science may be mentioned his meteorological work—the term anticyclone now in general use is due to him, as are also the charts used in weather prediction—and the system of identification of individuals by finger prints in use by the Home Office of this country.

It is interesting to note that though Galton achieved such remarkable scientific work, and though academic honours were showered thick upon him, no official recognition of his services to the State was made till he had reached his 88th year, when he received a knighthood.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will take place on January 31. In the afternoon a lecture on colour photography will be given by Mr. W. MARSHALL.

PROPOSED NATIONAL DAFFODIL SOCIETY.—A movement is taking place with the object of establishing a National Daffodil Society, with its headquarters in London. A preliminary meeting of those most intimately connected with the flower will be held before very long, and if the result is satisfactory, as it is believed it will be from the promises of support already received by the promoters, a public meeting is to be called on one of the days of the R.H.S. Spring Bulb Show, March 14-15, for the further consideration of the matter. Without in any way encroaching on any of the local societies, it is thought that there is ample scope for such a body. A great Daffodil Show at Vincent Square ought to be a regular event, and a Year Book, in which everything of general interest might be focussed, seems to be a real want among the Daffodil community.

GEORGE MONRO CONCERT COMMITTEE.—The 15th annual concert organised by this committee will be held on Thursday, February 16, at the Queen's Hall. Mr. GEO. MONRO is expected to preside, and many of the best concert artistes have been engaged, as well as the Band of H.M. Coldstream Guards. The balance sheet of the 14th concert, held last year, is before us, and we note that the cash carried forward is £63 6s. 11d., and that £39 18s. has been given by the committee to charities. The Gardeners' Royal Benevolent Institution received the sum of £12 12s., and the remainder was divided among various other organisations.

YORKSHIRE GALA.—The 53rd annual show will be held on June 14, 15, and 16, in Bootham Park, York. The schedule embraces 82 classes, and all sections of gardening are represented. In the plant classes, a sum of £20 is offered as the first prize for a group of miscellaneous plants, in or out of bloom, arranged for effect. There are five other prizes in this class, the six being of a total value of £70. Provision is also made for smaller exhibits of this character, the first prize being £12. The rock-garden exhibits are important features of these York shows and a first prize of £15 is offered for an exhibit measuring 30 feet by 12 feet. On this occasion, no digging is permitted, so that greater trouble will be encountered in forming water pools and streams. Specimen plants are another feature at York Galas, but some better system of staging them is necessary, as they are generally arranged without any method. The president, Lord MIDDLETON, offers a special prize for the most meritorious and attractive exhibit in the show. Four gold medals

co-operative store, a bacon-curing factory, a fruit-bottling works in operation, collections of every kind of farm implement, and so forth. Beyond this, the land will be seen under cultivation, and special attention is being paid to intensive gardening. In addition to intensive cultivation of the soil, there will be various plots of ground, ranging in size from 10 perches to half an acre, treated with approved forms of manure and fertiliser, and planted with market crops.

THE MANURIAL VALUE OF SOOT.—Apart from its deterrent action on insect pests, soot has a definite value as a manure depending upon the ammonium salts which it contains. Soot varies very much in density, and it has been generally accepted by farmers that a light soot is the best. Mr. H. W. HARVEY, of the Cambridge School of Agriculture, in the course of a recent investigation, has discovered the interesting fact that there is a relation between the content of nitrogen and the weight per bushel. As

FIG. 29.—OLEARIA MACRODONTA IN GLASNEVIN BOTANIC GARDENS, DUBLIN.

(See p. 53.)

will be awarded to trade exhibits, in different sections. Copies of the schedule may be obtained from the secretary, Mr. FRED. AREY, Davyhall Chambers, York.

SMALL HOLDINGS.—A Small Holdings Exhibition will be held in the Crystal Palace grounds in connection with the Festival of Empire, and no detail of country life will be omitted. The Small Holding section will be laid out as a small holders' colony and model village in miniature. It will be at work all day, peopled by farmers and stocked with the best cattle and material. A small holder's homestead is to be erected, and around it will be barns, ricks, cow-yards, piggeries, sheep and goat-pens, labourers' cottages, a dairy, stables, poultry-runs, duck ponds, beehives, and pigeon lofts. In another part of the ground there will be a milk collecting station and an egg collecting depot to show how small holders should co-operate for their mutual benefit; the village hall,

a rule soot contains about 1 lb. of nitrogen per bushel. On this basis soot is worth about 6d. per bushel for its fertilising value, apart from its value as an insecticide. Moreover, it appears to follow from the above that soot should be bought by volume and not by weight.

SIMPLE LIFE CONFERENCE AND EXHIBITION.—The Simple Life and Healthy Food Conference and Exhibition will be held in the Caxton Hall, Westminster, on March 21, 22, 23, and 24 next. The objects of the conference and exhibition are to simplify modern life, to introduce into homes healthy food and hygienic decorations, to teach rational physical culture, and to inculcate a love of simple and beautiful architecture. Amongst the lecturers may be mentioned Dr. STENSON HOOKER, Dr. JOSIAH OXFIELD, Dr. A. B. OLSEN, Dr. REINHARDT, Dr. ROBERT BELL, and EUSTACE MILES. Season tickets may be had for 6d. from the Simple Life Exhibition, 22-24, Gt. Portland Street, W.

NEW ZEALAND PLANTS.

(See Supplementary Illustration.)

The plants enumerated in the list printed below are believed to be new introductions into the British Isles. They were brought to England from New Zealand in February, 1910, and represent the result of my second expedition in search of plants, from which I returned with some 2,000 plants, comprising 217 species. The results were not quite so successful as those of my previous expedition, mainly owing to the fact of my having to bring them across the tropics at a more unfavourable time of year, and also because I had more difficult subjects to bring; a great many of them being natives of the higher alps of New Zealand. I lost some 45 species entirely. I am glad to say, however, that the main object of my journey, namely, to obtain *Olearia semidentata*, was successfully carried out. An account of my expedition thither has appeared in the *Kew Bulletin*. This plant I have established at Tresco, where it is now thriving, and several cuttings have been rooted. *Angelica* (*Ligusticum*) *Diellenbachii*, a rare and interesting plant belonging to the Umbelliferae, has also been established, and two new species of *Veronica*, namely *V. Bollonsii*, from the Poor Knight Islands, and *V. Astonii*, found by Mr. B. Aston towards Cape Palliser in the S.E. side of the North Island. Besides these, were many Australian plants and a large collection of seeds from West Australia. The photograph of *Olearia semidentata* (see Supplementary Illustration) shows a plant growing in the upland bog of the Chathams.

LIST OF NEW ZEALAND PLANTS INTRODUCED IN 1910.

<i>Angelica</i> (<i>Ligusticum</i>) <i>Diellenbachii</i> .	<i>Paratropis macrophyllum</i> .
<i>Asplenium montana</i> .	<i>Pennantia corymbosa</i> .
<i>Celmisia laricifolia</i> .	<i>Podocarpus acutifolia</i> .
" <i>prorepens</i> .	<i>Pentachondria pumila</i> .
" <i>pseudo-Lyallii</i> .	<i>Pratia arebana</i> .
" <i>Rutlandii</i> .	<i>Pterostylis Banksii</i> .
" <i>viscosa</i> .	<i>Quintinia acutifolia</i> .
" <i>sessiliflora</i> .	<i>Ranunculus lobulatus</i> .
<i>Dracophyllum arboreum</i> .	" <i>Sinclairii</i> .
" <i>paludosum</i> .	<i>Raoulia grandiflora</i> .
" <i>Kirkii</i> .	<i>Rubus Barkeri</i> .
<i>Fuchsia excorticata</i> purpurea.	" <i>parvus</i> .
<i>Fagus Solandri</i> (purea).	<i>Senecio Kirkii</i> .
<i>Gentiana bellidifolia</i> .	<i>Samolus repens</i> , var. <i>Chathamensis</i> .
<i>Leucopogon fasciculatus</i> .	<i>Veronica Astonii</i> (mitica).
<i>Olearia semidentata</i> .	" <i>amplexicaulis</i> .
<i>Onuris Colensoi</i> .	" <i>Bollonsii</i> .
<i>Pinnaea longifolia</i> .	" <i>Buchanani</i> .
" <i>Gndia</i> var. <i>pulehia</i> .	" <i>Wilcoxii</i> .

Arthur A. Dorrien Smith.

SCOTLAND.

SAUGHTON PARK, EDINBURGH.

SAUGHTON PARK, Edinburgh, which is one of Scotland's finest public parks, frequently engages the attention of the Corporation of Edinburgh and its Parks Committee. Among other questions, that of the utilisation of the old mansion house of Saughton, a seventeenth century building, has frequently been under the consideration of the committee. At a recent meeting a report upon the question was submitted, suggesting that a portion of the newer wings should be converted into dwellings for some of the members of the staff, that part of the older building might be utilised for public shelters, tea rooms, &c., and that other portions might be used for exhibiting objects of interest. In the meantime, the city gardener, Mr. J. W. McHattie, has been asked to report upon the cost of altering the east and west wings to provide dwellings for some of the members of the park staff.

PRESENTATION TO A GARDENER.

At the recent annual meeting of the Dunfermline Horticultural Society, advantage was taken of the opportunity to present a testimonial to Mr. John Brown, gardener to Mr. William Black, of Chapel, Kingskettle, Fifeshire, and formerly gardener at Middlebank. Mr. Brown

has for 17 years been one of the best exhibitors at the Dunfermline shows, and he has rendered valuable services to horticulture in the district. The gift took the form of a gold Albert and appendage, and was handed to Mr. Black by the president of the society.

GRANT TO SCOTTISH HORTICULTURAL ASSOCIATION.

At the last meeting of the Town Council of the City of Edinburgh, the usual grant was made to the Scottish Horticultural Association for their Chrysanthemum Show in November. The amount is £25, and is an evidence of the interest taken by the Corporation in the success of the show.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

FRUIT TREE STOCKS.—With reference to the letters which have appeared on this subject from Messrs. H. Somers Rivers and R. P. Brotherton (see vol. xlviii., pages 371 and 372), I have been looking carefully through some old books for information of the early history and cultivation of the Potato, and in one volume dealing with horticultural matters, published in 1697 by Thomas Tryon, and printed at that date for Geo. Conyers at "The Ring" in "Little Britain," I find much that is interesting. While many of the statements and recipes contained in its pages cannot be regarded as otherwise than apocryphal, yet there is much that is written in a practical and clever manner, and an extensive knowledge of flowers, fruits, vegetables, and herbs, together with their cultivation, is displayed by the author. Despite the quaint terminology of the period, one is impressed with the great variety of vegetables grown at that time, and, contrary to expectation, I find that the Potato appears to have been in fairly general cultivation. In dealing with the methods employed in grafting and budding, after a full and lucid account, the writer closes his chapter as follows:—"In grafting, the Figg will grow upon the Mulberry, the Apple or Pear upon the Quince, the Damson upon the White Thorn, as likewise will the Peach and Cherrie upon the Peach, the Apricot upon the Plum, the Walnut upon the Ash, the Quince upon the Barberry Tree, the Almond upon the Filbert, the Vine upon the Cherrie tree, and so of others, which by grafting are bettered and improved." From a chapter on the subject in this old book, I gather that Vines were grown in the open, and wines were distilled from their produce, but, owing to meteorological conditions, those obtained from France and Spain were considered of better quality. *Geo. M. Taylor, Mid-Lothian.*

AWARDING CERTIFICATES TO PLANT NOVELTIES.—The purpose of the newly-formed Hardy Plant Society to make awards in the form of certificates to new hardy plants, no doubt follows on the lines of some other special societies in making similar awards. It is announced also that a newly-formed Horticultural Society in the North proposes to establish committees on the basis of the old established committees of the Royal Horticultural Society for similar objects. We see the Rose, Dahlia, Carnation, Sweet Pea, Chrysanthemum, and other special societies acting in a similar manner in making awards of certificates, and various other bodies will doubtless in time follow suit. Is there not danger that with so much overlapping of the work undertaken by the Royal Horticultural Society very great confusion may ultimately arise? I do not suggest this in any spirit of jealousy, because every society has the fullest right to take any course the members think proper. But the point for consideration is which of the various societies' awards are to be regarded as having the greater value? No other society has at its disposal more experienced committee men than the Royal Horticultural Society. Does the action of these various societies in thus granting awards to novelties tend in any way to lower the value which hitherto has always attached to those of the Royal Horticultural Society? If any subjects passed over at Vincent Square because they are considered unworthy of

an award receive recognition elsewhere, then a very absurd position will be created. As one intimately associated with the National Vegetable Society, I may state that the society confers no certificate or award to novelties. Those are left to the jurisdiction of the R.H.S. Fruit and Vegetable Committee, notwithstanding that the National Vegetable Society gives marks of commendation if a variety of vegetable is found worthy after trial—a very different thing. *A. Dean.*

APPLES: IMPORTED AND HOME-GROWN (see p. 45).—Mr. Bartlett rather shocks one's view as to what is British when he describes the superb Apples which come to us from Canada, British Columbia, and Tasmania as "foreign." Did he use the term "imported" criticism would be disarmed. But that it is possible to have superb home-grown Apples in mid-winter was evidenced at the recent R.H.S. meeting, when Messrs. Veitch, Bunyard, and Seabrooke staged some 300 dishes of really fine fruits. Moreover, an attendant of one collection informed me that he was overwhelmed with requests to sell. That fact shows that when home-grown fruits are presented to the public in an attractive form they find plenty of purchasers. But then the public never sees home-grown Apples in shops or markets presented in the way they are shown at Vincent Square, or even like the imported fruits presented to them in tubs and boxes. It is stated that a Midland grower has recently been selling fruits of Bramley's Seedling to the extent of 3,000 bushes at 7s. 6d. per bushel! *A.*

DIJON TEA ROSES.—I should like to know by whose authority this term is given to a certain group of climbing Roses. Surely it is the height of absurdity to class tender varieties, such as *Henriette de Beauvean*, *Climbing Devonensis*, and *Climbing Niphetos* as *Dijon Teas*, which is tantamount to saying they possess the attributes of hardiness which this grand old Rose represents. *Henriette de Beauvean* is exceedingly tender, although a real beauty so far as colour is concerned. Why not drop the word "Dijon" Tea, and substitute instead *Climbing Tea*, or, if the term must be used, let the class be revised, and eliminate such sorts as I have named and include *Reine Marie Henriette*, *Francois Crousse*, *Mme. Hector Leuilliot*, *Johanna Selus*, &c., which appear to me to rightly belong to the group? I am glad to see a word of appreciation from Mr. Woodall (see p. 20) of *La France de '89*, and I can endorse all that he says in favour of it. He is wrong, however, in giving Nabouland the credit of raising the variety, for I believe it was Moreau-Robert who introduced this Rose. It is a splendid Rose for a wall, much superior to *Reine Marie Henriette*, which mildews so badly, although, of course, the latter variety would cover more wall space than *La France de '89*. *Walter Easlea, Duncroft, Eastwood.*

AMERICAN GOOSEBERRY-MILDEW.—In your issue of January 7 (p. 13), a correspondent states: "During December this pest made a rapid development. Quarters of Gooseberry bushes that I inspected at the end of November and found free from the disease were, by the middle of December, badly affected." Now, at that season (December), Gooseberry bushes are usually in a dormant state, therefore it is not clear how the mildew develops. I have never found the disease develop later than September, or early in October; but I have found the "summer stage" of the disease on the berries as early as the third week in May. At the Hexham conference, Mr. E. S. Salmon, referring to this disease, said in his lecture: "Two distinct stages may be observed. In the first stage, the so-called 'summer stage,' the fungus forms enormous numbers of very minute spores, or seed-like bodies, by means of which the disease is spread rapidly. In the second stage, the so-called 'winter stage,' the fungus forms winter spores. These winter spores have the function of keeping the fungus alive, though in a dormant condition, through the winter months." This would lead one to believe that the fungus remains dormant during the winter. If, as your correspondent states, the mildew develops in the winter also, it will be a serious matter for all growers of this popular fruit. It is a disease that growers should endeavour by every means to exterminate before it becomes widespread. *G. D. Belfast.*

RAINFALL IN 1910.—The following particulars of the year's rainfall prove that this part was one of the wettest districts in the country. The total fall amounted to 91.9 inches, there being 238 wet days. The following months were particularly wet.—January (28 days), February (28 days), March (20 days), April (27 days), August (24 days), and December (23 days). In February rain fell on every day to the aggregate depth of 12.36 inches. The total fall registered in January was 10.93 inches, and in December 9.37 inches. September was the driest month, with only 10 wet days. *P. Hills, Kinloch Castle Gardens, Rhum by Oban.*

LASIANDRA MACRANTHA.—In the Winter Garden, Springburn Park, Glasgow, I noticed recently a particularly well-cultivated specimen of this species covering a space approximately 25 feet by 3 feet. It is planted out at the base of one of the pillars which support the gallery, which runs round the building. Thus planted out and allowed to grow naturally, it is very effective. It may, however, be grown and flowered quite satisfactorily in a young state as a pot plant, for which phase of culture the variety *L. m. floribunda* is more suitable than the type. In the case of the type plant, cuttings, rooted early in the year, if pinched occasionally during the summer, will make specimens of a useful size for flowering in late autumn. These may be potted and grown on for a second year, persistently pinching as before, after which time they are usually too large, except for special purposes. *Fred. W. Jeffrey, Renfrewshire, N.B.*

SHRUBS IN FLOWER AT ST. TUDY.—Among the noteworthy shrubs in full flower here on January 20 were those mentioned below. *Rhododendron lapponicum* is a dwarf, evergreen plant, with small, dark leaves, greyish on the underside, and having purple flowers. The flowers are produced eight or nine in a truss, and are each about half an inch across. This is an ideal plant for the rock-garden, and gives colour at a season when it is most appreciated. *Rhododendron mucronulatum* is a loosely-branched, deciduous shrub, now about 3 feet high. It is starred all over with its little, purple, butterfly-like flowers, individually about an inch across, and somewhat salver-shaped. Of this plant I do not know the native country, and should be grateful if someone would enlighten me. [Central Asia.—Eds.] Then there is *Berberis Bealei*. This has leaves like *B. Aquifolium* on a large scale, and flowers of a rich, cream colour, produced in numerous spikes lying horizontally on the top of the upright branches. The great attraction of this plant is its exquisite scent, which is rather like that of Lilies of the Valley, and its only drawback is that it is impossible to cut the flowers unless one is prepared to behold the plant. *E. M., Lamellen, St. Tudy, Cornwall.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 17.—*Present:* Mr. E. A. Bowles, M.A., F.L.S. (in the Chair); Dr. J. A. Voelcker, Messrs. J. T. Bennett-Poe, A. D. Michael, C. E. Shea, A. Worsley, W. Hales, H. J. Elwes, J. Fraser, W. C. Worsdell, R. A. Rolfe, and F. J. Chittenden (hon. sec.).

Sap exudation in Elm trees.—Mr. J. FRASER, F.L.S., showed a piece of the bark of an Elm tree perfectly white, part of a strip extending down the trunk of a tree from a small wound some distance up. He remarked that wounds in Elms may bleed for several years, as they often take many years to heal. The white appearance of the strip was due to the death of the green alga which covered the trunk elsewhere, but which, where the sap flowed, had been destroyed. Mr. FRASER thought that possibly the sap of the tree itself had had an injurious effect upon the alga.

Azalea gall.—A galled growth from *Azalea indica* came from Cheltenham. The whole of the leaves at the tip of a shoot had become greatly and uniformly thickened, and were covered with a whitish "bloom." These galls

are due to the attack of the fungus *Exobasidium japonicum*. The only remedy is to pick off the galled growths and burn them.

Coloration of Bean seeds.—Mr. CHITTENDEN showed a series of seeds of French Bean grown at Wisley in the past summer from seed shown before the Committee last January, when its history was given. The parent seed was the result of an accidental cross in 1907, and the progeny had segregated in 1909. The seeds sown and the seeds produced in 1910 were as follow:—

(a) Parent seeds black: *Plant 1* produced 28 black seeds, 25 partly chocolate, partly black, 35 brownish black. *Plant 2* pro-

FIG. 30.—OLEARIA MYRSINOIDES.

(See p. 53.)

duced 52 seeds like parent. *Plant 3* produced 285 seeds like parent. *Plant 4* produced 46 seeds brownish black.

(b) Parent seeds creamy white: *Plant 1* produced 170 seeds purplish, tinted white, with mottling and spots and streaks of black, 55 black or reddish black with small spots of purplish white. *Plant 2* produced 100 seeds fleshy white. *Plant 3* produced 90 seeds creamy white, 5 flesh white.

(c) Parent seeds tan: *Plant 1* produced 25 seeds chamois. *Plant 2* produced 22 seeds dead-leaf brown with tiny spots fleshy white; 32 little lighter than foregoing with large number of spots and blotches of fleshy white, the blotches speckled with ground colour; 7 brownish terra cotta with tiny spots of

fleshy white; 35 terra cotta with spots and blotches of fleshy white speckled with terra cotta. *Plant 3* produced 72 seeds chamois to dark hazel. *Plant 4* produced 115 seeds chamois, more or less mottled with black.

- (d) Parent seeds maroon: *Plant 1* produced 135 seeds bistu to dark tan. *Plant 2* produced 25 seeds purple black to buff. *Plant 3* produced 35 seeds dark steel blue to lighter purplish blue. *Plant 4* produced 195 seeds purple black to snuff colour. *Plant 5* produced 135 seeds like plant 2.
- (e) Parent seeds reddish salmon with streaks of burnt umber: *Plant 1* produced 173 seeds yellowish salmon with many streaks of fawn (like parent); 13 seeds fawn, except for few small spots of pale yellowish salmon. *Plant 2* produced 156 seeds like striped ones of plant 1. *Plant 3* produced 170 seeds pale yellowish salmon with faint grey mottling, striped with burnt umber; 6 wholly burnt umber, except for few small spots of pale yellowish salmon.
- (f) Parent seed pale flesh with streaks of dark neutral tint: *Plant 1* produced 85 seeds pale putty to cinnamon. *Plant 2* produced 230 seeds pale flesh mottled and more or less streaked with neutral tint (like parent).
- (g) Parent seed chocolate: *Plant 1* produced 55 seeds Naples yellow more or less mottled with neutral tint. *Plant 2* produced 22 milk-white seeds.
- (h) Parent seed violet black with streaks and spots of rosy white: *Plant 1* produced 100 seeds milk white to creamy white. *Plant 2* produced 9 seeds milk white; 81 greenish white. *Plant 3* produced 128 seeds with rosy-white ground mottled and streaked with violet black so that seed appeared purple. *Plant 4* produced 195 seeds similar to plant 3, but less mottled.
- (i) Parent seed rosy white with more or less ivory black: *Plant 1* produced 45 seeds of rosy white faintly mottled with dilute black and blotched and streaked with violet black. *Plant 2* produced 11 seeds fleshy white. *Plant 3* produced 175 seeds with rosy-white ground, some half, some almost entirely covered with greenish black. *Plant 4* produced 75 seeds similar to those from plant 2, but faintly mottled with grey. *Plant 5* produced 90 seeds with very pale rosy-white ground mottled with much diluted violet black and with streaks of violet black. *Plant 6* produced 41 seeds violet black speckled with rosy white; 48 violet black more spotted with rosy white; 20 seeds neutral tint with small spots of rosy white; 52 neutral tint with large spots of rosy white; these differences were not clearly marked, however.
- (j) Parent seed burnt umber: *Plant 1* produced 370 seeds maroon. *Plant 2* produced 90 seeds milk white faintly mottled. *Plant 3* produced 290 seeds fawn. *Plant 4* produced 398 seeds maroon.
- (k) Parent seed pale flesh with large spots, streaks and specks of burnt umber: *Plant 1* produced 42 seeds pale flesh with streaks of lilac rose. *Plant 2* produced 98 seeds pale flesh, some almost wholly, others half covered with tan. *Plant 3* produced 48 seeds milk white; 90 sulphur white. *Plant 4* produced 225 seeds with pale flesh spotted with diluted umber and more or less covered with burnt umber, as in plant 2.
- (l) Parent seed chamois faintly mottled: *Plant 1* produced 93 seeds cream yellow to chamois, more or less mottled with olive brown. *Plant 2* produced 74 similarly-coloured seeds.
- (m) Parent seed pale blush with parts reddish black: *Plant 1* produced 195 seeds purplish tinted white, much or only half covered with darker spots and blotches. *Plant 2* produced 200 seeds milk white to yellowish white.
- (n) Parent seed dark chocolate brown with patches of dark fawn: *Plant 1* produced 305 seeds fleshy white with more or less chocolate brown.
- (o) Parent seed chocolate with small spots of rosy white: *Plant 1* produced 36 seeds chocolate. *Plant 2* produced 50 seeds chocolate.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

(ANNUAL MEETING.)

The results of the election were recorded in our last issue.

JANUARY 19.—The seventy-third annual meeting of the supporters of this Institution took place on the above date. The proceedings were reported in our last issue, and we now reproduce the report of the Executive Committee for 1910.

REPORT OF THE COMMITTEE.

Before presenting the report of their work for the year 1910, the committee desire to record their sense of the very great and sad loss the Institution sustained in the death of His Majesty King Edward, who, as Prince of Wales, was its president, and who subsequently as King honoured it by becoming its patron. His late Majesty had also for many years been a subscriber to its funds.

The committee are very gratified to announce that His Majesty King George, who, until he succeeded to the throne, was president of the institution, has graciously consented to become its patron, Her Majesty Queen Mary having also accorded her patronage.

The committee have great pleasure in submitting their 71st annual report, together with statement of the accounts as audited.

They are extremely glad to be able to state that the charity has during the past year more than ever justified its existence by meeting the increased and urgent claims of deserving and needy applicants, who, but for the aid thus rendered, would have been utterly stranded in their difficulty and distress.

It is now 72 years since the institution was founded, and during that time it has been able to distribute in relief upwards of £130,000, and at no other period in its history has it been able to do so much in affording timely aid to the necessitous horticulturist and his widow as in the year now closed.

At the beginning of 1910 249 persons (141 men and 107 widows) were in receipt of permanent relief by means of annuities of £20 and £10 respectively, in addition to other applicants financially assisted in other ways.

Of this number 22 have died during the year—13 men and nine women. Five of the men left widows, whose circumstances being such as to render them eligible, the committee at once placed them on the funds of the institution without election under Rule III, cl. 13, to receive the widow's allowance of £10 a year each.

There were therefore at the close of the year 225 persons receiving permanent relief, and to this number the committee recommend an election this day of 20 candidates from an approved list of 73 applicants, which will increase the number of beneficiaries to 245, being the greatest number there will ever have been at any time on the funds.

Although this further addition to the permanent liability naturally causes the committee considerable anxiety, they feel assured of the approval of the supporters of the charity, whose interest they confidently hope will be stimulated to still further exertions on its behalf.

With regard to the temporary assistance rendered to applicants, it would be impossible to over-estimate the importance and value in cases of emergency of the "Victorian Era" and the "Good Samaritan" Funds.

The former fund provides assistance to those unsuccessful candidates who have been subscribers to the institution and who are awaiting election. The latter fund gives immediate help to deserving applicants, whether they have been subscribers or not, in time of misfortune and distress. It would be difficult indeed to exaggerate the real benefit thus conferred on those poor people, and many are the grateful letters received from those who have been thus helped.

In connection with the "Good Samaritan Fund" the committee have much pleasure in acknowledging the receipt of £62 17s. the balance of the "Harry J. Veitch Portrait Fund," which the treasurer, the Rev. W. Wilks, requested might be so utilised.

It would perhaps be well to again remind the friends of the institution that the interest only from these funds can be used, and therefore any special contributions to either or both of them would be warmly welcomed and gratefully received.

The committee are pleased to report that the 71st anniversary festival dinner, held at the Hotel Metropole in June last, was very successful, and they gladly tender to the Hon. Harry Lawson, M.P., their grateful thanks for presiding on the occasion, and for his eloquent advocacy of the claims of the charity, as well as for his generous personal contribution to the funds.

The committee would also express their deep indebtedness to those gentlemen who were good enough to act as stewards or collectors; likewise to the horticultural Press for their gratuitous and invaluable assistance, to the donors of flowers; to those who kindly arranged the floral decorations; and to other friends for extremely useful services which were very much appreciated.

The committee gratefully acknowledge the kindness of those noblemen, ladies, and gentlemen who threw open their beautiful gardens to the public in aid of the fund of the institution, including the Right Hon. Earl Beauchamp, Madresheld Court, Malvern; the Lord Northbourne, Betchingham, Sandwich; Mary Countess of Ebeester, Holland House, Kensington; The Lady Battersea, Overstrand, Norfolk; Sir Frank Crisp, Finar Park, Houlby-on-Thames; and E. J. Wythes, Esq., of Epping.

The Messrs. George Munro, Ltd. Concert Committee again gave a portion of the proceeds derived from their well-known annual concert for the benefit of the funds, and the committee offer them their best thanks. It is sincerely hoped that other friends will emulate these examples.

The several auxiliaries have been well maintained during the year, proving a much-needed adjunct to the parent institution, and the committee desire most strongly to express their indebtedness to the following honorary officers for their kindly interest and much appreciated services, viz.:

BRISTOL AND BATH.

<i>Presidents.</i>	<i>Hon. Treasurers.</i>	<i>Hon. Secretaries.</i>
Col H. Cary Batten.	W. A. Garaway, Esq.	Mr. Geo. Harris.

WORCESTER.

Rt. Hon. Earl Beauchamp, K.C.M.G.	John White, Esq.	Mr. Percy G. White.
-----------------------------------	------------------	---------------------

BERKSHIRE, READING AND DISTRICT.

Mrs. Rowland Sperring.	Arthur W. Sutton, Esq., J.P., V.M.H.	Mr. L. Castle.
------------------------	--------------------------------------	----------------

LIVERPOOL AUXILIARY.

The Rt. Hon. The Earl of Derby, K.G.	Mr. A. J. Crippin.	Mr. R. G. Waterman.
--------------------------------------	--------------------	---------------------

The death roll in relation to the charity was a heavy one during the year. In addition to that of H.M. King Edward to which reference has already been made, the committee have to lament the loss of Baron Schröder, whose death was such a great blow to horticulture. He was a vice-president, and for many years one of the warmest and most generous supporters of the charity, to which he bequeathed a legacy of £1,000 duty free. As a tribute to his memory, and in recognition of his great service in connection with the erection and equipment of the horticultural hall and offices, the Royal Horticultural Society have established in connection with our institution a permanent annuity, to be known as "The Baron Schröder Annuity," the first recipient of which, nominated by the society, is Mrs. Wildsmith, the widow of a very highly esteemed friend of the charity.

The committee have further to regret the loss of two of their valued colleagues, viz., Mr. William Denning, who was a regular attendant at its meetings for many years, and Mr. J. M. Indoe, V.M.H., always ready to further in every possible way the interests of the institution; their presence and help are sorely missed.

Other sad losses are those of Mr. W. J. Nutting, formerly a member of committee, and for many years a valued subscriber, who passed away full of honours in a ripe old age; Mr. R. Wilson Ker, of Liverpool, Mr. J. L. Woodroffe, of Eastbourne, Mr. E. C. Mott, of Barnet, Mr. R. Blake, of Salisbury, and Colonel Hanbury Barclay, whose places it will be indeed difficult to fill.

A fund inaugurated during the year in memory of the late Mr. David Thomson has been successfully completed, and the amount raised has been added to that

In accordance with the rules of the Gardeners' Benevolent Institution, we have audited the accounts, and certify that they are correct and that our requirements as auditors have been fully met. We have also satisfied ourselves that the securities are in the hands of the bankers. We also wish to add that we find the books very well kept.

previously contributed with the same object to his brother, the late Mr. William Thomson's memory. The total sum has been invested to produce £20 a year to establish a perpetual annuity in memory of these two distinguished horticulturists, which will henceforth be known as the "William and David Thomson Memorial Fund," and a worthy old Scotch gardener living in Edinburgh in very distressed circumstances has been selected by the Messrs. Thomson's family representatives as the first recipient of the benefits thus established.

In consequence of the partial rebuilding of the offices until recently occupied, the Committee have been obliged to seek new premises, and they are glad to state that suitable quarters have been obtained at 62, Victoria Street, Westminster, close to Victoria Station, and not far from the former address.

The 72nd festival dinner in aid of the funds has been arranged to take place on Tuesday, May 23rd, next, the first day of the Temple Flower Show, when Sir Marcus Samuel, Bart., has very kindly promised to preside. The dinner will be held, by kind permission of the Guild, in the beautiful hall of the Grocers' Company, Princes Street, City, opposite the Bank of England.

It is hoped that this function will meet with much success and that the Chairman will be ably supported by every lover of gardening and flowers. Ladies and gentlemen are earnestly solicited to act as stewards on behalf of the festival.

In concluding their brief summary of the year's work, the Committee, whilst deeply thankful for what they have been able to accomplish, deplore their inability, from want of funds, to meet the claims of many other deserving applicants that come before them. They would, however, remind the friends of the Institution that at each election for the past 20 years the liabilities have been increased and the number of annuitants on the funds added to. They therefore plead most earnestly that a larger measure of support may be forthcoming in order that the work of this National Horticultural Charity, which has been carried on with such gratifying results for 72 years, may not only be maintained, but may be still further enlarged.

HARRY J. VEITCH,
Treasurer and Chairman.
GEORGE JINGRAM,
Secretary.

THE DINNER.

In the evening of the same day the committee and a few friends met at dinner at Simpson's, under the chairmanship of Mr. Joseph Rochford. After the Royal toasts, the Chairman proposed the toast of the evening, "The Institution." He said that it was a mistake to suppose that, because of the Old Age Pensions, such institutions as the Gardeners' Royal Benevolent were less needed than formerly, for the need was greater than ever. He spoke in appreciative terms of the gardener, and pleaded for greater liberality in order to help him in his distress. He (Mr. Rochford) said that they were all sorry that Mr. George Monro was prevented by illness from attending that meeting. Mr. Monro had empowered him to announce that he desired to give a sovereign each to 40 necessitous candidates to celebrate the fact that he had been in business for 40 years. Mr. Harry J. Veitch responded to the toast. He stated that in consequence of two deaths, they had elected 22 fresh candidates that day instead of 20. Mr. Sutton had provided for one more, Mr. Monro would look after the immediate needs of Mrs. Baillie, and Mr. Joseph Rochford had promised a donation of £20 to the Samaritan Fund. He also referred to the Schröder and Thomson annuities, and stated again what was said at the annual meeting in respect to a new by-law which would have the effect of giving the fresh pensioners one half of the first quarter's pension within a few days after the election. Mr. N. N. Sherwood proposed the toast of "The Committee." He referred to some of the former members of the committee and to the success that had been obtained. He suggested that ladies should be invited to the festival dinner to be held in the Grocers' Hall in May. In conclusion, he said that he should be glad to give a sum of £20 to place another unsuccessful candidate on the list of pensioners. Mr. W. Y. Baker responded. He said that the work of the committee was a labour of love. Queen Mary lost Calais 350 years ago, and it was said that the word "Calais" was engraved on her heart. He was sure that on Mr. Harry Veitch's heart was engraved the Gardeners' Royal Benevolent Institution. The toast "Our Country Friends" was proposed by Mr. George Bunyard, and responded to by Mr. P. C. M. Veitch. Mr. William Atkinson proposed the toast of "The Chairman," and Mr. Joseph Rochford proposed the toast of "The Secretary," Mr. G. J. Ingram.

SCOTTISH HORTICULTURAL.

JANUARY 17.—The annual business meeting of this association was held in the hall of the Young Men's Christian Association, 14, St. Andrew Street, Edinburgh, on this date. Mr. Whytock, the president, occupied the chair, and there were present 140 members. The report by the council for the past session showed that there was a slight decrease in the membership as compared with the previous year, but the financial statement showed an increase of £23 11s. 8d. The surplus on the Chrysanthemum Show was £43 11s. 6d. The following office bearers were elected in the place of those who retire by rotation:—Honorary president, Sir John Gilmour, Bart.; president, Mr. W. H. Massie (whose portrait we have pleasure in giving); vice-presidents, Messrs. J. Phillips and W. G. Pirie; councillors, Messrs. J. C. Grieve, G. P. Berry, J. Hay, W. Smale, R. Cairns, J. Bruce, and W. Williamson.

The report by the committee appointed by the joint councils of this association and the Royal Caledonian Horticultural Society to consider the possibility of the amalgamation of the two societies was read to the meeting. The report stated that the committee were unanimously of opinion that it would be in the interests of horticulture

W. H. MASSIE.
(President of the Scottish Horticultural Association)

generally to have the work in Edinburgh carried on by one strong society rather than by two as at present, and if that were possible they would have no hesitation in advising the councils that such a scheme should be proceeded with. On considering in detail the possibility of effecting amalgamation, there were found to be three methods, namely:—

1. By the Royal Caledonian Society assuming the Scottish Association;
2. By the Scottish Association assuming the Royal Caledonian Society; and
3. By dissolving both societies and forming a new one.

The committee rejected 1 and 2, but gave very serious consideration to 3. When, however, they came to consider the dissolution of the Royal Caledonian Society, they were met with a difficulty. The charter gives the society no power to dissolve, and to do so without the authority of the Crown would involve the society in the risk of forfeiture of its funds. There was also a difficulty with regard to the Neill Fund, the management of which could not be transferred to a new society without the consent of the next-of-kin, who, so far, could not be traced. On application being made to the Secretary for Scotland to ascertain whether, and on what terms, the Crown would agree to a surrender of the charter, the reply received was to the effect that there was no precedent for such procedure,

and that the proposal was open to serious objections. The committee, therefore, reluctantly came to the conclusion that the only course open to secure the end in view was to obtain a new charter from the Crown incorporating both Societies, but they point out that the cost of obtaining such a charter would be somewhat serious, and as a charter is not so elastic as an ordinary constitution it tends to hamper the work of the Society. But even if such a course were adopted the new Society could not take over the management of the Neill Fund without the consent of the next-of-kin of Dr. Neill. It was agreed to continue the powers of the council to negotiate with the council of the Royal Caledonian Society regarding the matter.

The recommendation of the council to visit Manderston, Duns., on August 19, was agreed to.

Twelve new members were elected. The new President, Mr. Massie, will deliver his inaugural address on February 7.

HORTICULTURAL CLUB.

FLORA OF THE BERNESE OBERLAND.

JANUARY 17.—At a meeting of the members and guests of the Horticultural Club on the above date, the Rev. Canon Horsley, J.P., delivered a lecture on "The Scenery and People of the Bernese Oberland, including Swiss Plants." The lecture was illustrated by lantern slides, some of them taken by the lecturer himself, but most of them by Mr. Malby, of Woodford, and Mr. Ball, of the Glasnevin Botanic Gardens, Dublin, who accompanied Canon Horsley on his annual excursion into the Swiss Alps. The slides fell into three categories, namely (1) Alpine scenery, (2) flowers, photographed *in situ*, and (3), in some respects the most striking of all, a series of photographs taken in Mr. Malby's suburban garden at Woodford within an area of about 160 feet by 60 feet, in which Alpine scenery has been so artistically planned on a miniature scale and Alpine plants grown under such natural conditions, that photographs taken from judicious points of view and under conditions of haze and hoar frost (as illustrated in *Gardeners' Chronicle*, December 24, 1910, pp. 466, 467), were almost indistinguishable in effect from genuine Alpine scenery.

An interesting point in the Canon's address related to the rapid retreat of the Swiss glaciers up the valleys which they have shaped. Within his own memory the foot of one noted glacier is now a mile and a half from the point where he first visited it, and Mr. Charles E. Shea, who presided at this meeting, pointed out that this retreat is general, constituting an indication that the great recap, which in the so-called glacial period extended from the pole over all northern Europe and the greater part, if not the whole of Britain, and of which the existing glaciers represent but the fringe of the remainder, is very rapidly diminishing owing to some subtle change of climate.

Many of the Swiss flowers were beautifully shown in the slides, and each picture was accompanied by remarks relating to its habit and habitats. The curious fact that the *Soldanella*, of which two species were shown, actually thaws the covering of snow or even ice by self-engendered warmth, so that its charming flowers emerge into the sunshine, was described. In the subsequent discussion, in which Mr. Shea and Mr. Bilney took part, the mountain floras of other regions were compared with the Swiss. An exhibit was also made of a charming series of Swiss postcards depicting the Swiss floras in natural colours, and some independent photographs in natural colours were also highly appreciated.

NATIONAL VEGETABLE.

JANUARY 17.—A meeting of the committee was held on this date. The report of the sub-committee appointed to consider the schedule for the show to be held on August 30 was adopted with a few minor amendments. The total value of the prizes to be offered amounts to £240. Several new classes are to be provided. The schedule, with the reports of last year's trials, is ready for circulation, and all those desirous of obtaining a copy may procure one from the secretary, Mr. E. J. Quick, Kelmscott, Harrow View, Wealdstone.

SOCIÉTÉ FRANÇAISE D'HORTI- CULTURE DE LONDRES.

(ANNUAL MEETING.)

JANUARY 21.—The 22nd annual dinner of the Society of French Gardeners in London took place on the above date at the Café Royal, the president being Monsieur Philippe de Vilmorin, of Paris. In addition to the members of the Association there was a good company of English horticulturists present. The chairman proposed the toasts of the King, the Queen, and the Royal Family. Sir Albert Rollit next proposed the toast of the "President of the French Republic." He referred to the fact that on more than one occasion he had had the honour of being presented to Monsieur Fallières, and also to the former President, M. Loubet. To M. Loubet perhaps more than to anyone else we were indebted for the establishment of the Entente Cordiale, which had been one of the great securities of the world's peace, and which has tended to develop the trade between the two countries. Sir Albert Rollit said that they honoured M. Fallières as a ruler of a great, manly, and progressive people, to whom they owed many lessons and liberties. The toast was followed by the singing of the Marseillaise.

M. Philippe de Vilmorin then proposed the toast of the evening "the French Horticultural Society of London." In the first place, however, he referred to the illness of the Chairman of the Society, Mr. George Schneider, who, for the first time in the history of the institution, was absent from the annual gathering. M. de Vilmorin said that the Society and George Schneider were one and the same thing. Mr. Schneider was with them in spirit as they were with him. It was resolved that a message of sympathy should be despatched to him, signed by every person present. Proceeding to speak to the toast, M. de Vilmorin said it was due to the Society that he should express his regret that he was unable to be present last year, but whilst they were enjoying their dinner on that occasion, he was compelled by the disastrous floods in Paris to be engaged in saving his family and his home from destruction. However, the Consul General of France kindly took his place, and he felt that he owed to that gentleman a debt of gratitude. M. de Vilmorin thanked the Society for the generous donations that they had made to the Mansion House Fund for the relief of the distress caused by the French floods. The Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund had each been promised substantial donations, but at the last moment those donations were diverted from the English Charities to alleviate the French distress. He was sure that in the near future France would take its revenge for that act of generosity. The French Horticultural Society of London, continued to prosper; every day it was forging new ties between the two nations and, at the same time, it was helping young men who leave France to widen their knowledge and to gain fresh experience in their profession. It was obvious, however, that the Society could not do this good work unless it were given assistance by many of the great English firms of nurserymen and seedsmen. That was another reason for regretting the absence of their dear old friend Schneider. They must all be very thankful to him for what he had done. In conclusion the chairman said they would pray God that friend Schneider's illness would be a short one, and that he would soon be able once again to take his place at the head of the Society. He asked them to drink to the success of the French Horticultural Society of London, and to the restoration to health of their excellent chairman, George Schneider.

M. Louis Gentil, curator of the Botanical Garden, Brussels, and editor of *La Tribune Horticole*, expressed the regret he felt on arriving in London and finding his valued friend, the father and founder of the Society, confined to his bed by illness. By Mr. Schneider's desire he (M. Gentil) was placed next to the great Frenchman, who had so kindly consented to preside at that meeting. It was due to their absent chairman that the present meeting was such a successful event, and that the Society's progress was so satisfactory. He (M. Gentil) had lived for five years in England, and he could say that in many respects British horticulture was foremost in the world. Where, for example, could they see such

marvellous collections of Orchids as were frequently to be seen at the London exhibitions. He had great pleasure in proposing the toast of English Horticulture.

Mr. W. Hiehle next rose to state that the sum of £50, which it was intended, last year, to give to the English Horticultural Charities, had been diverted to another purpose, as the chairman had already explained. It was his (Mr. Hiehle's) privilege to say that at that moment they were in the happy position of being able to make good to the English Horticultural Charities the promise which was made to them a year ago. Consequently, the sum of £30 would be given to the Gardeners' Royal Benevolent Institution, and £20 to the Royal Gardeners' Orphan Fund. Mr. Edward Sherwood, the treasurer of the Royal Gardeners' Orphan Fund, thanked the Society on behalf of the Charities for the munificent donations, congratulating the members on being able to afford such substantial sums. The toast of English Horticulture was replied to by Mr. James Mc Kerchar, in a humorous speech, and in concluding he proposed the toast of "Past Chairmen."

Mr. Thomas Bevan, replying for "Past Chairmen," said that as a young man he knew what it was to live and work in a foreign country, and he could heartily appreciate, therefore, the work that the French Horticultural Society was doing. He well remembered the grand exhibits which MM. de Vilmorin et Fils contributed to the Paris shows 40 years ago.

The toast of "Our Chairman" was proposed by Mr. Arthur W. Sutton, who referred in appreciative terms to M. Philippe de Vilmorin and his father the late M. Henri de Vilmorin, paying a very high tribute to the great work that had been accomplished by the Vilmorin family. He referred to the advantages M. Philippe de Vilmorin had obtained by his education in England, to his industry in literary work, and to his scientific attainments. After the response by M. de Vilmorin, in which he said that he hoped the Vilmorins would continue to be honest men and leaders in horticulture, Mr. Harman Payne proposed the toast of the "Officers of the Society," and thanked M. Ripard for contributing the floral decorations.

M. Ripard responded, and proposed the toast of the "English Horticultural Press." Mr. R. Hooper Pearson, in responding to this toast, said that the Press was largely what the public made it. The Press was only too glad to record the good work of such societies as the French Horticultural Society of London. Those present were aware that an International Horticultural Exhibition was to be held in London in 1912. He could not help thinking that amongst the numerous visitors from abroad to that exhibition and congress there would be many who would gladly avail themselves of the opportunity to revisit England, because of their recollections of the happy hours they had spent here as members of this Society. In that way the French Horticultural Society would contribute to the success of the London International Exhibition. It was a fact that, of all the young gardeners who came to this country for professional experience, none looked forward with greater pleasure than their own members to revisiting England in later years. He (Mr. Pearson) congratulated the Society on having amongst its own sons a journalist of the type of M. Louis Gentil, of Brussels. They knew that he was charged with the practical management of the State Botanical Garden at Brussels, and that he edited and published a weekly horticultural journal. It said something for the ties of the Society that they were sufficient to bring such a busy man such a distance in order that he might attend their annual dinner. It was characteristic of Mr. Schneider that, notwithstanding his severe illness, the fact had been carefully kept from the knowledge of those likely to be present at that annual festival.

HASLEMERE CHRYSANTHEMUM.

JANUARY 21.—The annual meeting of this society was held on this date. The report showed that the exhibition had been successful and that there was a balance in hand of over £5. The secretary, Mr. J. Sharland, tendered his resignation, which was accepted with regret. Most of the other officers and committee were re-elected. It was decided to hold the annual show on November 9.

SOUTHAMPTON ROYAL HORTI- CULTURAL.

JANUARY 9.—The annual meeting of the above society was held at the Shaftesbury Hall, Southampton, on this date. The Mayor of Southampton presided. The report presented by the council stated that the past season had been remarkable for the excellence and extent of the several shows, more especially the Rose show and the autumn exhibition. Unfortunately the attendance of the public at all the shows was disappointing, and in consequence the council is compelled for the first time for some years to carry forward a few liabilities. In addition to the usual flower shows a garden fête is to be held in 1911.

The subscribers to the funds of the society number about 780, the total amount received from this source being £310 4s. The statement of accounts showed that the total receipts amounted to £722 12s. 6d. The expenses included, Rose show, £304 10s. 9d.; Carnation show, £130 15s. 10d.; autumn show, £154 16s. 5d.; and general account, £101 19s. 7d.

Mr. E. Kemp Toogood was elected chairman of the council, Mr. C. S. Fudge secretary for the 29th time, and the other officers and retiring members of the council were all re-elected with one exception. The secretary stated that 1912 would be the jubilee of the society, and expressed a wish that the event would be suitably celebrated.

ROYAL METEOROLOGICAL.

JANUARY 18.—At the annual general meeting of this society held on this date, the president (Mr. H. Mellish) said that the completion of the third decade since the society undertook the collection of climatological observations suggested that the moment was opportune for taking stock of the data which had been collected in the British Isles, and of the progress which has been made in reducing and discussing them, so he devoted his address to a consideration of the present position of British climatology.

Dr. H. N. Dickson, F.R.S.E., was elected president for the ensuing year.

BRIGHTON HORTICULTURAL.

JANUARY 19.—The annual meeting was held on this date in the Pavilion. Mr. W. Balchin occupied the chair. The report on the past year showed that the society had maintained a high standard of excellence at the flower shows, and had succeeded in materially reducing the loss on the year's working. The balance sheet placed the receipts at the Rose and Sweet Pea Show at £172 2s. 6d., and those at the Chrysanthemum Show at £204 15s. 9d. With the balance of last year, the donations, and other items, the receipts amounted to £708 5s. 3d. The expenditure at the Rose Show was £282 11s. 10d., and at the Chrysanthemum Show £257 13s. 3d., while the additional expenses incurred brought the total up to £654 3s. 10d., leaving a credit balance of £54 1s. 5d. The report and balance-sheet were adopted.

Alderman Colman was re-elected president; Mr. G. Miles treasurer and chairman; and Mr. A. J. Gaston secretary. The committee was also elected.

Forty-two new members were nominated during the meeting.

Obituary.

GEORGE HOBDAV.—A prominent amateur horticulturist has passed away in the death, on the 18th inst., of Mr. George Hobday, of Romford. The late Mr. Hobday, who was 60 years of age, was well known to frequenters of the R.H.S. meetings, and was a member of the Fruit and Vegetable Committee. He was also a member of the Committee of the National Vegetable Society, and of the Amateur Gardeners' Society, beside being connected with several local horticultural institutions in the Romford district. The funeral took place on the 24th inst., members of the National Vegetable Society, including Mr. A. Dean, the chairman, being present at the service. Amongst the wreaths was one sent by the National Vegetable Society.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending January 25.

The longest dry period for four months.—The last two days of the past week have been warm for the time of year, but previous to that the day temperatures continued low. On the coldest night the exposed thermometer showed only 11° of frost. On the 21st the difference between the highest and lowest readings in the thermometer screen was only 2°, which is an exceptionally low daily range for even a winter month. The ground is at the present time at about an average temperature at 2 feet deep, but 2° warmer than is seasonable at 1 foot deep. The dry period mentioned in my last report, if we except three days on each of which less than two-hundredths of an inch of rain was deposited, has now lasted for twelve days. We have to go back to September in last year, or for four months, in order to find so long a dry period. No measurable quantity of rainwater has come through either percolation gauge for the last five days. The sun shone on an average for 91 minutes a day, which is 14 hours a day short of the average duration for the latter half of January. On the first five days no sunshine at all was recorded. All the days of the past week were more or less calm. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 8 per cent. E. M., Berkhamsted, January 25, 1911.

COVENT GARDEN, January 25.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Eus.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices, including Anemone fulgens, Mimosa, Narcissus, and others.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and ferns and their prices, including Adiantum, Asparagus, and Ferns.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various potted plants and their prices, including Arabis Sieboldii, Euonymus, and others.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices, including Apples, Grapes, Lemons, and others.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices, including Artichokes, Beans, Beetroot, and others.

REMARKS.—The market is well supplied with Apples, including some fine samples of Bramley's Seedling, which are worth from 8s. to 10s. per bushel. Good dessert Pears, including a few fruits of Williams's Bon Chrétien, are meeting with a moderate demand. A consignment of Pearls arrived from the Cape this week; also Burbank and Wickson Plums. Grapes show no alteration either in supply or demand. Tenerife Tomatoes are a shorter supply. They are meeting with a steady demand at a advanced price. Vegetables have not sold so well this week. Trade in all branches is fairly good. E. H. R., Covent Garden, January 25, 1911.

DEBATING SOCIETIES.

GUILDFORD & DISTRICT GARDENERS.—The annual report and financial statement for the past year show that the association is in a satisfactory condition. Twenty-four meetings, including outings, have taken place, and much useful information has been gained from the various lectures. The annual flower show, which was held on July 18, resulted in a financial loss, but the deficit was made good to the society by some of the honorary members. The outings were very successful. The number of members is 165 as compared with 141 in 1909. The year's working shows a small balance in favour of the society.

CHELMSFORD & DISTRICT GARDENERS.—A meeting of the above society was held on Friday, January 20, at the County Laboratories, Chelmsford. The president occupied the chair. An address was delivered by Mr. N. Cumber, B.Sc., of the Chelmsford Laboratory staff on "Lime and its Uses." The lecture was divided under headings, including: (1) the nature and properties of lime; (2) forms of lime, (3) sources and uses of lime. Experiments were carried out during the lecture to illustrate certain properties of lime.

EGHAM (SURREY) GARDENERS.—At the meeting held on January 4, Mr. G. Baskett in the chair, Mr. W. Swan, Thorneate Gardens, Staines, gave a paper entitled: "Is the Flower Garden Desirable?" After speaking briefly of the flowers, fruits, and vegetables grown in the garden, the lecturer referred to some of the pleasures a well-kept garden afforded.

REMARKS.—Trade remains steady. Stocks in London are very large. *Edward J. Newborn, Covent Garden and St. Pancras, January 25, 1911.*

COVENT GARDEN FLOWER MARKET.

Large supplies of Daffodils and other flowers are arriving from France and the Scilly Islands. Narcissi are the chief flowers received from Scilly, and they are in good condition. Narcissi from France are also of good quality, but they are not so carefully packed; Soleil d'Or, Paper-white and Gloriosa are prominent varieties. Pheasant's Eye is also seen. Of the large trumpet Daffodils, Golden Spur, Van Sion (or *Telamionus plenus*), Henry Irving, and others are procurable. Tulips are in excess of the demand; some of the second early sorts are coming in, and these include double-flowered varieties. Supplies of Chrysanthemums hold out and are more than equal to the demand. Zonal Pelargonium Rospail is more plentiful. Flowers of best quality are in demand, there being few other good scarlet flowers available. Some growers send their flowers in very small bunches, and these are not worth so much as those of the usual size. Blooms of Azalea are well supplied and their prices are lower. Double White Primula is not so extensively grown as formerly. Roses are well supplied; the best red varieties, such as Liberty, being most in demand. Gardenias are making better prices. Camellias are plentiful and cheaper. Lily of the Valley varies but little, though supplies are large. Roman Hyacinth also is well supplied, and some imported flowers of the ordinary Hyacinth are seen. Imported Galax leaves may be added to the list of cut foliage. Good Maidenhair Fern is always scarce at this season, but there are plenty of small fronds. Asparagus plumosus of good quality is scarce. Other reasonable foliage is well supplied.

POT PLANTS.

Trade has been very quiet, and although supplies have not been large, they have exceeded the demand. Well-flowered plants of Indian Azaleas are procurable; Genistas are seen, but they are not so well flowered as later plants. Some good Chrysanthemums are observed, but there will be very few to follow these. *Frica hibernica* is one of the most useful water-flowering plants, and has been very good this season. Tulips are procurable in various colours, and are well developed. Narcissi also are good. Spruces are well flowered. Trade in Ferns and other foliage plants is very slow. *A. H., Covent Garden, January 25, 1911.*

ENQUIRIES AND REPLIES.

MITE AND RHUBARB.

IT is probably nice that are eating the crowns of *E. H.'s* Rhubarb (see p. 48). He should lay pieces of buttered bread about the ground for two or three nights and, if these are taken, apply Harley's Redne Rat Poison to the buttered bread on the fourth occasion. I have been troubled much the same way this winter, and have found this poison a sure and speedy remedy. *I. Johnson, The Lodge, Levens, Halton.*

ANSWERS TO CORRESPONDENTS.

ABNORMAL CROCUS: *W. A. H.* A similar case of abnormal, fleshy bracts in Crocus is described and illustrated in the issue for February 26, 1910, p. 133, fig. 59.

BEE-BUDS IN BLACK CURRANT: *H. S.* The shoots you send are infected by the bud mite (*Phytotritus ribes*). The mites live in the buds, feeding on the embryo leaves, and it is impossible to employ insecticides to kill them, as they are so effectively hidden in the tissues. The best plan is to pick off and burn all the diseased buds, or, if the bushes are badly affected, to destroy the entire plants. Select the variety Boskoop Giant for planting and make the new plantation in a different part of the garden. In May and June the mites migrate to new buds, and this is the time when spraying is effective. Spray at intervals of 10 days with a mixture of soft soap and quassia water, employing 2 ounces of soft soap and 4 ounces of quassia to each gallon of water. It is advisable to remove a portion of the surface soil under the bushes and replace it with fresh material.

Books: *Grey, Virginia, U.S.A., French Market Gardening*, by John Weathers, price 4s., and *A Diary and Manual of Intensive Cultivation*, by C. D. McKay, price 8d. These works can be obtained from our Publishing Department. The prices given include the postage to Virginia, U.S.A.

CARNATION EDITH WATERS. In referring to this variety in the note on novelties of 1910, the name Waters was incorrectly printed as Watts.

ECONOMY IN ANTHRACITE COAL AND COKE: *W. P.* Although there is a difference of 6s. per ton in the prices at which you can have Anthracite coal and coke delivered at your place, the question which fuel is the more economical to use in the Robin Hood and Saddle-back boilers must be determined by special circumstances. (1) If you only require to maintain a temperature of from 50° to 55° at night in your greenhouses during winter and early spring, coke will certainly be the cheaper kind of fuel to burn in the two furnaces. (2) But, on the contrary, if you use your glass-houses for the production of early crops of Cucumbers and Melons, or similar crops that need a temperature not lower than 65° to 70° in winter and spring, and you wish to bank your fires up at 10 o'clock at night and not to look at them again before 6 o'clock on the following morning, then large red-vein Anthracite must be used in the furnaces at night, and this will be found to possess the requisite heating power, and to be more economical. Coke can be used in the daytime, when the more frequent attention in stoking, which its use necessitates, is of no great consequence. Labour in stoking is greatly reduced by the use of Anthracite coal. By judicious stoking, Anthracite will maintain the water in the heating apparatus at boiling point for eight or nine hours after the furnace has been filled with fuel. You will need a good draught, and, therefore, a higher chimney stack than would be required for furnaces fed with coke only. The flue damper should be left about half way out of the aperture when the fires are made up for the night, in order to get the Anthracite to burn satisfactorily, whereas, if much space left in the flue would afford sufficient draught in making up the fires with coke. In using Anthracite coal, as large pieces as can be conveniently placed in the furnaces should be used, and then left to burn in their entirety; fresh lumps of coal should be added when necessary, but the fire should not be poked with the clinking bar each time fresh fuel is added, as is necessary when coke is being burnt.

GARDENER'S WAGES: *R. P. R.* You should bring the circumstance to the notice of your employer. It is no part of a messenger's duty to open communications addressed to others.

HYACINTH BULBS DISEASED: *S. D. de Son.* The bulbs show "yellow stripes," a bacterial disease, for which no cure is known. The soil in which they have been planted should be treated with quicklime.

MANCHESTER CORPORATIONS MANURE: *J. H.* The sewage of large towns is sometimes treated by what is known as the "Metropolitan System," in which lime and iron sulphate (copperas) are used to a certain extent. It is sent out in bags, in a dry, powder form, and is a useful manure for many crops. According to Griffiths, in his *Treatise on Manures*, a sample of "Manchester Concentrated Manure" was found on analysis to consist of the following:—Phosphates, 7.96 (containing soluble phosphates 1 per cent.); organic matter, 40.29 (containing ammonia, 3.69 per cent.); alkaline salts, 2.79 (containing potash, 0.79 per cent.); sulphate and carbonate of lime, 15.17; oxide of iron and alumina, 4.25; siliceous matter, 15.53; and moisture, 14.21.

MUSHROOM CULTURE: *W. G. S., Sidmouth.* You would fail to grow Mushrooms in ordinary loam. Mushrooms grow up upon organic matter for their supplies of nitrogen and carbon, as they cannot assimilate these materials like green plants. They draw their supplies from the remains of other plants, generally from straw, &c., present in manure. Therefore they would fail to grow in ordinary loam, unless humus were present in extraordinary quantities. In France especial care is taken in selecting the manure for the beds.

NAMES OF PLANTS: *A. H.* 1, *Helix* *S. hirolii*; we have never known this plant to produce its fruits in this country; 2, *Baptisus Sultanii*; 3, *Primula Forbesii*.—*A. G.* The labels were

detached. The moss-like plant is *Helix* *Soleirolii*; the one with variegated, grass-like foliage, *Chlorophytum elatum variegatum*; 3, *Ceropegia Woodii*.—*C. P. W.* Your plant is probably a dwarf Marjoram, *Origanum majorana*.—*C. L.* 1, *Cupressus sempervirens*; 2, *C. lusitanica*; 3, *C. pisifera squarrosa*; 4, *Tsuga Mertensiana*. The cause of the Laurel (*Cerasus Laurocerasus*) leaves being yellow may be due to one of several reasons, but which one can only be decided by those on the spot. The leaves of common Laurel growing in cold, heavy, or waterlogged soils, sometimes turn a yellow colour.—*Pious Strobus.* 1, *Cupressus Lawsoniana*; 2, *Juniperus Sabina*; 3, *Thuja occidentalis*; 4, *Juniperus* (the specimen is not sufficient to identify the species); 5, *Cedrus atlantica*.—*P. J. M.* 1, *Juniperus virginiana*; 2 and 3, *Cupressus nootkatensis*; 3, *Juniperus virginiana*; 4, *Thuja plicata (gigantea)*; 5, *T. occidentalis*; 6, *T. dolabrata variegata*; 7, *Juniperus virginiana*; 9, *Cryptomeria japonica*; 10, *Thuja dolabrata*.—*N. C.* 1, *Adiantum gracillimum*; 2, *A. Pacotii*; 3, *A. elegans*; 4, *Davallia Mooreana*; 5, *Gymnogramma cchiacea*; 6, *Cyperus laxus*.—*O. R. D.* 1, *Epidendrum elongatum*; 2, *Oncidium pulchellum*; 3, *Ionopsis paniculata*; 4, *Pleurothallis obovata*.—*S. L.* 1, *Pteris tremula*; 2, *Dracena terminalis*; 3, *D. pulcherrima*; 4, *D. fragrans*; 5, *D. congesta*; 6, *Reineckia carnea variegata*.—*Charley.* 1, *Cochlostema Jacobianum*; 2, *Campylobotrys regalis*; 3, *Sanchezia nobilis*; 4, *Codium (Croton) irregulare*; 5, *Begonia ricinifolia*; 6, *Cypripedium Murillo (Argus x Boxallii)*.—*C. W. T.* 1, *Asplenium bulbiferum*; 2, *Cyrtomium falcatum*; 3, *Pteris cretica albo-lineata*; 4, *P. argyrea*; 5, *Selaginella Mertensii*; 6, *Nephrolepis toledoides*.—*A. H. B.* *Leucodendron argenteum (Silver-leaf tree)*. The tree is a native of the Cape, where the leaves are employed extensively for ornamental purposes. An illustration of the seeds, showing their parachute-like character, was given in the issue for April 2, 1906, fig. 104.

ROSE LEAVES: *A. H.* There is no disease present. The appearance of the leaves suggests injury by scorching.

VANCOUVER ISLAND: *T. W.* According to *Land and Agriculture in British Columbia, Canada*, official Government Bulletin No. 10, issued by the Agent-General for British Columbia, the Island of Vancouver is adapted for the cultivation of almost all kinds of fruits, flowers, and vegetables that succeed in Great Britain. "The climate, mild and moist as in England, is warmer and brighter, with less average rainfall, the summers being invariably dry with continuous sunshine, while the winters are much less foggy, with frequent spells of crisp, bright weather. Holly, Ivy, Broom, Gorse, Box, Heather, Privet and other shrubs grow to perfection, and all the favourite English flowers are seen in the fields and gardens. Wallflowers, Primroses, and Violets bloom the year round, and in the early summer the whole country is transformed into a vast Rose garden, wild and cultivated varieties flourishing everywhere. . . . Along the eastern coast are several areas of open land occupied by successful farmers, fruit-growers, dairymen, and poultry raisers. Wheat is not generally grown, as mixed farming is found to be more profitable. Apples, Pears, Plums, Cherries, Prunes, and all kinds of small fruits grow luxuriantly, and Peaches, Nectarines, Apricots, Grapes, Almonds, Filberts, and other Nuts are produced with a little extra care and attention. Fig trees, found growing wild near Nanaimo, encourage the belief that this fruit can be successfully cultivated. Tomatoes, Melons, and other tender vegetables ripen well. Such is the fertility of the soil that a small patch of from 10 to 20 acres, well cultivated, will produce a handsome profit after supplying a comfortable living for an average sized family."

WINTER-FLOWERING SHRUBS.

THE chaste, white cups of the Christmas Rose, the beautiful and fragrant flowers of the Algerian Iris (*I. stylosa* or *unguicularis*), Iris *alata*, and other early species, cannot be too highly prized, but being borne by low-growing plants, far beneath the level of the eye, they do not form a feature in the landscape, such as is afforded by flowering shrubs.

Chimonanthus fragrans is a charming shrub, popularly known as the Winter Sweet, and in the south-west it is at its best at Christmas time, when its leafless shoots are thickly studded with exquisitely-perfumed, pale-yellow, maroon-centred blossoms. As a rule, it is trained to a wall, but, being a hardy plant, such protection is unnecessary, and on a wall it has no decorative value, whereas, if it is grown as a shrub and backed by evergreens, it is a pleasing feature in the garden. In Devonshire, a specimen has grown into a bushy shrub about 15 feet in height, with a like diameter, and when in full flower it spreads its fragrance far. It must be hard pruned if trained to a wall; but when grown as a shrub it requires no pruning. A variety known as *C. f. grandiflora* bears larger but less sweetly-scented flowers than the type.

Lonicera fragrantissima is admirably

named, for its clusters of small, white flowers, borne at the axils of the shoots, are deliciously scented. In a sunny, sheltered nook it will bloom in January. It is a bush species, and its flowers withstand several degrees of frost without injury. Although it is perfectly hardy, the species is useful under glass, where it will bloom a month earlier than in the open air, and a large plant will fill a conservatory with perfume during the dark days of December. It is classed as an evergreen, but when exposed to severe frost and cold winds it often loses many of its leaves. It is a native of China. *L. Standishii* is a very similar species.

Cornus Mas, known as the Cornelian Cherry, commences to bloom in February, and is a pretty sight when covered with flowers in the early days of March. The individual blossoms are not particularly showy, being composed of narrow, yellow petals, radiating in a circle, like the spokes of a diminutive wheel; but when each spray is thickly studded throughout its entire length with flowers, the shrub presents a decidedly attractive appearance.

Daphne Mezereum is not a particularly graceful shrub, but is well worthy of a place in the garden on account of its purplish-pink or pure white, scented blossoms, which cluster thickly round its stiff, upright shoots, when they are bare of leaves in winter. It often commences to flower as early as December. There is a larger-flowered form, known by the name of *D. M. grandiflora*, which is superior to the type. *Daphne indica*, which is held at Kew to be identical with *D. odora*, is considered tender, and is generally given a place in the greenhouse. It is, however, far hardier than is usually supposed, and, in sheltered positions in the south-west, succeeds admirably out-of-doors, often flowering as early as January, when it scents the air with its rich perfume. There are three varieties, which have, respectively, reddish-purple, white with a red reverse, and pure white flowers.

Erica lusitanica, better known as *E. colomades*, is a fine, tall-growing Heath, often attaining a height of 8 feet or more. In mild winters it commences to perfect its pinkish-white blossoms as early as January, and becomes an object of increasing beauty as the days lengthen, when it is a cloud of flower. It propagates itself readily by self-sown seedlings.

Hamamelis arborea, a very attractive member of the Witch Hazel family, blossoms on its leafless branches in mid-winter. Its flowers, before they expand, look like rolls of narrow, yellow ribbon, and when fully open they have the appearance of strips of gold-leaf. A freely-flowered specimen presents a bright picture, especially when the flowers are thrown into high relief by a background of Yew or other dark-leaved evergreen. The blossoms will remain uninjured even in 10 or 15 degrees of frost.

Prunus Davidiana is the earliest-flowering of the Almonds, and, in favoured districts, often commences its season of bloom in January. The type bears rose-coloured flowers, and is a beautiful sight when in blossom, but still more lovely is the pure white variety, whose snowy blossoms are just as freely produced, and are extremely charming on the slender sprays. The white variety is generally

of better form and more free-flowering than the rose-coloured, and, when grown in a sheltered spot, backed by evergreen foliage (as all leafless, winter-flowering shrubs should be), it presents a delightful picture.

Garrya elliptica is a handsome, catkin-bearing shrub that should have a place in every garden. Though a native of California, it is practically hardy, and is well grown in Scotland. In the winter, when covered with countless drooping catkins, some of which exceed 12 inches in length, it is a particularly striking object, especially in an open position on the lawn. It is seen at its best in Cornwall, where huge bushes, 15 feet or more in height, and as much in diameter, may often be seen crowded with hanging catkins.

Arbutus Unedo, sometimes known as the Strawberry Tree, on account of its bright red fruit, is very ornamental in the winter when bearing its small, white, bell-shaped blossoms and glowing fruit. There are many species, *A. canariensis* being a very handsome one, and quite hardy in the south-west.

Nuttallia cerasiformis is a native of California, but may be considered fairly hardy, as it succeeds at Kew when totally unprotected. In March, and sometimes earlier, the clusters of small, white, drooping flowers are produced slightly in advance of the leaves. The blossoms have a pleasing, but not powerful fragrance.

Viburnum Tinus, the well-known Laurustinus, is too common to need more than a passing mention, but an exceptionally fine variety is *V. T. lucidum*, which bears flower-trusses of snowy-whiteness and far larger than the type.

Jasminum nudiflorum, though not strictly a shrub, can scarcely be omitted from this list, as the sheet of clear yellow which is formed by its countless, starry blossoms forms one of the most beautiful features in the winter landscape, and is especially charming when associated with *Cotoneaster microphylla* on a house-wall, the crimson berries of the latter forming an excellent contrast to the yellow flowers of the Jasmine. *Wyndham Fitzherbert*.

THE ALPINE GARDEN.

SAXIFRAGA LINGULATA AND S. LANTOSCANA.

I HAVE every personal esteem for M. Correyon, but this shall never lead me into following him with the unquestioning faith of some writers. Error there clearly has been, and is; our only concern is to admit it and to put it right. So here is Boissier's own description of *Saxifraga lingulata* B. lantoscana (Engler and Burdet: *S. lantoscana* of Boissier) faithfully translated from the Latin. He says "it is near *S. lingulata* of the Tenda valleys, differing in a less grey-green colouring, verging more to brown (brunneum: colour words in a dead language are proverbially difficult: I myself should describe the very characteristic difference as consisting in a stronger admixture of ochre) leaves more often convex at their end, not furrowed, as in *lingulata*, much less lengthily attenuate towards their base, not drawn out to a point at their tip, seldom and bluntly acute, with a thinner marginal band (of chalk), which is less conspicuous, owing to the convexity of the upper surface." Now, try to apply this to M. Correyon's Aizooid plant, which is absolutely unlike "*lingulata*" of the Tenda valleys in every one of its parts. But that is Boissier's description

of his own *lantoscana*, the plant of the Vésubie valley. As for "modification by culture": for 10 years I have grown quantities of Boissier's *lantoscana*, collected in the Vésubie valley, and never, naturally, have they "modified" their leaf or spike in the least degree. What amount of "modification by culture" will turn one species into another—an *Aizoon* into a white-flowered *lingulata*? If culture will produce these happy effects, let us all grow myriads of plants of *Aizoon*, in the hope that we may some day see them "modified" into *florulenta*. No; Boissier's description only fits the real Vésubie *lantoscana*, and all other versions must be changelings or hybrids. In no case do they answer Boissier's picture of the species supposed to be named from them. Why, the edge of the leaves, and their shape, show at a glance that they have no sort of relationship with any *lingulata*. While the totally different and perennially "unmodified" *lantoscana* of the Vésubie obviously is a relation of the Tenda plant, and a very close one, too. And, finally, if we are to go to authorities, let us go at once to the best; the best authority on the Maritime Alps is not Correvon, nor Boissier, but Burnat, whose whole account of *Saxifraga lingulata* I now propose to give, as a definite and final settlement, with one last word for Prof. Arbois's note. He says *Saxifraga lantoscana* "loves dry and hot places." This may be; if so, the poor plant has but a thwarted life, for it never, by any possibility, occurs in healthy character, except on cool, damp, and shady ones. Now for Burnat's "*lingulata*." Briefly, there is no such thing. As I understand it, he postulates "*Saxifraga lingulata*" as a sort of mythical archetype, not to be found or fixed on earth.* Of this myth, then, there are held to be two parallel developments: the one is called *S. lingulata* A Bellardii (of Sternberg). This is the Saxifrage of the Tenda valleys, which, with all due respect for Prof. Arbois, does not occur in "wet" places, but has a faint preference for the shadier side of cliffs. The other variety of "*lingulata*" is *S. lingulata* B *lantoscana* (of Engler; Boissier's *S. lantoscana*). This is the Vésubie Saxifrage, which has no affinity at all with any *Aizoid* form. The distribution of these two subspecies is very elaborately made out by Burnat: there is no room for any confusion as to the Vésubie Saxifrage. Then there are also, round Tenda, and elsewhere in that district, a number of intermediates and missing links between A and B. But *lingulata* species, I repeat, has no separate existence: *Saxifraga lingulata* of Ardoino is included in *S. lingulata* Bellardii of Sternberg. Therefore I would very strongly urge that, for the sake of simplicity and correctness, gardeners should in future know these Saxifrages as *S. Bellardii* and *S. lantoscana* respectively. The Tenda plant has no right to a monopoly of the name *lingulata*: to accord it is to put an unjustified slight on *lantoscana*, which is not its variety, but a co-equal divergence from a vanished (or mythical) type. We have had the description by Boissier of B *lantoscana* (the real one). Burnat endorses it, but agrees with me in noting no substantial difference as to the silver margin (I should even say that in B the margin is more often a broad regular hem). With regard to the relationship, at which I have guessed, between "*lingulata*" and *cochlearis*, Burnat has some interesting remarks. The relationship was actually claimed by Engler; and Burnat is so far from denying it that he merely declares himself unable to confirm it, because he himself has never yet met any intermediates. It is possible, however, that the connection of *cochlearis* and A Bellardii is, as I had thought, through B *lantoscana*. At least, there is a botanical indication: in *cochlearis* the stems and calyxes are invariably more or less glandular; in *lingulata* B *lantoscana* glands are found in about 33 per cent. of specimens examined: they are very rarely as abundant as in *cochlearis*—a few are seen on the

calyx, and fewer on the lower stem; in the intermediates between A and B, of all the specimens examined, only three yielded glands, and those only on the calyx, while *Saxifraga lingulata* A Bellardii is never glandular at all in any of its parts. With regard to *Saxifraga florulenta*: this plant was discovered by Molinari about 1820; fully described, named, and figured by Moretti in 1824; took its due place in 1872 in Engler's pages (after its rediscovery by a nameless English tourist in 1840), and is referred to by Maw in the *Gardeners' Chronicle*, 1874. That is to say, it was a species as distinct and conspicuous as the Matterhorn among mountains. Will someone explain, then, how it was ever possible that so outstanding a species should have found its way into the Kew *Hand List* as

NEW OR NOTEWORTHY PLANTS.

A NEW GENUS OF CONIFERÆ.

IN 1908 Mr. S. T. Dunn described, as a new species of *Cupressus*, a tree growing near Foochow, in eastern China, which had been discovered by Capt. Hodgins, of the s.s. "Haiching." In March, 1909, Capt. Hodgins procured further dried material and four living plants for Capt. L. Clinton-Baker, R.N., who sent these to his brother, Mr. H. Clinton-Baker, whose pinetum at Bayfordbury is well known for its rare and beautiful specimens of conifers. During Capt. L. Clinton-Baker's stay on the Eastern

FIG. 32.—*FOKIENIA HODGINSII*: A NEW GENUS OF CONIFERÆ.

a mere variety—of *S. lingulata*? If the plant was sufficiently known to be reckoned with at all, how was the compiler able to evade the knowledge that it was a monocarpous, red-flowered, green-leaved, three-styled, silicicole species—that is to say, as far removed as any *Saxifraga* could be, both botanically and geographically, from all forms of *Saxifraga lingulata*, which is perpetual, normal, white-flowered, chalk-frilled, and calcicole? Could the compiler of the Kew *Hand List* have based his record, by any chance, on a "*Saxifraga florulenta*" shown years since at a meeting of the Royal Horticultural Society? And could that *florulenta* have been some ambitious cousin of Bellardii? But into these doubtful questions I will not plunge: it was all long before my time. *Reginald Farrer.*

station, he occupied his leisure in the search for new and remarkable conifers in China, Formosa, and Japan: and to him must be given the credit of the introduction of several species, such as the tree under review, *Pseudotsuga japonica*, and *Cupressus formosensis*, the latter being the largest tree known in the Far East, one giant* on Mt. Morrison, in Formosa, being 67 feet in girth.

With the assistance of Mr. H. Hamshaw Thomas, M.A., of Cambridge, I have carefully examined the material kindly given by Mr. H. Clinton-Baker; and we have come to the conclusion that this tree from the Fokien province must be made the type of a new genus, which

* Cf. Elwes and Henty, *Trees of Great Britain*, v., 1, 150 (1910).

we now publish as *Fokienia*.† A. Henry and H. H. Thomas. It is intermediate in its characters between *Cupressus* and *Libocedrus*, and may be briefly characterised as an evergreen tree, belonging to the Cupressineæ, with cones similar to those of *Cupressus* (section *Chamaecyparis*), in being globose in form, and composed of numerous peltate scales, but with each scale bearing two seeds which are like those of *Libocedrus* in having two very unequal lateral wings; while the foliage is nearly identical with that prevalent in the Chinese and North

scribed in detail as follows:—A tree attaining 40 feet in height and 3 feet in girth, glabrous in all its parts. Foliage in flattened "branchlet-systems," each leaf-bearing branch tripinnately divided, all the pinnae being disposed in one plane. Leaves in four ranks, the lateral pair in each rank being different from the facial pair (the dorsal and ventral leaves); resembling those of *Libocedrus macrolepis* in general appearance and also in being markedly different on young and old trees.

On young plants the leaves are considerably

facial pair, and separable from these at their inner margin; while in *Fokienia Hodginsii* the lateral leaves are flat and not conduplicate, and merge by their inner margins into the facial leaves.

In adult trees the leaves on the ultimate branchlets are similar to those of *Libocedrus macrolepis*, arising in whorls of four at the same level; the lateral and facial pairs approximately equal in length, about $\frac{1}{2}$ inch; all acute or slightly obtuse and not acuminate at the apex; lateral leaves conduplicate, and embracing the facial leaves, with white stomatic depressions on their ventral surfaces; facial leaves oblanceolate with a broad triangular apex. On older branchlets the internodes elongate, and the

American representatives of the last-named genus.

Fokienia Hodginsii, A. Henry and H. H. Thomas, the only species known, may be de-

† *FOKIENIA*, A. Henry et H. H. Thomas, genus novum Cupressinearum, inter *Libocedrum* et *Cupressum* collocandum; strobili globosi, squamæ peltatæ, quam in *Cupresso* § *Chamaecyparide*, sed dispermæ; semina bialata, alis lateralibus valde inæqualibus, quam in *Libocedro*; folia et habitus *Libocedri macrolepidis*. Species unica, *Fokienia Hodginsii*, A. Henry et H. H. Thomas, arbor, 40 ped. alta, in prov. Fokien Chinae orientalis.

Cupressus (§ *Chamaecyparis*) *Hodginsii*, Dunn, in *Journ. Linn. Soc. (Bot.)*, xxxviii, 367 (1908); Henry, in *Elwes et Henry, Trees of Great Britain*, v., 1, 150 (1910).

larger than in the adult stage, averaging $\frac{1}{3}$ inch long, all ending in spine-like points; lateral leaves triangular, flat, longer than the adjoining facial leaves, with which they are connate, green on the upper surface, marked on the lower surface with a conspicuously white longitudinal stomatic area; facial leaves oblanceolate, shorter and much narrower than the lateral leaves; the ventral leaf with a raised midrib, on each side of which is a narrow stomatic band. In the young foliage of *Libocedrus macrolepis* the lateral leaves are plainly conduplicate, embracing the

FIG. 34.—*LIBOCEDRUS MACROLEPIS*.
K, Juvenile foliage; L, Adult foliage; M, Main axis.

leaves arise at different levels on the axes in opposite decussate pairs; the lateral pair oblong, with the triangular apex spreading outwards and tipped with an incurved point; the facial pair similar, but with the apex appressed. In *Libocedrus macrolepis*, the arrangement on the main axes or older branchlets is quite different, the oblong leaves arising in whorls of four at the same level.

We have seen no staminate flowers. Young female cones, terminal, composed of six to eight pairs of opposite, decussate, blunt-pointed, rounded scales; ovules, two on each scale, flask-

FIG. 35.—*CUPRESSUS LAWSONIANA*.
N, Scale of young cone, showing ovules; O, Ripe cone.

shaped, smooth and rounded, with a large micropyle. Mature cones, ripe in the second year, on short scaly stalks (about $\frac{1}{8}$ inch long), globose, when open about 1 inch long and $\frac{7}{8}$ inch wide; scales, 12 to 16, woody, peltate, clavate or cuneate in shape, expanded externally into a wrinkled oblong apophysis, which is deeply concave, with radial striations on the sides of and a ligulate micro in the centre of the depression. Seeds, two on each fertile scale, about $\frac{1}{8}$ inch long, triquetrous or tetrahedral, pointed at the distal end, flattened at the base, which is marked by an oval hilum; two large resin-vesicles underneath the seed coat on the upper and lower surfaces; wings lateral, very unequal in size;

† The inequality of the wings depends on the amount of room available on the scale of the cone. The larger wing rests on the outer side of the scale, the lesser wing on the inner side. The latter is best developed on the large middle scales of the cone.

the larger wing attached to the whole length of one side of the seed ($\frac{1}{2}$ inch), trapezoidal, oblique with a short anterior and a long posterior margin, the upper edge rounded or truncate and about $\frac{1}{4}$ inch; lesser wing variable, occasionally rudimentary, usually attached to the anterior part only of the other side of the seed, short, narrow at its upper end, which is about $\frac{1}{2}$ inch broad.

We have pointed out above the great similarity of the foliage of *Fokienia Hodginsii* to that of *Libocedrus macrolepis*, a native of south-western China and Formosa; but there is no difficulty, as we have shown, in distinguishing the two plants either in the young or the adult stage. The cones are similar in shape to those of certain *Cypresses* of the section *Chamaecyparis*, as *Cupressus Lawsoniana*, but are larger and take two years to ripen. Moreover, in the *Lawson Cypress*, the ovules are usually three on each scale, and are very different in shape, being flattened, with a slight wing-like expansion on each side. The seeds furnish, however, the most important character, and are totally different from those of any species of *Cupressus*. In the latter genus, the wings, though two and lateral, are very narrow and equal, and surround nearly the whole of the seed; and according to Mr. Thomas, appear to be present in the ovules in a rudimentary condition. In *Fokienia* the wings are lateral and very unequal, and appear to be derived from the scale of the cone, as no trace of them is visible in the ovule. The structure of the seed, of *Libocedrus* appears to be identical with that of *Fokienia*, the only difference perhaps being that the lesser wing is usually little developed in *Libocedrus*.

According to Capt. Hodgins this tree is rare, and occurs in the province of Fokien, in the Yung-fu district (N. lat. 26°, E. long 119° 15') at a few hundred feet above sea-level on the northern slope of one valley, about 20 miles from the sea. Here he found three clumps, containing altogether about 18 mature trees. In the same district *Cunninghamia sinensis* and *Keteleeria Fortunei* are cultivated for their timber; and, judging from this, the new conifer ought to succeed in the south-western counties of England, and in parts of Ireland and Wales where the climate is mild. Higher up on the mountains of Fokien, about 2,000 feet, Capt. Hodgins found *Cryptomeria japonica* apparently wild.

Mr. Dunn also found small trees of this species, without flowers or fruit, in woods near Yenping in the interior of the same province at 2,000 feet, and introduced it (by young plants collected by Mr. Hodgins) into cultivation in the botanic garden at Hong Kong. In the Kew Herbarium there is also a branch of this species labelled "Amoy, China, from H. F. Rankin, Sept. 18, 1908"; and in all probability the tree is widely distributed through the interior of Fokien, which has scarcely been explored by European botanists.

The figures are reproduced from drawings made by Mr. Thomas. *Aug. Henry.*

THE ROSARY.

CULTURAL NOTES FOR FEBRUARY.

Cut back all budded stocks, whether dwarf or standards, before the sap is active; advantage should be taken of the first favourable weather to carry out this work, but much treading on the ground whilst it is wet should be avoided. The shoots of dwarf stocks may be cut back to within 1 inch of the buds, but I do not recommend cutting so closely in the case of buds on standard briars. A sharp knife is much the best implement to use, being superior to any form of secateur; for a knife leaves a clean cut, whereas the

other implement bruises the shoots more or less. Opportunity should be taken at the same time to trim the stems of the standards. The present is an excellent time to apply mulchings. The roots will shortly become active, and be able to appropriate the manurial constituents of the mulching, whereas in the case of autumn mulches much of the fertilising value is lost through the winter rains. As no further trimming will be necessary after this pruning, the ground may be dug, but often very superficially, so as not to disturb the roots; the object being to disturb the soil just a little more deeply than could be done with the hoe.

PRUNING.

It is too early to commence the pruning of *Roses* generally, but such hardy sorts as the *Moss*, *Provence*, and most *Briar Roses*, may be pruned towards the end of February, if for one reason or another it is convenient to perform the operation then. Cut the longest shoots back about half their length, but prune the weaker ones more severely. All these *Roses* need a rich soil, yet they are too often planted in some neglected part of the garden, where the soil and other conditions are unfavourable.

PLANTING STOCKS.

Briar stocks to be grown as standards should be planted during the late autumn, but those intended for dwarf plants may be planted at the end of the present month. The best plan is to put them in rows, and not, as is sometimes done, directly into their permanent positions. Those intended for dwarfs may be placed 9 inches apart in rows made 2 feet distant; but in the case of varieties of extra-vigorous habit, allow them a foot apart in the row and 3 feet between the rows. Endeavour to plant dwarf stocks as shallowly as possible, just covering the roots with soil and drawing a little about the stems, partly to help to support the plants in the ground, and partly to protect the roots and stems from drying winds. The benefit of shallow planting and earthing up will be found at the budding season.

Roses growing in warm borders frequently start into growth by the end of February; this must not be taken as a hint to commence pruning, which should not be started until the first week in March, even in the case of very hardy varieties. As a rule there are plenty of dormant eyes below the buds which push prematurely into growth, and they will furnish the plant with new shoots, but if the top growth is cut away early in the year, the lower buds are forced into growth, only to be injured by frosts in spring.

ROSES UNDER GLASS.

The winter-grafted *Roses* will need great care, and must be shaded during periods of bright sunshine, otherwise they are liable to be damaged by scorching. A few pieces of brown paper will serve admirably for shading material. A gentle spraying with clear water will prove beneficial during bright weather, and will help to prevent excessive warmth during bursts of sunshine. This applies also to *Roses* under glass grown for early blooming; short spells of sunshine cause the temperature of the house to rise rapidly at a time when it is not safe to open the ventilators, and a gentle spraying with the syringe, accompanied by a sprinkling of water over the paths, walls, and other bare spaces will cause a lowering of the temperature through evaporation of the moisture. At the same time, be careful not to use sufficient moisture to cause the foliage to be damp next morning, for this would militate against the proper opening of the blossoms, and probably cause some of the points of the shoots to damp off.

Insect pests will become troublesome from now onward. The most effectual remedy is to fumi-

gate the house overnight, and syringe the plants with clear water on the following morning.

Plants in pots will be benefited if they are turned round occasionally so as to change their positions in regard to the light. At the same time stir the surface soil in the pots very lightly. Climbers and other *Roses* planted in houses sometimes produce roots that find their way into borders outside the house. In all cases where roots are growing in outside borders, the soil should be covered with a layer of light, strawy manure or litter, as a protection from the cold. Inside borders often appear moist on the surface, whilst they are dry underneath. It must be remembered that the rain does not reach them, therefore their condition with regard to moisture should be ascertained at intervals, for drought is very injurious.

Now is the best time to pot up a batch of *Roses* from plants growing in the open; keep the pots half plunged beneath the soil in a cool situation. These plants will be valuable for forcing during next season. It will be well to pot a good number so as to allow plenty of choice; the surplus plants will serve to fill blanks in the beds and borders out-of-doors and to replace any that have proved unsatisfactory. Newly-planted *Roses* should be pruned rather hard at the time of planting, for, as a result of hard pruning, the roots have fewer shoots to supply with nourishment. *A. Piper.*

VEGETABLES.

MÂCHE OR LAMB'S LETTUCE.

UNDER the name "Mâche" the London West-End greengrocers have found a ready sale for tufts of the salad plant known to English gardeners either as *Lamb's Lettuce*, corn salad, or white potherb. *Mâche* is the French name for this salad, and as most of the Christmas supplies come from France, no doubt many people who bought it were under the impression that they were obtaining a rare delicacy. It must be admitted that the French market growers show a greater knowledge of human nature and display more enterprise than do the majority of our trade cultivators. For it is at such times as Christmas and Easter that people indulge in luxuries, and many comestibles then sell freely, though they have little or no steady sale. There are two desirable forms of corn salad, the common or round (*Valerianella olitoria*) and the Italian (*V. erio-carpa*). Their chief value is for use during the winter months as a substitute for Lettuce. Except as an occasional novelty, one cannot conceive a demand for *Mâche Lettuce*, for as a raw salad its growths are not very palatable, though when dressed with the usual condiments, they are, to many palates, delicious. The whole plant—which, at a glance, has much the appearance of a tuft of *Forget-me-not*—is used, and is rarely blanched, but is served in the green state. The chief sowing should be made towards the middle of August, to be followed by small successional sowings until the end of October. This practice will furnish plants for the period at which they are likely to be in request, although, where required, the *Lamb's Lettuce* may be had all the year round. Almost any garden soil will successfully grow this salad plant, but it should not be freshly manured, and a dry and moderately open position should be selected. The seed should be sown shallowly in drills drawn 6 inches apart, and at the final thinning the plants should be left a similar distance from each other. The thinnings will be useful for mixed salads. Although the original round corn salad is a native plant, some slight protection is needed during severe frosts. *J. C. Bartlett.*

|| Resin-vesicles occur on the seed of *Libocedrus* and *Fokienia*, and are present in certain species of the section *Chamaecyparis*.

HYBRIDS RAISED AT KEW.*

(Concluded from p. 36.)

Rhododendron (*R. intricatum* × *R. indicum album*).—The cross was made in 1903 and seedlings raised in 1909, but the plants have not yet flowered.

Rhododendron (*R. Smirnowii* × named garden varieties).—A large number of hybrids was obtained from crosses made in 1893 and 1894, most of which were of very vigorous growth but inferior to the majority of garden varieties in their flowers. A few, such as those named "G. Thiselton-Dyer" and "Mrs. Prain," were of average merit. Hybrids from *R. Smirnowii* are likely to prove quite hardy.

Rhododendron *Edith A. Boulton* (*R. Fortunei* × *R. Meteor*).—This hybrid, produced in 1894, has proved to be one of the best of the *Fortunei* race of *Rhododendrons*—a race of considerable value in gardens, because they flower somewhat in advance of the better known hybrids and thereby lengthen the flowering season of the genus. It is curious in producing many flowers without stamens.

Rhododendron (*R. Vaseyi* × *R. cinnabarium*).—Cross made in 1897. The hybrid is a curious-looking small-leaved shrub which has not yet flowered.

Rosa (*R. macrophylla* × *R. rugosa*).—It is impossible to obtain *Roses* true from seed gathered from the plants growing together in the collection, because of the cross fertilisation caused by bees. The result is nearly always a worthless mongrel, and the propagation of *Roses* by seed from this source is no longer attempted. Amongst the hybrids formerly so raised, however, is a very handsome unnamed one with the parentage given above. Its beauty is in its fruits, which are Pear-shaped, as in *R. macrophylla*, but larger and of a brilliant scarlet-red. Miss E. Willmott is figuring this hybrid in her new work on the genus *Rosa*.

Senecio kewensis (*S. [Cineraria] cruenta* × greenhouse *Cinerarias*).—In 1833 Kew introduced and flowered *Senecio (Cineraria) cruenta*, believed to be the progenitor of the popular race of greenhouse *Cinerarias*. It was afterwards crossed with the latter, and the seedlings thus obtained were known as *Kew Cinerarias*. Plants and seeds were distributed from Kew, and shortly afterwards a selection from them was shown by Messrs. Sutton & Sons under the name of *C. stellata*. Some of the Kew seedlings came fairly true from seeds and were known as "Kew Blue," "Kew White," &c.

Senecio Lady Thiselton-Dyer (*S. Heritieri* × *Cineraria Kew Blue*).—The cross was made in 1899. The plant has the shrubby habit of *S.*

No. 2, 1910, p. 65. It is remarkable for its large leaves, which have blades 2 feet long and 15 inches wide. The flowers are pale ochre-yellow and blue. (See *Gardeners' Chronicle*, 1910, xlvii., 217, with figure.)

Strelitzia (*S. augusta* × *S. Regina*).—Several plants were obtained from the cross made in March, 1893, but as yet no flowers have appeared.

Streptocarpus Watsonii (*S. parviflora* × *S. Dunnii*).—Cross made in 1836, flowered in 1837. The plant is monophyllous. Inflorescences numerous, produced in succession along the base of the midrib of the large single leaf. Flowers numerous, mauve-purple in colour shading to brownish-purple in the throat, 2 inches long, 1½ inch broad. Plant dies after flowering, producing no seed. (See *Gardeners' Chronicle*, 1837, ii., 214, fig. 52.)

Streptocarpus kewensis (*S. Rexii* × *S. Dunnii*).—Cross made in 1836, seedlings flowered in 1837. Habit as in *S. Rexii*; that is, it forms several leaves to each plant. Flower stems numerous, 3-8 flowered, bearing a compact mass of flowers as in *S. Dunnii*. Flowers mauve-purple, with brownish-purple marking in the throat. (See *Gardeners' Chronicle*, 1837, ii., 246, fig. 61.)

Streptocarpus White Pet (*S. Rexii* × *S. parviflora*).—Cross made in 1836, plants flowered in 1837. Habit as in *S. Rexii*; leaves two or more, 5-7 inches long, 2-3 inches broad. Inflorescence 4-6 inches high, bearing 2-5 flowers.

Streptocarpus Dyeri (*S. Dunnii* × *S. Wendlandii*).—Cross made in 1892, plants flowered in 1894-95. Plant monophyllous; leaf 2-3 feet long and 16-18 inches broad. Inflorescence an erect, many flowered cyme, 12-30 inches high; flowers reddish purple. Figured in *Garden and Forest*, 1895, fig. 1. For further particulars of the Kew hybrid *Streptocarpus*, see *Gardeners' Chronicle*, 1890, viii., 410.

FAILURES.

- Hippocastanum* × *Vallota purpurea*.
 - Hippocastanum* × *Clivia miniata*.
 - Impatiens Oliveri* × *I. Sultanii*.
 - I. Oliveri* × *I. Herzogii*.
 - Mecynopsis aculeata* × *M. heterophylla*. Seeds from this cross ripened and appeared to be good, but did not germinate.
 - Oxalis enneaphylla* × *O. adenophylla*.
 - Primula kewensis* × *P. floribunda*.
 - P. malacoides* × *P. obovata*.
 - P. megacalydia* × *P. obovata*.
 - P. obovata* × *P. sinensis*.
 - P. sinensis* × *P. verticillata*.
 - P. sinensis* × *P. vulgaris*.
- In nearly every case the reverse cross was also made. Among shrubs, failures have been experienced with *Hypericums* and *Ericas*, not due, however, to any inherent incapability of hybridization in these genera, but to accident or defective fertilisation.

FIG. 36.—LAGENOPHORA FORSTERI IN THE ROCKERY, ROYAL BOTANICAL GARDENS, EDINBURGH.

Rhododendron (*R. campylocarpum* × *R. Esmeralda*).—One of the most desirable things in regard to the cultivation of *Rhododendrons* is the production of a race with good yellow flowers. It was thought that something in this way might be done by crossing these two, the former of which is pale yellow, the latter light red. About 25 hybrids were obtained from this cross made in 1897, only one of which has yet flowered, and this was as pale a yellow as the mother plant.

Rhododendron (*R. Griffithianum* × *R. campylocarpum*).—The hybrid, produced in 1898, bears cream-coloured flowers, but is not of striking merit.

Rhododendron Griffithianum ? was also crossed with various garden varieties. The best of the hybrids obtained were those from flowers pollinated with "Grand Arab" and "Ascot Brilliant." The trusses are red. The plants are only half-hardy at Kew.

Rhododendron (*R. ciliatum* × *R. Edgeworthii*).—The hybrid, obtained in 1900, is of interest in being exactly similar to the variety called "Princess Alice," a well-known greenhouse plant.

Heritieri, and the blue and white flowers also show the ringed markings of the seed parent *S. Heritieri*. A plant was exhibited at the Royal Horticultural Society's meeting of April 23, 1900. (See *Gardeners' Chronicle*, 1900, xlvii., p. 3 of supplement.)

Shortia (*S. uniflora grandiflora* × *S. galacifolia*).—Cross made in 1910. The seeds were sown as soon as they were ripe and germinated in a short time, but the plants have not yet flowered. Flowers of *S. galacifolia* fertilised with pollen of *S. uniflora grandiflora* did not produce mature seed.

Spathoglottis kewensis (*S. plicata* var. *Micholitzii* × *S. Vieillardii*).—This hybrid, produced in 1900, flowered in 1903. The colour of the flowers mostly resembles that of the female, being bright reddish-purple, 2 inches in diameter, with the pale yellow markings on the lip and column which are characteristic of *S. plicata* var. *Micholitzii*.

Strelitzia kewense (*S. Regina* × *S. augusta*).—Several plants were raised from the cross, made in March, 1893, one of which is growing in the Mexican House at Kew. This one flowered for the first time during the winter 1909-1910, and was described as *S. kewense* in the *Kew Bulletin*,

LAGENOPHORA FORSTERI.

LET me commend to the notice of lovers of carpet rockery the species *Lagenophora Forsteri*, illustrated in fig. 36, from a photograph of a plant growing in the Rock Garden of the Royal Botanic Garden, Edinburgh. To the European in New Zealand the plant is "Native Daisy," a name which indicates well its growth-form in summer, and one which is likely to be more acceptable in gardens than "Papataniwhaniwha," by which it is known to the native in New Zealand. Like many other scape-flowering Composites, *Lagenophora Forsteri* is a rosette plant, but the rosette is looser and fewer-leaved than is that of our common Daisy, and the obovate leaves have narrower petioles and toothed blade. They die off in winter. There is no yellow eye to the head. Though wanting in this colour contrast of our common daisy, the New Zealand Native Daisy merits equally the title "crimson tipped," only it is the involucrel bracts which have red tips, the ray florets are always pure white. Easily grown, increasing rapidly by offsets, and quite hardy, this charming little plant should be generally known. I. B. B.

* Reproduced from *Kew Bulletin*, No. 9.

The Week's Work.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

MELONS.—The structure chosen for the earliest crops of Melons should be one where plenty of both top and bottom heat is at command. The house should be well cleansed before the bed is made up, and the bed should be made very firm, to promote a sturdy growth. Where there is sufficient bottom heat, no assistance will be required from a hot-bed. Some growers prefer to plant in a small quantity of soil and then add quantities of loam as the growth advances, but I prefer to make the entire bed at once, using good turfy loam and a good sprinkling of soot, wood ashes, lime or old mortar rubble, and road or river sand. Ram well as the work proceeds, finishing off with a perfectly level surface, then with the finest of the soil make a small hillock in which to plant the varieties in the position they are to occupy. After planting, place a neat bamboo or stick and secure this to the first wire of the trellis for training the young plant. Spray the young plants with tepid water when the weather is bright, and frequently damp the surroundings, repeating this in the evening if the paths or walls become dry. Maintain a temperature of 65° to 70° at night, according to the conditions out-of-doors. Prevent cold draughts, using the outer doors as little as possible, and in the event of very cold weather protect the glass by an outside covering, which is much to be preferred to the use of excessive firing.

CHERRIES.—Cherry trees, whether grown in pots or borders, must not be forced quickly into growth, as they cannot stand hard forcing. Neither can Cherries stand severe pruning, for this produces gumming. Therefore, when the trees are in active growth, pinch and thin out the shoots to assist in the formation of fruit buds at the base. Admit plenty of air to the houses and start the trees gradually. Those in pots which have been plunged out-of-doors should have the pots thoroughly cleansed and the drainage made perfect. If the plants were not potted last autumn, carefully remove the old surface soil with a pointed stick and give them a good top-dressing consisting of a compost of good, turfy loam, with a sprinkling of wood ashes, soot, bonemeal and lime rubble. Stand the pots perfectly level, and if placed on the borders rest them on something firm to prevent worms gaining access to the soil.

STRAWBERRIES.—Admit plenty of air to plants now in flower, and pollinate the flowers during the warmest part of the day.

PEACHES.—Peach trees which have set their fruits and are now beginning to grow should be disbudded gradually; remove all fruits that are deformed or badly placed.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

SEAKALE.—Batches of Seakale roots should be placed in heat at intervals of eight days during the next three months. They may be placed in large pots or boxes, and grown in any perfectly dark chamber, where a temperature of 60° can be maintained. If large supplies are desired, Seakale may be grown in an underground pit, provided with wooden shutters, and in which beds of leaves can be placed to produce the necessary heat. At Frogmore, we force about 1,200 roots each week in this manner. The roots are placed closely together in rows about 6 inches apart, and the soil is made firm round the roots as they are being placed in position. If the soil is moderately moist, no water is necessary for the first crop, but water may be necessary when it is being dug over a second time.

ONIONS.—Onions raised last autumn may be planted out in rows 15 inches apart as soon as the soil is dry enough. These Onions come into use at a time when spring-sown Onions are either exhausted or grown out to such an extent that they are of little value. They should be planted

on rich ground in an open position. When the plants commence to grow, the soil between the rows may be stirred with a Dutch hoe, and a dusting of soot applied on the approach of rain. Remove all weeds from the seedling rows, and if any plants have been loosened by the removal of those for the fresh plantation they should be made firm by carefully treading the soil on each side of the row.

SHALLOTS.—These should be planted as soon as the soil is dry enough, choosing a light, sandy soil. Plant the bulbs in drills 14 inches apart, and cover them sufficiently to keep the birds from pulling them up. Garlic may be planted in the same way, but should be allowed 18 inches between the rows.

HORSE RADISH.—The present is a good time to make a plantation of Horse Radish. Trench the ground and mix with the soil a liberal quantity of farm-yard manure, so that roots may be grown to the necessary size in the shortest time possible. There are numerous methods of cultivating this crop, but where only a small supply is necessary the best way is to select a number of young roots and plant them in rows 3 feet apart and 1 foot between the plants. A long dibber is the best implement for this purpose. Another method is to make the holes at the necessary distance apart, and drop a piece of root with a crown to the bottom of each hole, allowing the soil to crumble in loosely. By this means, straight roots are obtained, although it may take a little longer to produce them.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

SEED SOWING.—With the advent of February a start must be made in seed sowing. For raising seedlings under glass, square seed-pans are preferable to round ones, unless small quantities of special seeds have to be sown, in which case it is a good plan to plunge the pot in soil contained in a larger one to prevent the seed-pot becoming dry quickly. Except in the case of commoner seeds, square sheets of glass should be provided for each seed pan. Each seed-pan should be made nearly half full with crocks for drainage purposes. In most cases a compost of light loam and good leaf-mould, with a liberal amount of sharp silver sand, may be employed for the compost, and a certain quantity should be sifted very finely. For certain species a little sand-peat may be added with advantage. The soil should be somewhat on the dry side at the time it is used. Press the soil firmly in the pans, give it a good watering, and then, after a few hours, seed sowing may be commenced. Finely-sifted soil should be employed for covering the seeds as evenly as possible, bearing in mind that the smallest seeds only require a very slight covering. Flat seeds, such as those of *Grevillea robusta* and *Hippeastrum* (*Amaryllis*) should be inserted on their edges. Some seeds, such as those of *Acacia lepantha* and of *Caena*, germinate better if they are soaked some hours previous to sowing. Of stove-flowering plants, the following seeds may be sown at the present time:—*Gloxinias* raised in February will flower in late summer, and provide a succession to those grown on from last year. *Clerodendron fallax* succeeds better from seed than from cuttings, and the plants will bloom during August and September. *Torenia Fournieri grandiflora* will flower early and prove extremely useful for indoor decoration during the summer months. *Apheleandra aurantiaca Roetzli* is worthy of a more extensive cultivation; seeds should be sown as soon as they are ripe, and the plants will bloom in late September and October. *Vinca alba*, *V. rosea* and *V. oculata* may all be recommended, and these forms are often obtainable from a single packet of seeds. *Saintpaulia ionantha*, with its effective blue flowers, may be employed as an edging in the plant houses. *Exacum macranthum*, *E. affine*, and *Eustoma Russellianum* (*Lisianthus Russellianus*) are all choice-flowering subjects, but the seeds do not germinate quickly. If *Exacum macranthum* is sown now, the plants may be expected to flower in October; *E. affine* will flower quite three months earlier, but this plant, as well as *Lisianthus Russellianus*, is usually treated as a biennial. In places where there is a large conservatory to be furnished, seedling Abutilons are very serviceable during the summer months, and it is possible that some of the seedlings may be suffi-

ciently distinct to merit keeping. *Nicotianas* such as those of the *N. hispida* type form useful pot plants for flowering in late autumn. *Begonias*, including *B. semperflorens*, *B. Rex*, and those of the tuberous-rooted section may also be sown now. *Celosia pyramidalis* should be sown at intervals to provide a succession of plants. *Streptocarpuses* have been greatly improved in recent years, and they are well worth cultivating for decorative purposes. *Salvias* such as *S. splendens grandiflora*, and *S. s. Zurich* are usually propagated from cuttings, but if the stock is short, plants may easily be raised from seeds. In the case of all the plants mentioned, the seeds should be germinated in a well-heated pit, having a temperature of an ordinary stove. The following seeds may be raised in a cooler house:—*Schizanthus grandiflorus* for plants to follow the autumn-raised stock; *Stalice Suworowii*, *Ten-week Stocks*, *Viscaria cardinalis* and *V. coerulea*. When the seedlings appear, any that show a tendency to become drawn must be placed close to the light, and in some instances they must be removed to a cooler structure.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

TRAINED GOOSEBERRIES AND CURRANTS.—Gooseberry and Currant bushes trained to walls, wires or trellis-work may now be pruned. Examine any branches that have shown signs of deterioration during the past season, and if they are found to be in a state of partial decay at the base, cut them off and train in young wood to refurbish the tree. Black Currants growing against a north wall will furnish a supply of fruit for many weeks after the general crop is over. In pruning Black Currants, train in as much of the young wood as possible without causing overcrowding. Gooseberries as well as Black Currants may be planted in a north or north-west aspect, and will prove equally useful in furnishing a supply of later fruits.

BUSH FRUITS.—Fruit trees trained as bushes, being more or less surface-rooting plants, quickly exhaust the top layer of soil, and an annual mulching or renovation with fresh soil is essential. A mixture of fibrous loam and well-decayed manure, to which a proportion of bonemeal or other suitable artificial manure has been added, forms a suitable top-dressing. Remove all dead leaves adhering to Gooseberry or Black Currant bushes as a precaution against the magpie or Currant moth. This pest is only too common in gardens; it is easily distinguished by its yellow and black body, white wings with blotches of black and sundry yellow markings. In autumn, the grub fastens the edges of a leaf together, and, securing it to the branch, awaits the first appearance of the young foliage to renew its attacks. The Gooseberry, Black Currant, and occasionally the Red Currant are attacked by the magpie moth. All dead leaves should be carefully gathered and burnt. The Red Currant is also liable to attacks of the Currant Clearwing moth, the larvae of which live in the pith of the shoots during the winter, gradually destroying the tree. The part which has been damaged or destroyed by the grub may be seen when the young leaves appear: the infested twigs should be cut away and burnt to destroy the grubs they contain. The planting of bush fruits should be completed during open weather. If planted in quarters or rows in the open ground, allow them a space of 6 to 8 feet each way; if trained against walls or to wires, a distance of 3 or 4 feet apart will be sufficient. Where the pruning of established trees is completed, dig the ground over lightly, adding a surface dressing of manure if necessary.

STRAWBERRIES.—In the case of warm soils, Strawberries are best planted during the early autumn, but spring planting may be safely recommended on soils of a cold, heavy nature. If any planting is to be done, no time should be lost in preparing the ground. Do not add a large quantity of manure to soils of a naturally rich nature, or the result will be an abundance of foliage at the expense of fruits. Although the soil should be moved to a good depth, it is better to rely on surface dressings than to incorporate an excessive quantity of manure, although this does not apply to light soils. Allow a distance of 18 to 20 inches from plant to plant, making the soil firm about the roots as the work proceeds. Reserve a few plants to replace any that may fail.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

DECIDUOUS DENDROBIUMS.—The many species and hybrids of this section are now showing flower-buds in various stages of development. Only the strong, healthy plants should be allowed to bloom, whilst plants which flowered freely last year but failed to make strong growth, should be relieved of their flower-buds in order that the plants may make stronger growth in the coming season. The flowering plants will need a little extra moisture both at the root and in the atmosphere to enable the flower-buds to expand satisfactorily. Any plants which are afforded extra warmth for furnishing early flowers must be treated very carefully if new growths arise from their base, as any excess of moisture is nearly certain to cause some of these tender growths to damp off.

DENDROBIUM WARDIANUM.—This magnificent Orchid will make a brilliant display from the present time onwards. The plants usually thrive and flower luxuriantly for the first few years after importation, but I think it is generally found that they afterwards deteriorate. This being the case, it becomes necessary, when it is desirable to maintain an efficient standard, to replenish a portion of the stock annually with newly-imported plants. As importations are usually received at about the present time, they should be procured at once so that they can be prepared for growing during the summer months. These imported plants should be placed in pans or baskets just large enough to hold them comfortably, using crocks or lumps of charcoal for drainage, and a layer of rooting material consisting of Osmunda fibre two parts, Polypodium fibre one part, and Sphagnum-moss one part. The pseudo-bulbs should be carefully secured to the wires of the receptacle, and it is also a good plan to fix a stake securely in the centre for this purpose. At Westonbirt, *Dendrobium Wardianum* is grown successfully in a light, airy house, where a cool intermediate temperature is maintained; the plants, being suspended from the roof rafters, get the full benefit of sun heat during the summer months. They make strong, thick pseudo-bulbs which flower freely. Newly-potted plants, and especially those that are just imported, will require but very little water for some time to come, but when the young growths have started away from the base, and new roots are multiplying freely in the compost, the supply should be increased gradually until, when the plants are in full growth, an abundance of moisture is given them.

PLATYCLINIS GLUMACEA. The young growths of this spring-flowering species are making considerable progress. During the present period a position at the cooler end of the warmest house, or the warmer end of the Cattleya house, should be afforded these plants. Whilst making their growths they should be given liberal supplies of water at the roots.

THE FRENCH GARDEN.

By PAUL AQUATIUS.

HOTBEDS.—The crops planted on the hotbeds are growing satisfactorily. Every endeavour should be made to keep the plants healthy and growing freely, so that they are ready for gathering at the proper time. As the weather is dull and damp, care must be taken to prevent damping. The Lettuces should have decayed leaves removed directly they are detected. The Radishes need to be thinned where they are crowded, and those near the Lettuces must be removed early, as they generally become wiry through excess of moisture collected by the leaves of the Lettuces, and lack of light. After the paths between the hotbeds have been filled with manure, the mats, when rolled up, are placed in them, to allow as much light as possible to reach the crops. Hotbeds are now formed for forcing Cos and Cabbage Lettuces under cloches. They are built in the same manner as those intended for frames; the manure should be three parts dry and one part fresh, as Cos Lettuce require very little bottom heat. The height of the beds should not exceed 9 inches, and the edges must be placed carefully and firmly to keep the soil in position. When the bed is made, the soil should be placed in a ridge in the centre, and the next row formed before levelling the soil of the previous bed. After this has been done, Bellot

Carrot should be sown very thinly and covered with a half-inch layer of finely-sifted soil. The cloches need to be set alternately in three rows, leaving at least 1 inch space between each in the row, so as to allow sufficient room for tilting them when setting the plants. Three or four days after the completion of the bed, two Cabbage Lettuces, of the variety Little Gott, should be planted on the south side, and one Cos Lettuce in the centre of each cloche.

NURSERY BEDS.—The main batch of Cauliflower for the summer crop should now be sown on a hotbed made about 8 inches thick. The best varieties for sowing are Driancourt and Lenormand; if the soil is of a sandy nature, Chalonnais and Leceuf are preferable. It is not customary to prick out the seedlings of this batch, but during the two last springs "black leg" disease has destroyed many seedlings, and it will therefore be advisable to insert the seeds thicker than usual (about 1,500 seeds per light), and prick out the young plants late in February or early in March. The first Melons (those intended for fruiting in June) should be sown now in trays, 80 to 90 seeds in each tray, and germinated in a greenhouse having a temperature of 60° to 65°. If the soil is in a proper condition of moisture at the time of sowing, water will not be necessary until the seeds have germinated, which will occur after five or six days.

CROPS IN THE OPEN.—Hoe the ground in which August sown Spinach is growing, and remove any dead leaves present. For a succession of Spinach, make a sowing immediately of the variety "Monstrous of Virolloy." At this time of the year Spinach is grown as an intercrop, and is sown broadcast where Lettuces will be planted later on. Spinach has a very uncertain sale, on account of its bad keeping qualities, though it is as a rule, a remunerative crop. It should be marketed in small quantities, as, when there is no demand for it, the leaves will not keep fresh and are wasted. "Ox Heart" Cabbage and silver-skinned Onions that were planted last autumn are doing well; when the conditions are favourable, the ground should be stirred carefully between the rows.

THE FLOWER GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HARRINGTON, K.T., Tynningham, East Lothian.

LUPINUS POLYPHYLLUS.—This species does splendidly cultivated as an annual, and, now that several pretty varieties are obtainable, it is certain to be recognised as indispensable for autumnal display. I have flowered it the same year by sowing in the open, but it is worth the extra trouble to raise the plants under glass. Three-inch pots are a suitable size, placing one seed in each pot. The plants may be put into the border or bed in April. Several of the annual Lupinus are also pretty, but it is too early to sow any of these.

PROPAGATION BY CUTTINGS.—Named varieties of *Lobelia*s can be increased almost indefinitely if an early commencement is made, and variegated *Koniga* and *Mesembryanthemum*, of which a sufficient number of cuttings can usually be had, are just as well rooted now and got out of the way. I propagate these and most other plants rooted at this season in ordinary cutting boxes, which are two-thirds filled with a suitable compost. The boxes are each covered with a sheet of glass and placed over the hot-water pipes in one of the pits. Usually the rooted plants are left in the same boxes until they are wanted for planting. *Salvia splendens* should also be propagated now in order to get fair-sized plants by May; the cuttings may best be rooted in a heated, moist sand bed. *Heliotropes* should be rooted without delay, growing them on to large plants either in boxes or separately in pots. *Fuchsias*, *Plumbago capensis* and other plants requiring to be pruned should be attended to at once, applying but little water until they push into growth again. *Agapanthus* may or may not require water at the root. If the plants are in a perfectly cool pit, the supply may be postponed yet, but they may be divested of dead foliage.

PLANTING.—Border Carnations which have been wintered in pots should be planted without delay. If planted early they have a longer season to become established, and in consequence flower more profusely. It often happens that the weather in February is more favourable for

planting than in March and April. Carnations that were planted in autumn and have failed should be replaced. The live ones should be divested of imperfect and diseased foliage, the soil stirred, and a dressing of soot applied. Hollyhocks should also be planted at the first opportunity for, like Carnations, these do best when established early. It is a mistake to grow these plants in heavily manured ground, as they are most effective when about 9 feet or 10 feet high, and in very rich land they are apt to become taller. My practice is to mass them in the herbaceous border, although the ideal situation is the front of a tall Yew hedge or crepe-covered wall. Montbretias which are growing freely should also be planted. The *Montbretia* is almost hardy, and may survive the cold of many succeeding winters, but a particularly severe frost may destroy them at any time. Plant the strongest corns in groups of four, at a distance of about 4 inches to 6 inches apart. In massing the plants 6 inches of the surface soil should be removed and the ground dug deeply, incorporating with it a good dressing of well-rotted manure. Place the corns in position, and cover them with the surface soil that was removed. *Antholyza pauciflora* may be planted in the same manner, but the corns in this case should be set singly. Herbaceous plants, where the work has been left over from the autumn, may be divided and replanted. Such subjects as perennial Asters, Sunflowers, and other Composites; Aconites, Achilleas, and others that benefit by replanting frequently may be divided at this season. The best effect is produced by arranging small portions of the plants at a distance of 9 inches to 12 inches apart. The division and replanting of these herbaceous plants in spring, result in the plants making shorter stems and blooming a little later than usual. Double-flowered Daisies intended for late blooming should be divided, and the crowns replanted singly in rich soil. Daisies will come true to variety from seed, and seedlings flower later still than plants that are divided in spring.

THE APIARY.

By CHLORIS.

FIXING COMB FOUNDATION.—Those who use the frames with a saw-cut in the top for fixing foundation are aware that the cut affords a favourable hiding-place for the grub of the wax moth, which often penetrates right through the middle of the comb, safe from the reach of the bees, eating and destroying the foundation. Besides this serious objection against the use of split top frames, the cut also weakens the top bar to such an extent that the weight of honey and brood is sufficient to cause the bar to sag.

There is a further objection that 1/2 inch, or even more, of comb is wasted in the slit, and when "starters" only are used nearly 50 per cent. of the wax is thus buried. Some time since I saw an excellent plan for securing the foundation, without employing a groove in the top bar. The wax foundation was fitted in and wired to the frame as described in the issue for February 27, vol. xlv, p. 155. When all the frames had been fitted and wired some wax was melted in an old tin and kept very hot by placing the tin in a pan of boiling water. When all was ready, the wooden guide was placed behind the overturned frame which was tilted at one end, and some of the hot wax poured from a spoon bent specially for the purpose (see fig. 37), allowing a thin line of wax to escape and run down the woodwork and top of the comb securing the two. The hot wax cooled rapidly, and fastened the foundation securely to the wood. The work may be done more neatly by means of wooden blocks made to fit inside of a frame, and about half its depth when laid flat. It is no use attempting this system of securing foundation unless very hot wax is employed, because cool wax will not flow freely, but will set in the wrong place. For this reason it is best to have two spoons, so that one may be heating whilst the other is in use.

SPOON FOR
POURING HOT
WAX.

(The dotted portion shows the spoon before it was bent.)

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 6—
Nat. Chrys. Soc. Ann. Meet. at Carr's Restaurant, Strand, at 7 p.m. Dorchester Gard. Soc. meet. (Lecture on "Annals.")

TUESDAY, FEBRUARY 7—
Scottish Hort. Assoc. meet. Nat. Amateur Gard. Assoc. Concert at Holborn Restaurant, 7.30 p.m.

THURSDAY, FEBRUARY 9—
Soc. Nationale d'Hort. de France (Paris) Exh.

FRIDAY, FEBRUARY 10—
Roy. Gard. Orphan Fund Ann. Meet. and Election of Orphans at Simpson's Restaurant, Strand.

AVERAGE MEAN TEMPERATURE for the ENSUING week deduced from observations during the last Fifty Years at Greenwich—39.2°.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, February 1 (6 P.M.): Max. 35°; Min. 32°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, February 2 (10 A.M.): Bar. 30.7; Temp. 32°; Weather—Slight fog.

PROVINCES.—Wednesday, February 1: Max. 39° Liverpool; Min. 30° Colchester.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Petalums, Hardy Bulbs and Plants, at 12; Roses, Fruit Trees, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

TUESDAY, WEDNESDAY, THURSDAY AND FRIDAY—
Clearance Sale of Fruit Trees and General Nursery Stock at St. John's Nurseries, Worcester, by Protheroe & Morris, at 11.30.

WEDNESDAY—
Herbaceous and other Plants, Hardy Bulbs, &c., at 12; Roses, at 1.30; Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
The Collection of Orchids formed by the late Judge Hullock, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Sir
Charles
Dilke.

It is with the deepest regret that we record the death of the Right Honourable Sir Charles Wentworth Dilke, Bart., M.P., who for many years was Chairman of the Board of Directors of this journal. The late baronet, who was born in 1843, succeeded to the title in 1869, and, although, by reason of his manifold political occupations, he was unable to take the same active interest in the organisation and development of horticulture as that which made his father—the first baronet—a leader in the world of horticulture. Sir Charles Dilke, nevertheless, inherited in no small measure his father's love for nature. The older generation of horticulturists will remember that the first baronet was Chairman of the Committee of the International Horticultural Exhibition of 1866, and that, as stated in our columns on May 15, 1869, the success of that exhibition was due to a very large extent to the indomitable energy and consummate judgment displayed by Sir Wentworth. The conspicuous public services rendered by the late baronet are so well known

and have been so widely acknowledged in the daily Press that there is no need to enlarge upon them here; but the sad occasion of his death may not be allowed to pass without a word of testimony to the extraordinary administrative ability and the fine judgment which characterised Sir Charles Dilke, as illustrated by his work in connection with this journal. The determination of the founders of the *Gardeners' Chronicle*, among whom were Dr. Lindley, Sir Joseph Paxton, Mr. William Bradbury, and Sir Wentworth Dilke, was that it should not only record the progress of horticulture, but play a leading part in ensuring that progress. The tradition established by this group of distinguished men was maintained by Sir Charles. His first pre-occupation was to make the *Gardeners' Chronicle* a worthy representative of British horticulture. Reference has been made in the general Press to the late baronet's encyclopedic knowledge, and in more than one quarter it has been suggested that "omniscience was his foible." Those, however, who have worked in close relation with him know that the suggestion is unfounded. Though possessed of a vast fund of knowledge, Sir Charles had a precise and definite conception of the limitations which are incidental to every man, no matter how well informed. Whenever a topic came under discussion with respect to which he felt himself insufficiently informed, he refused invariably to offer an opinion and insisted that someone with the necessary expert information should be called upon to state a case and give judgment. It was no less the extent of his knowledge than his clear recognition of that of others which made the late baronet such a powerful intellectual force. Sir Charles at home on his eyot of the Thames at Shepperton, or among the heather and pines of Pyrford, revealed to his visitors not only the widely-read and informed politician, but also glimpses of an ardent love of nature and a remarkable power of observation with respect to the world of animals and of plants.

**Adiantum
Farleyense
from
Spores.**

We have received from Mr. Wilke, Curator of the Botanic Gardens, Rotterdam, some interesting particulars on the subject of the alleged sterility of *Adiantum tenerum* Farleyense. According to Mr. Wilke, a fertile sport has originated in the garden of Mr. Bier, at Moordrecht, near Rotterdam, and thousands of young plants have been raised from the spores. The offspring are of the same type as the parent plant and are uniform in character; the pinnules are similar to those of *A. t.* Farleyense; even those which bear spores are not reduced in size. This is the more interesting because *A. Farleyense* is considered to be the sterile form of *A. tenerum*, and the extra development of its pinnules is supposed to be correlated with its sterile habit. Since, however, the pinnules of the fertile plants are quite equal to those of the best forms of the ordinary Farleyense, this would appear to be an untenable hypothesis. It may be true that, just as Farleyense is a variety of *tenerum*, so the fertile plant has also been derived direct from *A. tenerum*, and not through Farleyense, although it so closely resembles that old and popular form as to make its origin

from Farleyense very probable. In any case, it is sufficient to know that for all garden purposes the fertile plant and its offspring are as handsome as Farleyense, and that the fertile plants possess two qualities which will make them of much greater use than Farleyense has ever been. Their fronds are borne on more erect petioles and the plants succeed in a lower temperature than that in which Farleyense can be cultivated. Indeed it is claimed that the plants raised from spores grow perfectly well in as low a temperature as *A. cuneatum*. If, as seems to be the case, *A. Farleyense* has at last and suddenly thrown off its hitherto obstinate sterility, though it is matter of satisfaction to Fern lovers, it is only in accordance with what has been observed among other cultivated varieties of plants; for example, *Solanum tuberosum* and various races of *Primula sinensis*. Further, if *A. Farleyense* has indeed become fertile, it is probable that spore-bearing forms will make an independent appearance in other places in the near future. Indeed, Mr. Wilke informs us that a year ago a plant (see figs. 39 and 40) in Mr. K. Hartlieb's nursery, in Rotterdam, was observed to be showing a tendency to bear spores. In that case, however, the plants never went beyond the stage of forming indusia. It is worth noting, however, that in that case also the frond stems are said to have been more rigid than those of the ordinary Farleyense.

OUR SUPPLEMENTARY ILLUSTRATION.—

The Supplementary Illustration represents *Odontoglossum Groganæ*, the remarkable cross between *O. Uro-Skimmeri* and *O. Edwardii*, two widely-separated species. It was raised by J. HUBERT GROGAN, Esq., Slaney Park, Baltinglass, Co. Wicklow, and shown by him at the Royal Horticultural Society's meeting on November 24, 1908. It is a pretty and free-flowering hybrid, the blooms being produced on stout, branched panicles. The colour is rose-purple, but the lip is rather lighter in shade than the other segments, and it has a yellow crest. Our illustration was taken from a specimen shown in the interesting group of winter-flowering Orchids staged by Messrs. W. BAYLOR HARTLAND & SONS, Ardcairn, Ballintemple, Co. Cork, on November 8, 1910. Mr. HARTLAND kindly sent a photograph of a plant showing its floriferous character even in its early stage of growth, and bearing two seed capsules; this is reproduced in our plate.

R.H.S. OLYMPIA SHOW.—

We have received the following particulars of the Royal Horticultural Society's summer exhibition, which will be held at Olympia, South Kensington, on July, 4, 5, 6. The show is to remain open until 10 p.m. on the first two evenings (July 4 and 5), the price of admission being 1s. The building will be surrounded with a sloping bank of floral groups rising to height of 15 to 20 feet. Within this will be placed table exhibits, including an avenue of Orchids, whilst at the west end, rock and water-gardens will be surrounded by festoon and pillar rose-gardens. Several cups are offered, including one valued at 50 guineas in commemoration of the Coronation of King GEORGE V. The railway companies have been approached with regard to offering special facilities for enabling visitors from the provinces to inspect the exhibition. The secretary has made special arrangements for transit across London for parties of 12 or more. The Royal Artillery band will be in attendance during the time the exhibition is open.

ODONTOGLOSSUM GROGANÆ (O. EDWARDII X O. URO-SKINNERI).

FLOWERS, ROSE-PURPLE.

ROYAL GARDENERS' ORPHAN FUND.—The annual meeting and election of candidates for the benefits of this fund will take place at "Simpson's," Strand, W.C., on Friday, February 10, at 5 p.m. The annual festival dinner has been fixed for Thursday, May 4, when Mr. N. N. SHERWOOD, one of the oldest vice-presidents, has kindly consented to preside.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual general meeting of the members of this Society will take place at Carr's Restaurant, 264, Strand, on Monday, February 6, at 7 p.m. The President, Sir ALBERT ROLLIT, will occupy the chair.

NURSERY FIRM'S ROYAL WARRANT.—MESSRS. JAMES CARTER & Co., Raynes Park, have been appointed, by Special Warrant bearing the date January 17, 1911, seedsmen to the EMPEROR of GERMANY.

FLOWERS IN SEASON.—MESSRS. R. VEITCH & SON, Exeter, have forwarded specimens of shrubs in flower in January in their Exeter nursery. The subjects include *Garrya elliptica*, Grevillea, with pretty red flowers in bunches and Rosemary-like foliage; *Acacia Baileyana*, a small edition of the *Mimosa* (*Acacia dealbata*), but not fragrant; *Hamamelis arborea* and *H. Mollis*, of which, though the former blooms more freely, the latter has a much finer flower with a decided perfume; *Chimonanthus fragrans*, of delightful perfume; *Lonicera Standishii*, with small creamy-white flowers without the spur generally characteristic of the Honeysuckles; *Prunus Davidiana alba*, like a small single *Deutzia*; and a *Cotoneaster angustifolia*, of attractive appearance by reason of its brightly-coloured berries.

SURVEYORS' INSTITUTION.—The next meeting will be held at the Institution on Monday, February 6, when a paper will be read by Mr. WILLIAM WOODWARD on "The Evolution of Fire-resisting Construction." The annual dinner will be held at the Whitehall Rooms, Hotel Metropole, on Tuesday, February 28, at 7 p.m.

GATTON PARK, SURREY.—The February number of the *Art Journal* contains a long and interesting account of Gatton Park, the property of Sir JEREMIAH COLMAN, Bart., V.M.H., with views of the mansion, pleasure grounds, and gardens. Some of these are from photographs by Mr. W. E. GRAY, and others from paintings by BIRKET FOSIER, CHARLES DAVIDSON, and other celebrated artists in the gallery at Gatton Park.

RETIREMENT.—Mr. JOHN P. ALLAN, who for the last 26 years has been manager of the seed and bulb department of Messrs. CLIBRANS, of Altonham and Manchester, is retiring from his position on account of impaired health. Mr. ALLAN is well known amongst gardeners and farmers throughout the North of England and in Scotland. His many friends will hope that relaxation from business will restore him to health.

"WHITE" MEDALLIST.—The medal given by the Massachusetts Horticultural Society in honour of GEORGE ROBERT WHITE (see *Gardeners' Chronicle*, January 7, p. 11), has this year been conferred on Mr. JACKSON T. DAWSON of the Arnold Arboretum. It is gratifying to learn that Mr. DAWSON, whom the American Press proclaims has few equals as a gardener, is an Englishman, being a native of York. In his capacity as Superintendent of the Arnold Arboretum, he has become one of the first authorities on trees, and has raised many new plants, including a type of Rambler Roses; one of the varieties, "The Sargent Rose," formed the supplementary issue to *Gardeners' Chronicle*, November 12, 1910.

GLASGOW FLOWER SHOW.—It is proposed to hold a flower show in Kelyvingrove Park, Glasgow, on a large scale, on September 6, 7, 8, in connection with the Scottish National Exhibition, which is being promoted for the purpose of endowing a chair of Scottish history in the Glasgow University. Arrangements have lately been completed between the National Exhibition

authorities and the directors of the Glasgow and West of Scotland Horticultural Society whereby the flower show will be held under the auspices of this society. It has been decided to offer £400 in cash, besides cups, medals and other prizes. The secretary of the Society is Mr. HUGH M. MYKIE, C.A., 124, St. Vincent Street, Glasgow.

FIG. 29.—MR. TIER'S FERTILE PLANT OF ADIANTUM TENERUM FARLEYENSE.

FIG. 30.—MR. HARTILL'S PLANT OF ADIANTUM TENERUM FARLEYENSE WHICH SHOWED SOME SIGNS OF APPROACHING FERTILITY.

NEW SOCIETY FOR ULSTER.—The Ulster Rose and Floral Society has been recently instituted for the purpose of holding flower shows in the north of Ireland. Floral exhibitions have formerly been held in connection with the Royal Ulster Agricultural Association's show, but, as it has been decided to discontinue these, the new society will take over the work. It is proposed to hold the first exhibition in the Botanical Gardens Park, Belfast, on July 21 and 22. Subscriptions have already been received amounting to a considerable sum, and there is a guarantee fund amounting to more than £100. The provisional committee includes such well-known names as Messrs. W. H. Calvert, T. S. Crozier, Alexander Dickson, Hugh Dickson (Belmont), H. D. M. Barton, Mrs. Edwin Hughes, Alexander Dickson, Hugh Dickson (Newtownards), Samuel McGredy (Portadown), Dr. Campbell Hall, J. S. B. Larmour, H. E. Richardson, Colonel R. G. Sharman-Crawford, D.L., Frank Thorpe, Frank E. Smith, Edward Cowdie, and James Brand. Messrs. H. J. Pinkerton and J. A. Stewart have been appointed joint secretaries.

STRAWBERRY LEAF SPOT.—The fungous disease known as Strawberry Leaf Spot and sometimes as Bird's Eye Spot is the subject of Leaflet No. 243 of the Board of Agriculture. The presence of the fungus, which sometimes causes considerable loss to growers, may be recognised by the reddish-brown spots on the leaves of diseased plants. The spots subsequently become of an ashy-grey or whitish colour bounded by a reddish border. Like so many other serious pests, the fungus responsible for Strawberry Leaf Spot produces both summer spores, which carry infection from leaf to leaf during the growing period, and winter spores which, germinating in spring, renew the infection year by year. Syringing is recommended as a remedial measure, either with liver of sulphur (1 ounce to 3 gallons of water) or with Bordeaux mixture (10 lbs. copper sulphate, 8 1/2 lbs. lime, to 100 gallons of water). In badly diseased cases the drastic method of burning the beds has proved successful. After the fruit is gathered the beds are mown, covered with dry leaves, straw or dry litter, and then burned. The new foliage indicates decisively that the plants have not suffered, and that the pest has been eradicated.

WHOLE-MEAL BREAD.—Should the experiment recently made by Sir OSWALD MOSTEY in enabling his neighbours in Staffordshire to obtain whole-meal bread prove successful, it may have far-reaching effects in destroying the popularity of the inferior whiter bread, made from roller-ground flour, and now in general use. Doubtless, if people only ate bread for the sake of appearance, there would be something to be said for the latter type; but since bread is eaten for purposes of nutrition, it is little short of absurd that the bread consumed should be made after the more nutritious part of the Wheat-grain has been removed. The facts are these: the husk of Wheat contains a large proportion of mineral substances (phosphates, etc.), which are of high nutritive value. Hence the feeding properties of brown bread, which, however, is not found to be digestible by everybody. Just beneath the husk of Wheat are rich stores of nitrogenous and other nutritious substances, which are apt to be removed by modern methods of milling, with the result that ordinary bread is made from the least nutritious part of the grain. It is very white, and looks nice. It is very soft, and hence appears to be in large measure responsible for bad teeth, so deplorably common among the school children of this country. Bad teeth, in turn, are responsible for all manner of ailments and diseases. Hence the indictment of the

modern loaf seems to be complete, and everyone should endeavour to obtain bread which shall have less decorative and more nutritive value.

FORESTRY.

SALE OF OAK TIMBER.

ONE of the most remarkable sales of Oak in recent years was carried out on January 24 by Messrs. Richardson & Son, of Stamford. These Oaks grew on the Farming Woods Estate, near Brigstock, Northamptonshire, and formed part of the old historical Rockingham Forest.

The Rockingham Forest is famous not only for its splendid Oak timber, but also for the occurrence amongst it of the peculiar form which is called Brown Oak. Little is known by the outside public of this beautiful timber, which is not mentioned in ordinary books on forestry, and does not appear to exist on the Continent, being a strictly English product, more or less limited to the Midland and Eastern counties. It appears to have been first described by Mr. Elwes in *Trees of Great Britain*, ii., 337 (1910). Brown Oaks occur sporadically, and are characterised by having a brownish heartwood, which, when (as is often the case) of a beautiful rich colour, is much valued for panelling and for making furniture. It is especially prized in America, where it is used in the ornamentation of Pullman cars, &c. The great dining-room in the White House, at Washington, is entirely panelled with English Brown Oak. The cause of the peculiar brownish coloration is unknown, though we hear that some experiments (not yet completed) which have been made at Cambridge, point to its being due to the absorption of iron from the soil in which the trees are growing.

Several of the Oaks for sale were believed to be brown, and one of these fetched £41. The total number of Oaks sold was 105, averaging £21 a tree; but some reached remarkable figures, the biggest tree realising £105, while the second best, the "King Oak," sold for £76. These old Oak trees were mostly growing in a park in open order, not drawn up by dense trees around them, and had short boles, which were, however, of great diameter. The dimensions of one tree—an average specimen—were:—

19 feet long, 38 inches quarter girth =	190
4 feet long, 35 inches quarter girth =	34
Tops =	20
Total	244

The Oaks on this property are famous for the quality of their wood which is usually sound to the base, without flaws or cracks, and with very little sapwood.

In addition to the Oaks, a few Ash were also sold, 19 trees averaging £13 a piece; the largest and finest specimen realising £25.

The amount of fine Oak timber still remaining on this estate is enormous, and we understand that the present sale will not be the last. X.

SCOTLAND.

NOTES FROM SOUTH-WEST SCOTLAND.

SAXIFRAGA × KESTONIENSIS.

THIS, I suppose, is one of Mr. G. Reuthe's *Burseriana* hybrids, and an exceedingly choice and vigorous one. It is in full flower now (January 27) on a high, exposed ledge of the wall garden. This year and last it has been the earliest Rockfoil to flower. *S. Burseriana* major began to bloom on January 24, and *S. Burseriana* is opening its first blossom to-day. *S. kestoniensis* has the pure white petals of its parent, with golden anthers and bright red stems 5 inches long. *Leucoium carpathicum*, *Hepatica angulosa*, *Cyclamen vernum* and *Coum*, and winter *Aconites* lighten up our borders well just now; *Scilla bifolia* comes as pioneer of its race; *Iris stylosa* has been giving a few flowers since November; the woods are sheeted with Snow-drops, and they would be equally full of *Crocuses* if rabbits and pheasants would let them alone. The spell of mild weather has tempted *Rhododendron barbatum* to unfold its blood-red trusses, quite eclipsing the softer glow of *R. × Nobleanum*, which is covered with bloom. *R. × præcox* is giving the first glimpse of the rosy cloud in which it will be enveloped presently. *Ilanamelis arborea* is sheeted with dull gold and maroon; one of my plants is 30 years old, but its glory is put to shame by the clearer flame of *H. mollis*, which I class with the summer-flowering *Buddleia variabilis superba*, among the finest real acquisitions of late years. Another splendid winter-flowering shrub is *Berberis nepalensis* (Bealei), which began to flower before Christmas, and is now loaded with fragrant blossom. Too often one sees this noble Barberry crowded up with coarser shrubs which make it grow leggy. Give it plenty of room and light, with shelter from rough winds, and there are few flowering shrubs that produce such handsome foliage. *Herbert Maxwell, Monroith.*

INSTRUCTION IN HORTICULTURE.

THE governors of the Edinburgh and East of Scotland College of Agriculture are considering a suggestion, placed before them by the Scottish Horticultural Association, for a two years' course in horticulture at the college. A scheme was submitted by the committee, which had approved of the proposed curriculum, but it was decided to first submit the details to the Scottish Horticultural Association for the consideration of that body. It was mentioned that practically all the work involved in the course could be undertaken by the College, except that it might be found necessary to appoint an assistant lecturer in horticulture, and to make special arrangements for conducting certain of the classes.

ALLEGED FRAUD.

AT Glasgow Police Court on the 24th ult., a young man, who was described as a working gardener, was remitted to the Sheriff on a charge of having devised a scheme to obtain money by false pretences. It is alleged that the man wrote to a registry office in Oban and an emigration office in Forfar to the effect that "the Scottish Gardeners' Association, Glasgow, desired to arrange a scheme of emigration to Canada." It is alleged that part of the scheme was that passage money should be advanced by the association, and the money deducted from the first year's wages. It is said also that the letters stated that the association had lost money last year owing to several of the parties engaged having failed to put in an appearance, and it was thus necessary that each applicant should deposit £1 for booking fee. Married couples were also required, according to the letter, and part fares would be advanced. A large number of applications are said to have been received, 77 having been engaged at Oban, and £96 received and banked there; while between 40 and 50 were engaged at Forfar. It is also alleged that the agents were written to, asking that the money

should be sent to the accused, but that the correspondent in Oban only sent the names and addresses of the intending emigrants, but wished some guarantee before forwarding the money; and further that the accused called at several addresses in Glasgow, and said that if 3s. 6d. were paid food would be supplied in the train from Montreal. It is believed that all the money obtained by the accused was a few sums of 3s. 6d. received for food tickets.

A GARDENER'S COMPENSATION CASE.

SHERIFF-SUBSTITUTE BAILLIE has just issued in the Hawick Sheriff Court his decision in an interesting compensation case which was entered in court some time ago. The claim was made by Mrs. Reid, widow of Mr. Robert Reid, gardener to Mr. Charles J. Wilson, Deanfield, Hawick,

THE IMPERIAL DEPARTMENT OF AGRICULTURE IN THE WEST INDIES.*

In recent years the productions of tropical countries have been in increasing demand to supply the raw material for the manufacturing industries on which the prosperity of this country depends.

In the case of large commodities like tea, cocoa, and rubber, these can only be obtained from the tropics. It is admitted that the British are in possession of some of the richest portions of the tropics, and it is, therefore, a matter of Imperial interest that we devote time and attention to their development, and appreciate at their true value efforts to make the best of them.

Speaking roughly, there are about three million

West Indies, in the larger sense suggested above, cover an area of 109,836 square miles, or a little less than the British Isles. The population is estimated at 2,300,000. The value of the total trade is about £22,000,000. Of their imports they take about 40 per cent. from the United Kingdom; so that, in spite of their nearness to the United States, these Colonies continue to take a large share of their manufactured and other goods from the Home Country. An increase in the total trade from £15,647,816 in 1905 to £21,429,301 in 1909 is also encouraging.

Not long ago Sir Charles Lucas, who is so intimately acquainted with Colonial matters, happily remarked that, while the 18th century saw the greatness of the West Indies, the 19th their distress, the 20th century, he hoped, would witness their regeneration. The latter, in part, is becoming true, for Lord Greve, the late Secretary of State, was in a position to announce in February last "that no West Indian Colony was now in receipt of grants in aid."

I now come to the work of the Imperial Department of Agriculture in the West Indies. This Department was created on the recommendation of a Royal Commission consisting of Sir Henry Norman (chairman), Sir Edward Grey, and Sir David Barbour. In 1897, when the Commission visited the West Indies, many of the Colonies were in a depressed condition, and a source of anxiety to the Imperial Government and to those directly interested in them. The Commission was charged, in the first place, to inquire into the condition and prospects of the sugar-growing colonies and "suggest such measures as would appear best calculated to restore and maintain the prosperity of those colonies and their inhabitants." A further subject of inquiry was: "Whether in the event of the production of sugar being discontinued or considerably diminished, what other industries could replace it, and be carried on profitably and supply employment for the labouring population."

In their report, which appeared in the autumn of 1897, the Commissioners stated that in most of the West Indies the products of the Sugar-cane constituted by far the larger proportion of the total exports of native produce, and that, in the event of a failure of the sugar industry, the welfare of each colony would then depend on the extent to which it might be possible to establish other industries.

The Commissioners recorded as their opinion that the depression in the sugar industry was due "to the competition of other sugar-producing countries, and, in special degree, to the competition of beet sugar produced under a system of bounties." They submitted that "the best immediate remedy . . . would be the abandonment of the bounty system." In the meanwhile, they recommended certain special remedies, such as improved steam communication with outside markets and between the different islands, and the organisation of a scientific department to assist the sugar industry and encourage, where conditions were favourable, minor agricultural industries, together with a general improvement in the system of cultivation of the principal crops.

Most of the recommendations were, sooner or later, adopted by the Imperial Government, including the creation of an Imperial Department of Agriculture. For the latter, on the motion of Mr. Chamberlain, funds were voted by Parliament on August 2, 1893. The average amount that has been expended up to 1908 has been at the rate of £17,400 per annum. Of this amount, some £5,000 represented the cost of the head office; the remainder was applied in grants-in-aid of botanical and experiment stations, agricultural schools, and other educational services in the individual colonies. Up to March, 1906, grants were allotted to Jamaica to provide the services of an agricultural lecturer, to British Guiana to assist in improving the sugar industry by means of research work and experiments, and to Trinidad in providing for the establishment and maintenance of a botanic and experiment station at Tobago. The Imperial Commissioner of Agriculture established his headquarters and that of the central staff and the laboratories and library of the Department at Barbados, as the more central point from which to visit the other colonies. He was charged with the duty of administering the agricultural grants in the colonies of Grenada, St. Vincent, St. Lucia, the Leeward Islands, and Barbados, and was consulting officer in agricultural matters to the

FIG. 40.—FROND OF MR. HARTLIEB'S PLANT WHICH DEVELOPED INDUSIA.

under the Workmen's Compensation Act, for £198 5s., being three years' wages, as compensation for herself and her two children for the death of her husband. It was stated that the deceased, who was in Mr. Wilson's employment as gardener, returned home on a Sunday morning in August after being at the garden, and injured his thumb-nail when he was brushing the garden soil off his boots; it was alleged that the tetanus bacillus entered the wound, and that he died from blood poisoning. It was claimed that this bacillus is commonly found in garden soil, especially in that in which horse manure is used. Mr. Wilson was insured against liability, and the insurance company defended the claim on the ground that the injury was not an accident arising out of or from the employment. The Sheriff upheld the contention of the company, and dismissed the action with costs.

square miles (1,920 million acres) of British territory lying within the tropics; the total population is about 300 millions, while the total value of the exports are estimated at not less than 230 million sterling. Our responsibilities in regard to so vast an area can hardly be realised; but if our commercial supremacy depends upon the control of the tropics, we cannot shirk our duty, either in the interest of our possessions or in our own interest.

In my remarks this evening I shall confine myself more particularly to the circumstances of the West Indian Colonies—that is, to the tropical possessions of the Crown, consisting of the groups of islands generally known as the British West Indies, Bahamas, and Bermuda, together with the two considerable Colonies on the mainland, viz., British Honduras and British Guiana. The

* Paper read by Sir Daniel Morris, K.C.M.G., D.C.L., D.Sc., F.L.S., at the Royal Colonial Institute, on January 10, 1909. The Right Hon. Lord Brassey, G.C.B., in the chair.

Governors of Jamaica, British Guiana, and Trinidad.

The duties entrusted to the Department were the general improvement of the sugar industry and the encouragement of a system of subsidiary industries in localities where Sugar could not be grown, or where the conditions were more favourable for the production of Cacao, Coffee, Bananas, Oranges, Limes, Cotton, Rubber, Coco-nuts, Sisal-hemp, Rice, Nutmegs, Pine-apples, and other crops.

In addition, it was proposed that it should devote attention to the improvement of the breed and condition of cattle, horses, and small stock, and to the extension of bee-keeping for the production of honey and beeswax.

As it was realised that substantial progress was impossible until the mass of the people (wholly dependent on the products of the soil) were brought into sympathy with agriculture, and trained to regard the successful treatment of crops as the basis upon which to build, not only their own welfare, but the general prosperity of the colonies, a prominent position was given to teaching the principles of elementary science and agriculture, both in the primary and secondary schools. Associated with this policy was the increased attention devoted to object-lessons, the encouragement of growing specimen plants in pots and boxes, and the establishment of school gardens. Arbor days for the public planting of ornamental and other trees were also organised and assisted by the Department.

The average expenditure on scientific investigations of matters directly affecting the sugar industry at Barbados, Antigua, St. Kitts, and British Guiana was at the rate of nearly £4,000 per annum. The investigations have been mainly directed to raising new seedling varieties of canes capable of withstanding diseases that had rendered the continued cultivation of the Bourbon cane impossible in some localities, and a larger yield of sugar per acre.

The results of the sugar experiments carried on by the Department have proved of great service to the planting community in the West Indies, and they have also been shared in by other countries, such as the Southern United States, Australia, Natal, and Mauritius. It is estimated that fully one-half of the canes now cultivated in the West Indies are new canes, yielding, over large areas, mean results ranging from 10 to 25 per cent. higher than the older varieties.

At a recent West Indian Conference, Mr. Bovell, who has been in charge under the Imperial Department of the sugar-cane experiments at Barbados since 1898, stated "that more profit was derived from the introduction of new seedling canes on one estate in Demerara than would cover the whole cost of the experiments at Barbados over a period of 26 years."

It may be within recollection that the Royal Commission of 1897 drew attention to the danger that the West Indian Colonies incurred in their dependence on a single industry, and their recommendations were largely directed to the desirability of establishing other and alternative industries. The result of this policy during the last 12 years is shown in the fact that, while the total exports of produce and manufactures of the West Indian Colonies have increased from £5,625,000 to £7,195,360, the exports of the products of the Sugar-cane (sugar, rum, and molasses) have declined from £3,243,000 to £3,037,660. On the other hand, the exports of other commodities, such as cacao, fruit, cotton, logwood extract, tobacco and cigars, rice, coco-nuts, and rubber, have increased from £1,582,000 to £4,157,700. The recent Royal Commission entirely concurs with the Commission of 1897 as to the danger of dependence on a single industry, and they strongly support a continuance of the efforts that have been made with such signal success to develop other industries suitable to the soil and climate. At the same time, they recognise that the sugar industry is still, as in 1897, the dominating factor in such colonies as British Guiana, Barbados, St. Lucia, Antigua, and St. Kitts. In Jamaica the percentage of sugar products is 12.6, as against 18 in 1896, and in Trinidad 24.7 per cent., as against 57 in 1896.

An instance of the value of scientific investigation for practical purposes was strikingly brought out by an officer of the Department in the case of the moth-borer of the Sugar-cane. For something like 200 years this borer had been regarded as the most destructive and most widely-distributed of the enemies of the Sugar-cane. Little,

however, was known of the early stages of its growth, and the eggs, and how and where they were deposited had never been observed. The loss caused in some years by the moth-borer amounted to several thousand pounds in each of the sugar colonies. It was important, therefore, that its life-history, from the egg to the mature insect, should be fully worked out. When, in 1900, Mr. Maxwell Lefroy was appointed first entomologist of the staff of the Imperial Department of Agriculture, he was entrusted with the task. He had come straight from Cambridge and probably had never seen or touched a Sugar-cane in his life. Under these circumstances, the prospect of success might be regarded as not encouraging. But after a patient and exhaustive inquiry, extending over nearly a year, Mr. Maxwell Lefroy succeeded in finding the moth-borer eggs deposited in a greenish cluster on the back of the leaf of the Sugar-cane. They were so inconspicuous that they had escaped the notice of successive generations of planters, who had only realised the presence of the moth-borer by the injury it had done to their canes. The result of Mr. Maxwell Lefroy's discovery was to place at once within reach of the planters the complete story of the moth-borer, together with simple and effective means of controlling it. He also found that a minute parasite attacked the eggs, and if, in addition to collecting the eggs, the parasites were protected, the moth-borer might be largely kept in check by natural means.

Next to sugar the cacao industry is the most important of any in the West Indies. The total value of the exports amounts to about a million and a half sterling. The diseases affecting Cacao trees have received careful attention, and planters have been kept fully informed as to their character, and the treatment likely to produce the best results. Experiments in manuring Cacao plantations have been carried on at Grenada, St. Lucia, and Demonica with very satisfactory results. The grafting of Cacao in order to establish trees yielding large crops of the best qualities has been successful on a moderately large scale at Demonica. In St. Lucia, as the result of the establishment of experiment plots by the Department, it was reported that the "planters in that island were now importing basic slag and sulphate of ammonia, and pruning and forking had, for the first time, become a recognised part of Cacao cultivation."

It was recognised from the first that local experiment stations distributed on the estates and carried on with the co-operation of individual planters and the scientific officers of the Department were the best and most potent means of demonstrating the lines on which science could be of service to agriculture. This enabled the planters to understand the value of scientific methods of research, and, on the other hand, to bring the scientific workers into sympathy with the difficulties and limitations of the practical side.

Increased interest is being taken in Tobacco-growing in the West Indies, and especially in Jamaica, where, in addition to the considerable local consumption, the exports of tobacco, cigars, and cigarettes are of the annual value of £40,000. Experiments in Tobacco-growing have been carried on for some years in Trinidad, and also in St. Vincent, St. Lucia, Antigua, and St. Kitts.

(To be continued.)

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

APPLE CULTURE IN DEVONSHIRE.—The description of the neglected state of the Apple orchards in Dorset (see pp. 33, 51) is, I am afraid, equally applicable to many other counties. In the contiguous county of Devon, and perhaps more particularly in East Devon, I can confirm every word written by Mr. Carnegie-Cheales in the matter of neglect and waste as being fully repeated; indeed, it is so apparent that even visitors or inexperienced people make uncomplimentary comments on the ignorance and apathy of the owners. The condition of the orchards in this part of the county is lamentable; trees that were blown down or half uprooted yesterday are left to remain in the position in which the forces of nature have put them, apparently with the hope that the same

forces will kindly come and put them upright again. It is no uncommon thing to see uprooted Apple trees lying in the same position for months, and even years, the dead and dying branches often intermingling with those of a neighbouring tree. The branches, which are never touched by a pruning knife, are covered with lichen, often from the level of the ground to the ends of the farthestmost branches. The fruits for the most part fall from the trees and are raked up into heaps on the ground, where they are left for weeks, and are removed in ordinary farm carts to the cyder-making house. The habit of pasturing cows and horses in Apple orchards referred to by Mr. Carnegie-Cheales as being in vogue in Dorset is by no means unknown in Devon. That the general conditions, both of soil and climate, in Devonshire are favourable to the profitable growing of Apples is, I believe, acknowledged, and the excellent condition of some few areas of land under culture of fruit, vegetables and flowers skirting the railway between the city of Exeter and the coast town of Exmouth, as well as a few others in different parts, afford conspicuous object lessons. The evidence of neglect is, however, not only seen in fruit-growing, but in arboreal vegetation generally. Ivy makes a very rapid growth in Devonshire: trees, shrubs and houses, and even churches, soon get covered with it. I know of an instance in which the Ivy on the wall of a house entered a living room through a slight aperture between the bricks and the window frame and began to attach itself to the wall inside, but the owner all the while objected to cut it back. *John R. Jackson, Claremont, Lympstone, Devon.*

BRITISH AND FOREIGN APPLES.—It is evident that *A* (see p. 58) contented himself with a very cursory glance at my note on page 43, for I carefully mentioned America as the place of origin of the "foreign" Apples of which I write. America nowadays is the name generally applied to the United States of America, and does not include Canada. I am well aware that quantities of splendid Apples are sent to our markets from British Columbia, Canada, and Tasmania, but does *A* mean to suggest that these are the same as British-grown fruits, from an economic point of view? My object in writing was to point out a means whereby our growers could easily supply what the great majority of the purchasers want. Of course there are plenty of home-grown Apples available in mid-winter, and, equally, of course, there was an eager demand for the excellent fruit staged at the R.H.S. meeting. No doubt *A* knows quite as well as I do the motives which actuate the average buyer; but the fact remains that, as a rule, home-grown Apples do not command so high a price in our shops as imported or foreign fruit. *A. C. Bartlett.*

FRUIT-TREE STOCKS.—Mr. Taylor's note on p. 58 has induced me to look further into the subject. There is no doubt that grafting was a branch of horticultural science which exercised the minds and ingenuity of the religious from the earliest time. Manuscripts of the works of Varro, Columella, Virgil and Palladius were of frequent occurrence in the monastic libraries of the Middle Ages, and each one of these great writers enter in great detail into the several methods in operation in their day. It is clear, then, that the first rudiments of horticultural science must have been introduced into this country by the Romans, as these writings show us that the fruits cultivated by that people at the zenith of their rule included with few exceptions those now in culture in the United Kingdom. The earliest English author who has treated on the subject of grafting, and that only incidentally, is Alexander Necham, a learned master of the Grammar School at St. Albans at the close of the 12th century, and afterwards Abbot of Cirencester (A.D. 1157 to 1217). His valuable and comparatively unknown work, *De Naturis Rerum*, is a sort of commonplace book, wherein he entered under various heads the gleanings of his secular and theological knowledge. He makes few practical remarks, but he states sufficient for us to know that he was acquainted with the process of grafting the Pear on the thorn. He also remarks that an Apple swims when thrown in water while a Pear will sink. The usual method of increasing one's stock in those days appears to have been from sets or

cuttings. Necham states that slips of Peaches were planted in the Royal Garden at Westminster in the fourth year of Edward I., 1276. John Gardener, who wrote *The Fate of Gardening* about 1440, directs the stocks of grafts of both Apples and Pears to be planted in January, the Apple on an Apple stock and the Pear "upon a Hawthorne." The Hon. Mrs. Evelyn Cecil has a good deal to say about this old writer in her excellent *History of Gardening in England*. Donald McDonald.

ADIANTUM FARLEYENSE GLORY OF MOORDRECHT.—This very beautiful variety of Maiden-hair Fern, exhibited at the Royal Horticultural Hall by Mr. A. A. Fabius, Redlands Nursery, Emsworth, on Tuesday last, deservedly obtained an Award of Merit as a distinct variant of that beautiful Fern *A. Farleyense*. It appears to have originated from a sport of *A. Farleyense* which from time to time has been reported as fertile, though, until now, no spores have been obtained. The new variety, however, is fertile, and comes quite true from its spores. It strongly resembles the parents, but the pinnales are prettily crisped, the habit is more erect, and its growth apparently from the huge size of the specimen, more robust. It is also claimed for it that it requires less heat than *A. Farleyense*, the specimen shown having been grown under the same cool conditions as *A. cuneatum*. It originated in the nursery of Mr. J. Bier, Moordrecht, Holland. C. T. D.

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 31.—The usual fortnightly meeting was held on Tuesday last in the Society's Hall, Vincent Square, Westminster. The exhibition was a small one, but the attendance was much larger than on recent occasions.

The exhibits of Orchids were remarkably good, and the ORCHID COMMITTEE granted several awards to novelties, including two First-class Certificates and four Awards of Merit.

The principal exhibit before the FLORAL COMMITTEE was a collection of forced shrubs staged by Messrs. R. & G. CUTHBERT, a Gold Medal being awarded. There were several exhibits of hardy bulbous and other early-flowering plants, greenhouse plants, Carnations, Cyclamens, Pelargoniums, and Ferns. Only one Award of Merit was made by the FLORAL COMMITTEE, this being given to a variety of *Adiantum Farleyense*.

The principal exhibits in the fruit and vegetable section were of Apples and Onions. The FRUIT AND VEGETABLE COMMITTEE made no award to a novelty.

At the three o'clock meeting in the Lecture Room, more than 80 new Fellows were elected, and a series of coloured photographs, prepared by Mr. W. Marshall, Henley-on-Thames, was shown as lantern slides. The room was filled to overflowing, and the pictures were greatly enjoyed by the company.

Floral Committee.

Present: Henry B. May, Esq. (in the Chair); and Messrs. Chas. E. Shea, George Paul, W. J. James, F. Page Roberts, W. P. Thomson, Ed. Mawley, Chas. Dixon, C. Blick, James Douglas, W. Howe, J. E. McLeod, George Gordon, G. Reuthe, W. J. Bean, Jno. Green, Jas. Walker, C. T. Drury, W. B. Cranfield, Herbert J. Cuthbert, Jno. Jennings, E. H. Jenkins, Chas. E. Pearson, and R. Hooper Pearson.

The exhibit of forced flowering trees and shrubs shown by Messrs. R. & G. CUTHBERT, Southgate, was of very large extent, and presented a showy bank of flowers. Profusely-flowered plants of *Rhododendron* (*Azalea*) *sinense* and dwarf Lilacs formed the groundwork, with Palms, Acers, and Ferns as relief. Tall standards of other subjects were interspersed throughout the group, with bold masses of Magnolias at intervals. The Magnolias included *M. Lennet*, *M. speciosa* (exceptionally well flowered), and *M. conspicua*. Other subjects included *Staphylea colchica*, *Laburnums*, *Wistaria sinensis*, *Choisya ternata*, *Forsythia suspensa*, *Spiræa Thunbergii*, *Hamamelis arborea*, and *Pyrus atrosanguinea*. (Gold Medal.)

Messrs. JAMES VEITCH & SONS, Chelsea, filled a large table with indoor flowering plants, all

shown in excellent condition and arranged with skill. A pretty group was made with *Rhododendron* "The Comtesse" (blush) at the back, *Cytisus scoparius* *præcox* (white), *Rhododendron* (*Azalea*) *amurum* "Hexe" (rose), with *Choisya ternata* at either side. The strain of *Primula obconica* exhibited by this firm was remarkably fine, some of the plants being as showy as *P. sinensis*. In this case a background was made with *Eupatorium vernale* and *Erlangea tomentosa*. There were also profusely-flowered *Azaleas*, *Camellias* in small pots, with a row of *Freesia refracta* alba, and varieties of javanico-jasmaniflorum hybrids of *Rhododendron*. (Silver-gilt Banksian Medal.)

Messrs. W. CURBISH & SON, Highgate, had also a fine display of forced plants, *Magnolia Soulangiana amabilis*, *Camellias*, *Liliums* in variety, *Azaleas*, *Boronias*, *Astilbe* (*Spatang*) *japonica*, *Daphnes*, and *Ericas* being well shown. This firm also displayed an attractive rock-garden exhibit, their bulbous Irises being very choice. These included *L. reticulata grandiflora* (of a beautiful dark-blue shade), *L. Danfordiae* (yellow), and *L. × Sind-pers* (pale blue with yellow crested). *Crocus vitellinus*, *Adonis amurensis*, *Soldanella alpina*, *Daphne Blagayana*, and *Tulipa Kauffmanniana* are other interesting plants shown in flower. In addition to these, Messrs. CURBISH displayed a collection of perpetual-flowering Carnations. (Silver-gilt Banksian Medal.)

Mr. L. R. RUSSELL, Richmond, again displayed Orange trees in fruit and *Debrugea velutina*. Small plants of *Rhododendron amurum* "Hexe" were covered with their pretty rose-coloured flowers. But the most interesting plants were small specimens of *Francisca calycina floribunda*, each, although only a few inches high, having large inflorescences of pale-blue flowers.

Messrs. H. CANNELL & SONS, Swanley, Kent, showed varieties of Zonal Pelargoniums and greenhouse Cinerarias. The Pelargoniums made a showy patch of colouring, the varieties *Saxonia* (scarlet), *New York* (scarlet), *Hibernia* (brick-red), *Snowdrop* (white), *Queen of Italy* (salmon-pink), and *Frogmore* (magenta and crimson) being a selection. (Silver Banksian Medal.)

Messrs. STUART LOW & CO., Enfield, were the exhibitors of a bright group of Carnations, well-bloomed Cyclamens, including their popular Salmon King variety; also a few greenhouse plants in bloom, such as *Streptozia Regina*, *Acacia Baileyana*, *Correa cardinalis*, and *Daphnes*. (Silver Flora Medal.)

Mr. H. BURNETT, Guernsey, again exhibited remarkably choice flowers of perpetual-flowering Carnations, having splendid blooms of *R. F. Felton*, *Britannia*, *Mrs. H. Burnett*, *White Eucharist*, *Dorothy Gordon*, and other popular varieties. (Silver Flora Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, staged a large exhibit of Ferns in variety. *Platycentrum grande* was especially fine. The "sheaths" or sterile fronds are produced on alternate sides, at intervals, the older ones decaying in the centre. Other kinds shown well included *Pteris cretica* Childsii, *Platyloma rotundifolia*, *Hymenodium crinitum*, *Gymnogramma grandiceps superba*, *Davallia splendens*, *D. canariensis pulchella*, and *Asplenium grande*. (Silver Banksian Medal.)

Messrs. J. CHEAL & SONS, Crawley, showed a rock-garden exhibit, backed by dwarf Conifers and shrubs, and planted with *Primula denticulata*, Tulips, Primroses, *Iris alata*, *L. Danfordiae*, *L. reticulata*, *Erythrinum Hartwegii*, *Primula rosea*, and other early flowers. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, showed bulbous and other early flowers, including Crocuses, Irises, Scillas, Cyclamens, Snowdrops, *Adonis amurensis*, *Lachenalias*, and *Freesias*. There were varieties of shrubs in bloom, arranged as a setting to the other subjects, *Coronilla glauca* being conspicuously good. (Silver Banksian Medal.)

Other exhibitors of early hardy flowers were Messrs. T. S. WARE, LTD., Feltham (Bronze Banksian Medal); the Misses HOPKINS, Mere Gardens, Shepperton; and Mr. REUTHE, Hardy Plant Nursery, Keston, Kent.

Messrs. BEES LTD., Mill Street, Liverpool, showed a batch of plants of a white-flowered form of *Primula malacoides*.

Messrs. W. WELLS & CO., Merstham, showed two late varieties of single Chrysanthemums in

Kathleen May (chestnut red) and Edgar Forbes (rosy-mauve on a white ground).

AWARD OF MERIT.

Adiantum Farleyense *Glory of Moordrecht*.—An Award of Merit was granted to *Adiantum* *Glory of Moordrecht*, which is stated to be a variety of *Adiantum tenerum* *Farleyense*, raised from spores. See leading article on the subject, together with illustrations, p. 72, figs. 38, 39, 40.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), Sir Jeremiah Colman, Bart., Henry Little, W. Thompson, F. Sander, C. H. Curtis, J. Cypher, W. P. Bound, H. G. Alexander, W. Cobb, A. Dye, W. H. White, Gurney Wilson, R. G. Thwaites, J. Wilson Potter, W. Bolton, and de Barri Crawshaw.

Messrs. CHARLESWORTH & CO., Haywards Heath, were awarded a Silver-gilt Banksian Medal for a very fine group, the centre of which was composed of a large number of finely-flowered white *Lælia anceps*. But the attraction in the group was from the presence of several new hybrids, the most remarkable of which was *Odontoglossum Harwoodii*, a new cross with *O. maculatum auriferum*, and which secured a First-class Certificate, Awards of Merit being given to *Odontoglossum Marie* and *Miltonia Warszewiczii picta*. (See Awards.) At one end was a batch of brilliantly-coloured *Odontiodas*, *O. Diana* being of a bright rosy-crimson and rather larger than *O. Charlesworthii*. *Odontoglossum Doris*, with its fine flowers, evenly spotted with claret colour, was prominent in a batch of hybrid *Odontoglossums*; *Cattleya Octave Doin* and *Lælia-Cattleya Bella alba* showed up well in their respective sections. Throughout the group were various uncommon species.

Lieut. Col. Sir GEORGE L. HELFORD, K.C.V.O., Westonbirt (gr. Mr. H. G. Alexander), showed a small selection of fine Orchids, and three of these received Awards. A pretty novelty was *Brassia-Cattleya Euterpe* (*C. Schilleriana* × *B. C. Digbyana-Mossiae*), a very compact, rosy-lilac flower, with greenish-primrose disc to the fringed lip; and *Cattleya Sulla*, a promising hybrid of *C. Mendelii*. Also three cut spikes of the large white *Cologyne Moorei*, with seven and eight flowers, like white *Lælia anceps*; and sprays of *Vanda Watsonii*, also white.

Messrs. SANDEE & SONS, St. Albans, were awarded a Silver Flora Medal for a very interesting group, in which were *Coryanthes Balfouriana*, with clear, apricot-yellow flowers; the singular little *Lælia Lundii*, with pale, lilac flowers, veined with purple on the lip; *Dendrobium bellatulum*; *D. tetragonum*; a selection of handsome *Cattleyas*, including a good white *C. Trianae*, and some finely-coloured *C. Octave Doin*; *Maxillaria elegantula*; *Oncidium splendidum*, &c. Among the *Cypripediums* the finest was *C. Leeannum Thunderer*, a massive flower, and a very close ally of the famous *C. Leeannum J. Gurney Fowler*. The dorsal sepal is very broad and of thick substance, clear white, with a small apple-green base, and some rose-purple spots. The broad petals and lip are margined with primrose-yellow and tinged with purple.

H. S. GOONSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), was awarded a Silver Flora Medal for an effective group, in the centre of which was a fine specimen of *Cymbidium Lowi-grandiflorum*, and with it the brilliantly-coloured *Odontioda Cooksoni* Royal Scarlet, and a very handsome *O. Lutetia*; three examples of the purple-spotted *Odontoglossum ardentissimum* Herbert Goodson; and among other good *Odontoglossums* a pretty, new, rosy-lilac hybrid, with darker spots, and which had not yet attained its full size. *Cypripedium Minos Youngii* and other *Cypripediums*, and *Brassia-Cattleyas* were also shown.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged a very attractive group of rare *Cypripediums*, for which a Silver Banksian Medal was given. The new *C. Duke of Connaught* gained an Award of Merit (see Awards), and *C. Beryl splendens*, a fine flower, with much of the rose-purple colouring of the *C. Mrs. Wm. Mostyn* parent in the dorsal sepal; *C. Admiral Wilson* (*Ville de Paris* × *Leeannum*), a very pretty and effectively-marked flower; *C. insignis Burnside* variety; *C. Euryades* New Hall Hey variety;

varieties of *C. aureum*, *C. Helen II.*, *C. Beekmanii*, and others were finely shown.

Messrs. J. CYPHER & SONS, Cheltenham, were awarded a Silver Banksian Medal for a group of fine *Cypripediums*, the showiest of which were *C. Beekmanii*, *C. Thompsonii* (with bright, purple colouring in the white dorsal sepal), *C. Lathamianum aureum*, *C. Minos Youngii*, *C. Leeannum Sylhetense* (a large and very distinct flower), *C. Alcibiades superbum*, and some very pretty unnamed seedlings.

Messrs. STUART LOW & Co. showed a good group, for which a Silver Banksian Medal was awarded. In it were noted a good selection of hybrid *Cypripediums*, *Epidendrum Cooperianum*, various *Cattleyas*, including *C. Euid* and *C. Percivaliana alba*; some *Brasso-Cattleyas*, *Lycastes*, *Vanda Amesiana*, and *Saccolabium giganteum*.

Major ROGERSON, Heatherdale, Spencer Road, Harpenden, showed a group, in which were good varieties of *Cypripedium aureum*, including the yellow and white variety *Surprise*; also *C. Leeannum Charles Rogerson*, a very distinct form; *C. Boadicea magnificum*, fine in shape and colour; *C. Lillie Mayall*, a pretty hybrid; and among other famous varieties *C. Eison giganteum*. A good *Cattleya Trianae alba* was also shown.

JOHN S. MOSS, Esq., Wintershill Hall, Bishop's Waltham (gr. Mr. C. Kench), sent a fine specimen of *Odontoglossum nevadense* with several spikes.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), exhibited *Cypripedium Mary Beatrice* of a bright-red colour.

Mr. E. V. Low, Vale Bridge, Haywards Heath, sent *Cattleya Trianae Goliath*, a large and very broad-petalled form.

Messrs. HASSALL & Co., Orchid Nursery, Southgate, sent *Cypripedium Beryl* in excellent condition and with three fine blooms.

Messrs. HEATH & SONS, Cheltenham, staged a small selection of *Cypripediums*.

Captain HOPE, R.N., St. Mary's Isle, sent a spike of *Arachnanthe Maingayi* brought by him from Singapore some years ago.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum crispum Peacock, from Lieut.-Colonel Sir GEORGE L. HOLFORD, K.C.V.O., Westonbirt (gr. Mr. H. G. Alexander).—A chastely-beautiful, pure-white flower with bright reddish-rose blotches on all the segments, the two lower sepals having one irregular blotch, the upper one several smaller ones, in addition to the large blotch and the broad-

Cattleyas, and of fine substance. Sepals broad, greenish-white, tinged with lilac; petals and fringed lip pale rosy-lilac with greenish-primrose disc to the lip.

Odontoglossum Maria (Uro-Skinneri × Queen Alexandra), from Messrs. CHARLESWORTH.—A neat flower with greenish sepals and petals spotted with purple, and broad, white lip with rose-purple spots.

Miltonia Warscewiczii picta, from Messrs. CHARLESWORTH.—A remarkably beautiful form with branched spike of well-rounded flowers. Sepals and petals light brown tipped with yellow. Lip broadly ovate, dark rose, with pure-white front.

Cypripedium Duke of Connaught (Beryl × nitens G. S. Ball's variety), from Messrs. ARMSTRONG & BROWN, Tunbridge Wells.—A very distinct *Cypripedium* with the general characters of *C. Beryl*, but with a clear, greenish, Indian-yellow ground colour, the flat dorsal sepal having a narrow white margin and some dark chocolate-purple spots, the petals and inside lip being also spotted.

CULTURAL COMMENDATION.

To Mr. H. G. Alexander, Orchid grower to Lieut.-Colonel Sir GEORGE L. HOLFORD, K.C.V.O., for a compact and finely-grown plant of the large and finely-coloured *Laelia anceps Chamberlainiana* with 10 spikes bearing together 21 flowers (see fig. 41).

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq. (in the Chair); and Messrs. J. Cheal, G. C. A. Nix, W. Bates, A. Dean, E. Beckett, J. Vert, H. Markham, J. Jaques, G. Wythes, W. Poupard, J. Harrison, H. Somers Rivers, A. R. Allan, J. Parr, J. Davis, G. Reynolds, J. Lyne, and O. Thomas.

It was resolved, on the proposition of the Chairman, to send a vote of sympathy to the widow of the late Mr. George Hobday.

A few seedling Apples of no special merit were shown for award.

Messrs. J. CHEAL & SONS, Crawley, staged a collection of 54 dishes of well-preserved Apples. There were excellent fruits of (dessert) Castle Major, Peasgood's Nonesuch, Bramley's Seedling, Lane's Prince Albert, Lord Derby, Newton Wonder, Jubilee, Stirling Castle, King Edward, Niton House, Bismarck, Encore, and Sandringham; (culinary) Barnack Beauty, Adams's Pearmain, Buxted Favourite, Edmund Jupp, and others. (Silver Banksian Medal.)

Messrs. SUTTON & SONS, Reading, staged a collection of finely-matured and well-kept Onions, set up in 18 dishes or groups. Their selected Ailsa Craig was the dominant variety, the bulbs being of perfect form and very solid. Other varieties were Improved Reading (a somewhat flat-bulbing variety), Al. Medium Round, Coconut, and Long Keeper (a solid, globular Onion, of deep, reddish-brown exterior, and most distinct). (Silver Banksian Medal.)

LINNEAN SOCIETY.

JANUARY 19.—The President alluded to the great loss biological science had sustained in the death of Sir Francis Galton, F.R.S., on the previous day, and stated that although not a Fellow of the Society, he had often been at the meetings, and he was one of the recipients of the Darwin-Wallace Medal on July 1, 1908.

A paper was given by Mr. C. H. Wright, A.L.S., on the "Flora of the Falkland Islands." He stated that the paper was based upon a collection made by Mrs. Rupert Vallentin, whose father (Mr. W. Wickham Bertrand) was one of the earliest settlers in the West Falklands, but has been expanded to enumerate all the plants recorded from the Falklands. An endeavour has been made to define the distribution of plants in the islands and to show what changes have taken place in the flora since the publication of the *Flora Antarctica* in 1847. The plants are chiefly of dwarf habit, often with aromatic leaves, and conspicuous, often scented flowers, which are produced chiefly between November and January. The earliest to appear is *Draba faniculosa*, Hook. f., in September. The extermination of the fox (*Canis antarcticus*) has rendered possible the keeping of sheep, with the result that plants

FIG. 41.—*LAELIA ANCEPS CHAMBERLAINIANA* FROM SIR GEORGE HOLFORD'S COLLECTION.

(Awarded a Cultural Commendation on Tuesday last.)

EDWARD ROBERTS, Esq., Park Lodge, Eltham (gr. Mr. Carr), staged a group of *Cypripediums*, among which good *C. Sir Redvers Buller*, *C. aureum Pomona*, *C. St. Alban*, and *C. Victor Cavendish* were noted.

SAMUEL LARKIN, Esq., The Ridgeways, Haslemere (gr. Mr. Hale), staged a varied group, including *Cattleya Octave Doin Larkin's* variety, with a good, broad, rosy-crimson lip; *Cattleya Trianae alba* and *C. T. Edith Noel* (a lilac-tinted, broad-petalled flower, with a fine, rose-purple lip); varieties of *Cypripedium aureum*, and other *Cypripediums*, and *Laelia anceps Sauderiana*.

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), showed a spike of a very interesting cross between *Epidendrum nemorale* and *Cattleya Warscewiczii (gigas)* as *Epi-Cattleya nemorale gigas*. The flowers were elegantly disposed on an upright spike; in form, nearest to *E. nemorale*, but of good size, white, tinged with lilac, the ovate front of the lip veined with purple.

WILLIAM THOMPSON, Esq., Walton Grange (gr. Mr. Stevens), sent *Odontoglossum Clytie (Edwardii × Pescatorei)*, a pretty flower with white ground effectively spotted with claret colour.

fringed petals, a series of confluent blotches all more or less reniform when grouped. The fringed lip had a chestnut-brown blotch in front of the yellow crest.

Odontoglossum Harwoodii (× Wigianium × maculatum auriferum), from Messrs. CHARLESWORTH & Co., Haywards Heath.—A sterling novelty, and quite a new break, the yellow tint of Messrs. CHARLESWORTH'S *O. maculatum auriferum* blending in the bright yellow of *O. Wigianium* and resulting in the hybrid in a clear buttercup-yellow ground colour with lighter tint in the central area of the broad sepals and petals, the inner parts of which are spotted with dark claret colour, the petals having broad basal lines of the same colour. An incomparably better flower than the other *O. maculatum* cross, which was one of the attractions of the last Ghent Quinquennial Show, and one of the most distinct since the advent of the coveted *O. Smithii*, now in Mr. J. Gurney Fowler's collection.

AWARD OF MERIT.

Brasso-Cattleya Enterpe (C. Schilleriana × B. C. Dighyano Mossie), from Lieut.-Colonel Sir GEORGE L. HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander).—One of the best-shaped *Brasso-*

previously common have now become rare; amongst these are the Tassac Grass (*Poa flabellata*, Hook. f.), Cinnamon Grass (*Hierochloa redolens*, R. Br.), and Blue Grass (*Agropyron repens*, Beauv.). *Primula farinosa*, var. *magellanica*, Hook. f., while still abundant, is much dwarfed in those islets where sheep have been introduced. *Veronica elliptica*, Forst. f., attains a height of 7 feet, and is the tallest plant on the islands the next being *Chilotrichum amelloideum*, Cass. (the Fächima plant). *Azorella caespitosa*, Cav. (the Balsam-bog), forms hard masses up to 10 feet long and 4 feet high, which rapidly decay on being wounded. The flora shows a great affinity with that of Magellan and Chile.

Dr. Rendle and Dr. Stapf contributed to the discussion which followed, and Mr. C. H. Wright replied.

MANCHESTER AND NORTH OF ENGLAND ORCHID

JANUARY 19.—*Committee present*: Messrs. Ashworth, Arthur, Cowan, Cypher, Holmes, Keeling, Parker, Stevens, Thorp, Ward, and Weathers.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged about 500 plants of *Cypripedium* in a most pleasing manner. The range of variety was very extensive, and the plants generally had a clean and healthy appearance. (Gold Medal.)

J. H. CRAVEN, Esq., Keighley (gr. Mr. Corney), exhibited the rare *Odontoglossum crispum* var. *Solum*, which, however, was not shown in the finest condition.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Brown), exhibited *Cypripedium* × *Curtmannii*, West Point var. This fine variety received a First-class Certificate; another good plant in the same collection, viz., *C. × Moonbeam*, West Point var., was granted an Award of Merit.

E. BOSTOCK, Esq., Stone, Staffordshire (gr. Mr. Ballance), received an Award of Merit for *Cypripedium* × *Hector*, a pretty hybrid, the parents of which were not recorded.

JAS. WALMSLEY, Esq., Helmsford, exhibited a few hybrid *Cypripediums*, all raised from seeds of the same pod, but showing great variation.

W. R. LEE, Esq., Heywood, staged a group for which five points were awarded; several good plants were noticed, including a good form of *Odontoglossum crispum*.

Mr. H. ARTHUR, Blackburn, staged a pretty exhibit in the "small amateur" section, and was awarded a Silver Medal.

G. S. BALL, Esq., Burton, Westmoreland (gr. Mr. Herman), was awarded a Silver Medal for a group of mixed plants, which included an unusually fine inflorescence of *Angraecum sesquipedale*.

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), received an Award of Merit for *Odontoglossum* × *amabile* var. *Andrey*; Mr. WARD also exhibited a good form of *O. × Wilkeanum*.

Messrs. CYPHER & SONS, Cheltenham, were awarded a Silver Medal for a good collection of *Cypripediums*.

J. McCARTNEY, Esq., Bolton (gr. Mr. Holmes), exhibited a collection of *Cattleyas* and hybrids, for which a Silver Medal was awarded.

Messrs. SANDER & SONS, St. Albans, had a showy display of choice plants, one particularly noted being *Cypripedium* × *Charles Sladdin*.

Other exhibitors included Messrs. E. V. Low, Hayward's Heath; J. ROBSON, Altrincham; O. O. WRIGLEY, Bury; W. SHACKLETON, Bradford; S. H. LOW, Enfield; J. BIRCHENALL, Alderley Edge; and A. J. KEELING & SONS.

BRITISH GARDENERS' ASSOCIATION.

At the last meeting of this association, held at the R.H.S. Hall, Westminster, 44 new members were elected, bringing the total up to 2,008. An important meeting of the association was held at Birmingham on January 21; Mr. Udale presided, and about 90 gardeners were present. The secretary, Mr. J. Weathers, and Mr. Ratfill addressed the meeting. The proceedings were marked with great enthusiasm, and many present banded in forms of membership. Another meeting will be held at Birmingham on February 11, at the Cobden Café, when the local branch will be re-organised.

Obituary.

THOMAS DUFF.—We regret to record the death, on January 23, of Mr. Thomas Duff, until about nine years ago, gardener at Kenmore Castle, Kirkeudbrightshire, a post he had filled for about 50 years. Mr. Duff was also estate manager at Kenmore, and he retained this post on relinquishing his duties as gardener. During his tenure as gardener, the fine grounds at Kenmore Castle were maintained in excellent order. Mr. Duff leaves a widow and grown-up family, for whom much sympathy is felt in the district. The funeral was attended by representatives of the public bodies and benevolent societies with which Mr. Duff was connected.

HENRY HAMMOND GEORGE.—We learn with regret of the death, on January 25, of Mr. Henry Hammond George, second son of Mr. James George, horticultural sundriesman, Putney. The deceased, who was 45 years of age, was well known amongst horticulturists in the southern counties.

JOHN J. GORMLEY.—We learn from our American contemporary, *Horticulture*, of the death of Mr. John J. Gormley, of Messrs. Canger & Gormley, Chicago. Deceased was a native of Ireland, and, when 12 years of age, entered the service of his uncle, John Gormley, at Boston, who was one of the leading florists of that city. He removed to Chicago, and for many years was manager for Messrs. E. Weinbacher Co., engaging in business for himself about seven years ago. He was considered one of the most expert floral decorators in Chicago.

DEBATING SOCIETIES.

ALTON HORTICULTURAL.—At the meeting of the association held on Thursday, January 19, Mr. W. Yates, of Rotherfield Park Gardens, Alton, gave a lecture on "The Cultivation of Hardy Fruits, with special reference to the Apple." There was a good attendance and the President, Mr. H. P. Burrell, occupied the chair. Mr. Yates dealt with the planting and pruning of the trees, the gathering and storing of the fruits, also of transplanting, root-pruning, and other items of culture. He demonstrated the methods of pruning different varieties of Apple trees, and exhibited branches of sorts which fruit on the ends of the shoots.

NEWDURY AND DISTRICT GARDENERS.—The Mayor of Newbury presided at the meeting of the association held on Monday, January 16. Mr. Honage Wright delivered a lecture on "The Sweet Pea." Mr. Wright dealt at considerable length on the best varieties to grow, and how to treat them in different soils. He gave the following advice: Plant thinly, trench deeply, water freely, stake quickly, mature liberally, and remove the seed pods promptly.

CROYDON & DISTRICT HORTICULTURAL.—At the meeting held on January 17, Mr. H. Langford, Beckenham, lectured on "Chrysanthemum Growing." The lecturer recalled the enormous plants bearing over 100 blooms seen in his early career. He said those now in favour bear about a dozen blooms of good quality, and are grown either in pyramid shape or as stand rods.

WARGRAVE AND DISTRICT GARDENERS.—The annual meeting was held on January 11. Mr. T. Tunbridge was elected chairman, and Mr. F. Gray vice-chairman for the ensuing year. The annual report and financial statement were considered very satisfactory and adopted. At the previous meeting the chairman, Mr. Tunbridge, gave a paper on "Winter and Spring Bedding," in which he described the flowers and plants suitable for this kind of gardening, suitable combinations of plants for effect, the best means of preparing the ground, and different methods of propagating the various subjects.

GUILDFORD AND DISTRICT GARDENERS.—A meeting was held on Tuesday, January 24; Mr. G. Johnson presided over an attendance of 51 members. Mr. Shrivell, of the horticultural experiment station, addressed the meeting, and in the course of his remarks said that he had been carrying on experiments at his farm near Tonbridge, Kent, in conjunction with Dr. Bernard Dyer. These experiments were undertaken to determine whether large quantities of dung produced more economical results than smaller quantities in conjunction with chemical fertilisers, when used on various market-garden crops. The chemicals used were nitrate of soda, phosphates, and potash. The lecturer said that plants of the Cabbage tribe could be grown with chemical manures without dung, a mixture of 14lbs. of super-phosphate and 10lbs. of kainit per 100 square yards should be thoroughly mixed with the soil—later a top dressing of 5lbs. nitrate of soda should be given directly after planting, and a further 5lbs. about a month later. The lecturer recommended nitrate of soda in the kitchen garden, and said that one cwt. of this salt contains as much nitrogen as a ton and a half of rich farmyard manure.

BIRMINGHAM GARDENERS.—The inaugural meeting of the spring session of the association was held on January 23. Mr. C. H. Herbert (the vice-chairman) presided over a good attendance of the members. The essayist was Professor G. S. West, M.A., D.Sc., of the University, Birmingham, his subject being "Peach-leaf Curl or Blister as an Example of how a Plant may be Successfully Treated." The lecturer's remarks were illustrated by means of lantern slides. Professor West commented upon the erroneous

ideas concerning this disease, which has such a wide-spread belief amongst gardeners, pointing out that such ideas were the result of ignorance of the nature of the disease, and of the means of prevention. A short account was given of the geographical distribution of the disease, and New Zealand was mentioned as the country which has perhaps suffered more than any other from Peach-leaf curl. Professor West said that for some years previous to 1891, the loss to Peach growers in the United States of America from this disease was estimated at more than 3,000,000 dollars. The direct cause of the disease is a parasitic fungus. The life-history of *Tylococcus deformans*, the fungus causing the disease, was fully described.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 23, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather.—Rain fell on several occasions in Scotland and also in the south-west of England and the north of Ireland, but the quantity was generally slight. In other parts of the United Kingdom the weather, although often very cloudy, and in many places foggy, was mostly dry and occasionally fine and bright.

The temperature was above the average, the excess amounting to about 4° in some of the northern and north-western districts. The highest of the maxima were recorded on the 25th and 26th, and ranged from 59° in Ireland S., and 56° in England E., and the Midland Counties to 50° in Scotland N. The lowest of the minima, which occurred in most places during the earlier half of the week, ranged from 25° in England N.E., and 26° in the Midland Counties and Ireland S., to 32° in Scotland N., and to 37° in the English Channel. The lowest readings on the grass were 20° at Tunbridge Wells, 21° at Dublin, 22° at Crathee, Rauceby, and Hereford, and 23° at Kew.

The mean temperature of the sea.—On almost all parts of the coast the water was warmer than during the corresponding week of last year. The greatest difference being about 5° at Kirkwall and Teelin. The means for the week ranged from 48° at Scilly, 47° at Plymouth, and 46½° at Port Erin and Salcombe to 40° at Margate and Peninn Bay, 39° at Burnmouth, and 38° at Cromarty.

The rainfall was less than the normal in all districts: in eastern, central, and southern England the fall was less than 0.1 inch. At many stations the week was rainless.

The bright sunshine was below the average except in England S.E. and Ireland S., the deficit in the western and northern districts being large. The percentage of the possible duration ranged from 21 in England S.E., and 23 in England E. and Ireland S. to 6 in Ireland N., 5 in Scotland E., and 4 in Scotland N.

THE WEATHER IN WEST HERTS

Week ending February 1.

The best nineteen days for more than three years. The first three days of the week were very warm for the time of year, but since then the weather has been getting gradually colder. On the two warmest days the temperature in the thermometer screen rose respectively to 53° and 52°, whereas on the coldest day it did not rise higher than 36°. On the last night of the week the exposed thermometer registered 22° of frost—making this the coldest night as yet this winter. The ground is now at an average temperature at 2 feet deep, but 2° colder than is reasonable at 1 foot deep. No rain worth mentioning has now fallen for 19 days—making this the longest period with as little rain since September, 1907. That is to say, nineteen consecutive days with a total rainfall of only five-hundredths of an inch. For nearly a fortnight there has been no measurable percolation through either of the soil gauges. The sun shone on an average for 3 hours, 39 minutes a day, which is twice the average daily duration of bright sunshine at the end of January, and yet there were three days which were altogether sunless. On the last day of January the sun shone for 7 hours, 33 minutes—making this the sunniest day I have yet recorded here in that month. The wind was high on the first two days of the week, but since then light airs and calms have mostly prevailed. The mean amount of moisture in the air at 3 o'clock in the afternoon fell short of a seasonable quantity for that hour by 5 per cent. There was a thick fog in Berkhamsted all day on the 29th ult., but on the Common there was, during the afternoon, comparatively little fog, and the sun was shining brightly. The double Snowdrop came first into flower in my garden in the spot selected for its observation on January 25, or exactly a fortnight earlier than its average date in the previous twenty-four years, and 22 days earlier than last year.

JANUARY.

A month of average temperature, with a light rainfall and a good record of sunshine.—Taken as a whole this was a January of average temperature. On the warmest day the highest reading in the thermometer screen was 53°, which is about the average extreme maximum for the month, and on the coldest night the exposed thermometer showed 14° of frost, which is the highest extreme minimum reading recorded here in January for 11 years. Rain or snow fell on 15 days, to the total depth of 1½ inch, which is about half the average fall for the month. Virtually the whole of the rainfall was deposited on the first 12 days of the month, after which there was no rain worth mentioning. The ground was at no time completely covered with snow. The sun shone on an average for 1 hour 57 minutes a day, or for 22 minutes a day longer than usual, and yet there were 14 days which were altogether sunless. This was the calmest January for 13 years, and in no hour did the mean velocity of the wind exceed 15 miles—direction W.S.W. The average amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by one per cent.

OUR UNDERGROUND WATER SUPPLY.

Since the Winter half of the drainage year began in October last the total rainfall has exceeded the mean for those four months by 2½ inches, which is equivalent to an excess of 51,350 gallons per acre in this district. In the same four months last year the rainfall was about the average. E. M., Berkhamsted, February 1, 1911.

CAMELIAS: *W. E. Farnyard* manure in the solid form is not suitable for Camellias, and liquid manure of this kind should only be applied in the cases of well-established plants previous to the flowering period. The use of farmyard manure in the making of a border might, for a time, appear to be beneficial in promoting a deep green colour in the leaves and stronger growth, but later the soil would be liable to get sour. A mulching of manure from a spent Mushroom bed after planting would retain moisture, and its use may be desirable, but for established plants it is not to be recommended. The soil covered by the mulch being unobserved might become too dry during the formation of the flower-buds and cause bud dropping. In getting the sites ready for planting it is advisable not to make the border up to its fullest extent, but to proceed as with a Vine border by making it in portions. Camellias will thrive in a soil that consists chiefly of peat, but peat is not recommended for durability. Rather select a soil composed of at least two-thirds of good fibrous turfy loam, such as the top spit of an old pasture, and one-third of tough peat and well-decayed leaf-mould from such trees as the Oak and Beech. To this soil some coarse silver sand should be added and a fair amount of charcoal. In every instance make the border firm; this is most essential. See that the border is well drained and that the surplus water will pass quite away from the roots of the plant.

CULTURE OF CRASSULAS: Crassulas may, as a rule, be cultivated with very little trouble. Being of a fleshy character and natives of a hot country (South Africa) they should be exposed at all times to full sunlight, and allowed plenty of fresh air on all suitable occasions. In common with other succulent plants, they require a good supply of water during the summer time when they are growing freely, but during winter water must be applied sparingly as they are then very liable to damping. Crassulas should be potted in well-drained pots in a mixture of sandy loam, with plenty of brick or lime rubbish. Most of the species and varieties are propagated readily by means of cuttings, which should be inserted in pots or pans of sandy soil; in some cases the cuttings should be inserted singly into thumb pots. The cuttings should be watered, and if the pots are stood on an open bench or shelf in a greenhouse, the plants soon form roots. Do not place the cuttings in a close case, as they are liable to damp off. The species usually cultivated in gardens include *Crassula falcata*, more generally known as *Rochea falcata*, which produces large corymbs of bright crimson flowers, very effective for greenhouse decoration, and lasting in a good condition for at least six weeks. Even when the plant is not in flower, the thick, glaucous leaves are attractive. *Crassula lactea* has white, star-like flowers which are produced during the winter, generally in January. A well-grown specimen is most effective. The plant should be grown in 6-inch pots, or even in large pans. *Rochea coccinea* and *Rochea jasminaea*—both more generally known as Crassulas—are fairly common in gardens, and were, at one time, largely grown for the London market. *R. coccinea* is a very useful plant for greenhouse decoration. In former years large specimens, some 3 feet high and as much through, were common in gardens. *Rochea jasminaea* is a dwarfier plant than *R. coccinea*, with an almost prostrate habit of growth. It produces handsome, white, Jasmine-like flowers, which pass to a reddish colour as they fade. *R. jasminaea* generally flowers about May or June.

GRAFTING RHODODENDRONS: *B. H. J.* Rhododendrons are usually grafted indoors during February, March and April. The stocks are previously established in small pots, and are placed in the propagating house two or three weeks before they are to be grafted, in order that the sap of the stocks may be in advance of that of the scions. The method known as

saddle-grafting is adopted. This consists of cutting the stock in the form of a wedge and making the scion fit it exactly, or, if the scion is smaller than the stock, then it is cut to fit the stock on one side. The scions are bound firmly to the stocks with raffia and wax, or clay may be used, though a plastic material is necessary in every case. The grafted plants are stood in a close case in a temperature of 65° to 70°, where they remain until the scions commence to grow. After this stage the cases are ventilated by degrees until the plants are eventually removed to an open stage in the same house, previous to hardening them off in a cold frame. The grafting should be done as low down on the stock as possible, and the scions should be selected from terminal shoots, which are not bearing flower-buds.

MOTOR MOWER: *W. C. H.* A machine such as you require may be obtained from makers of mowing machines. Scan our advertising columns.

NAMES OF PLANTS: *Saron.* 1. *Saxifraga decipiens*; 2. *S. trifurcata*; 3. *S. cameifolia* var.; 4. *S. Hostii*; 5. probably *Sedum sexangulare*; 6. *Saxifraga aizoon*.—*H. E. B.* *Picea excelsa* var.—*F. P.* *Crotons*: 1. *Laingii*; 2. *Sinitzinianus*; 3. *Aneitumensis*; 4 and 5, the numbers on the specimens were obliterated; 6. *ruberrimus*.—*G. B. M. R.* It is impossible to name the plant of which you send a drawing and description of a capsule only. If you will send the seed-pod, we will do our best to identify the plant.—*W. E. Batty.* 1. *Juniperus prostrata*; 2. *Cupressus Lawsoniana* var. *compacta*—*E. G. Watkins.* *Pinus insignis*, the Monterey Pine.—*Forreman.* 1. *Odontoglossum blandum*; 2. *Odontoglossum crispum* *xanthotes*.—*G. H. Colwyn.* 1. *Pernettya mucronata*; 2. *Garrya elliptica*.—*A. H. & Sons.* *Ureodina pendula* (amea) and *Eriobotrya japonica*.

PEACH SHOOTS DISEASED: *J. T.* The trouble is caused by a parasitic fungus, *Gleosporium*. Remove all diseased shoots and spray the trees with liver of sulphur.

PLANTS FOR EXHIBITING: *Cheltenham.* Your letter is very indefinite; we assume that you wish to know the best three specimen blooming plants and three specimen foliage plants for exhibiting. Much will depend upon the date of the exhibition, which you do not state. If for an ordinary summer show, the flowering plants might be selected from *Lyora Williamsii*, *I. Pilgimii*, *Clatendron Baltomi*, *C. fallax*, *Chironia exifera*, *Anthurium Scherzerianum*, *Acalypha hispida* (Sanderi), *Erica Cavendishiana*, and others; *Allamanda Hendersonii*, *Statice intermedia*, *S. profusa*, *Rondeletia speciosa*, *Eucharis grandiflora*, and *Lapageria rosea*. Suitable fine foliage plants include *Codiaeum* (Crotons), *Caladiums*, *Pandanus Veitchii*, *Dracena Victoria*, *Abrutilon Thompsonii*, *Aralia elegantissima*, *Alocasias*, *Anthuriums*, *Begonia Rex*, *Kentia Belmoreana*, and other Palms, tree and other large-growing Ferns.

PLUM SHOOTS DECAYED AT THE CENTRES: *W. F. B.* The decay has resulted from a fungus present at the roots. Expose as many of the roots as possible, and dust them thoroughly with sulphur.

PROPAGATING GENISTAS: *A. F. B.* You do not state which kind of Genista you wish to propagate. The hardy kinds are easily raised from seeds which germinate quickly and soon furnish good plants. The greenhouse *Cytisus*, *C. fragrans*, which is usually referred to as *Genista fragrans*, is best raised from cuttings. One of two methods of taking the cuttings may be adopted. In the one case, soft shoots a couple of inches long are taken during early spring and inserted in a compost of equal parts of loam, peat and sand. Four or five-inch pots are used, and the pots are plunged in a close and warm propagating case until roots are formed, after which the young plants are removed to a shelf near the roof glass in the same structure for a week or so. They are then placed in a cooler house. The second method is by means of cuttings of half-ripened wood, 2 to 3 inches long, inserted during July and

August. These are potted in a manner similar to the spring cuttings, but they are placed in less heat, and take several weeks longer to form roots. The strong-growing variety, *elegans*, is very difficult to root from cuttings, therefore it is grafted on stocks of the type. Ordinary side-grafting is practised in spring, and the plants are stood in a close and warm propagating case until the union is complete. It is very necessary for young plants of *Rhododendrons* to be kept growing freely: the shoots should be frequently stopped, in order that a good foundation may be laid for the future plant.

PROPAGATING HEATHER: *C. C.* Heather (*Erica cinerea*) and Ling (*Calluna vulgaris*) may be raised from seeds, cuttings and layers. Seed may be sown on the surface of a bed of peaty soil in a cold frame, or in boxes or pans filled with peaty soil. No covering of soil is necessary, but the bed or boxes should be kept shaded until germination takes place, in from two to three weeks from the time of sowing. When large enough to handle, the young plants may be pricked off in a bed of peaty soil, where they must be shaded from bright sunshine. It is doubtful whether you will be able to procure seed without saving it yourself, for it is not generally stocked by seedsmen. Cuttings are inserted during July and August, selecting young shoots not more than an inch long. These are dibbled thickly into sandy peat in beds or pots; the peat should be made firm and covered with silver sand. Those inserted in beds are covered with handlights, those in pots are stood in a close case or covered with bell-glasses until they are rooted. The following spring the young plants are placed in nursery borders for a year preparatory to their final planting. Layering is performed in spring; peaty soil is placed around the plants and the branches weighted down into it by means of stones. The layers are usually left 1½ or 2 years before they are removed from the parent plant. Propagation by seeds and cuttings is best for general purposes.

ROMAN HYACINTHS FAILING TO FLOWER: *G. J. B. & Co.* The bulbs are healthy and sound, but they do not appear of sufficient size to flower well. Such small bulbs should have been cultivated for another year in the nursery.

SEDIMENT IN HOT WATER PIPES: *D. B.* If you refer to the "fur," this would have little or no manurial value beyond that due to the carbonate of lime, of which it is mainly composed.

ST. DOMINGO CEDAR: *C. P.* The portion of veneer is probably a wavy grained piece of *Cedrela odorata* or an allied species. The *Guide to the Wood Museum at Kew* is at present out of print.

TULIPS FLOWERING UNSATISFACTORILY: *G. J. P.* The trouble is apparently due to some cultural error, which only those responsible for growing the plants can determine. The bulbs are of good size; they were firm and healthy, and they contain flowers in each case. The most probable causes of the failure are insufficient heat—a mild bottom heat and a close atmosphere are an advantage in early bulb forcing—and lack of sufficient moisture. The green colour low down in the leaves of the variety *Rose Gris de Lin*, for example, indicates too much exposure to light at too early a stage. For this comparatively dwarf grower at this season of the year a closed frame with bottom-heat of 70° and complete darkness would have resulted in longer stems and better flowers. One flower of *Rose Gris de Lin* is perfectly formed, though small, but it is developed too short in the stalk; the other gives the impression of having been chilled by either cold air or water. There are similar indications in all the varieties with the exception of *Prince of Austria*, which, while being a more vigorous grower, is possessed of the best-developed bulb. The conditions you name would have been suitable a month later.

AGRICULTURAL EDUCATION IN CANADA AND THE STATES.*

LIKE every other similar institution in this country, the University College of Reading has found the problem of agricultural education one of extreme difficulty. Though the success which has attended the efforts of our agricultural colleges is by no means inconsiderable, those who are responsible for agricultural education in England—no matter where that education is given—must be complacent indeed, if they are completely satisfied with their present several measures of success.

The reasons for the slow development of a thoroughly satisfactory system of agricultural education in this country are not far to seek.

The lack of such a system is to be ascribed in part to national characteristics, and in part to the advanced stage to which the

practice of agriculture has reached. It is not, however, our present object to attempt to indicate in detail the causes to which may be attributed the not-altogether ideal state of agricultural (and horticultural) education in Great Britain; but rather to call attention to the enterprise shown by the Council of University College, Reading, in sending a deputation to Canada and the United States, charged with the duty of drawing up a Report on Agricultural Education in those countries.

This course of action was rendered possible by the generosity of Mr. Leonard Sutton—to whom the idea as a practicable venture was due—and to Mr. Alfred Palmer.

Thanks to the liberality of these gentlemen, the Deputation, consisting of five members of Council and Academic staff of the College, were enabled to study in detail, and on the spot, the working of some of the most important agricultural institutions in Canada and in the United States.

The centres visited included The Macdonald College (Quebec Province), the Central Experimental Farm (Ottawa), the Ontario Agricultural College (Guelph), and the Universities of Cornell and Wisconsin.

The first part of the report deals in comprehensive manner with the kind of agricultural education which is given at each of these institutions.

We have no hesitation in saying that the facts presented in this part of the Report, though they, by the nature of the case, make no claim to exhaust the subject of American agricultural education, provide us in England with a "document" of the very greatest value. They demonstrate that in Canada, and in the States, people have passed the stage of disputation as to whether it is possible to teach agriculture, and have determined not only that it can, but also that it shall be taught. Moreover, as the statistics included in Part I. of the Report prove, Canada and the States are to-day backing that conviction by the investment in agricultural education of sums of money, compared with which those granted for a similar purpose in this country are miserably inadequate.

But in addition to the timely and detailed reference to these facts, which are known to all scientific agriculturists, the Report makes clear that the spending of vast sums on agricultural education and research is carried out in Canada and the States in no haphazard manner. The monies which are granted for agricultural instruction are granted with intelligence, and with the object of securing definite ends. As the Report makes clear, these things are easier of design and execution in a new country than in an old one: they are easier in a land where agriculture looms large in the public eye, than in one where other industries obscure its importance.

The Deputation is to be congratulated on its avoidance of the somewhat sterile course of chiding its fellow-countrymen, or this or that Department of State, and on concentrating its energies on the production of a lucid statement of fact. As a result of this line of action, Part I., though it offers no material for controversy, presents an unanswerable case for the more thorough organisation of agricultural and horticultural education in Great Britain and Ireland.

Part II. of the Report is, on the other hand, and by the nature of the case, bound to call forth a certain amount of criticism. Nevertheless, we are of opinion that the views put forward by the authors are sound. They deprecate any attempt at slavish imitation here of methods found to be excellent for Canadian and American conditions. They draw attention to the fact that the practice of agriculture in Great Britain is far in advance of that in N. America, and they emphasise the fundamental differences between the problems of agricultural education presented by this country and those of Canada and the States; differences due to national temperament, climate and phase of development.

Among the various important recommendations and suggestions contained in Part II., one, concerned with the method of agricultural education, deserves the most careful consideration. This suggestion is to the effect that it is desirable to modify in a drastic manner, the curriculum generally in vogue in our agricultural colleges. The proposed modification consists in the curtailment and change of character of the instruction in sciences bearing on agriculture—chemistry, botany, &c. which instruction it is customary to give during the early part of the agricultural course. The Report recommends that the education given in the first year or two of the college course should deal much more with practical agriculture, and much less with elementary science. The students should be obliged to demonstrate that they have a sound, practical knowledge of agricultural operations. Having done this, they should learn by means of special practical courses what the most capable men have to teach them on special agricultural topics—soils and manures, the treatment of disease, and so forth. Not till they have done all this should the students—and then only those who wish to train as experts, or who have leisure for a longer course of study—take up courses in such sciences as chemistry and botany. It should be pointed out that in coming to this decision as to what is the best type of curriculum, the authors of the Report are actuated by no antipathy to science. They recognise, indeed, its paramount importance, and are at pains to point out how agriculture has benefited and is benefiting by the discoveries in chemical and biological science. All they urge is that a college-trained student should be first of all a thoroughly practical agriculturist, and that should he fail of this, no amount of pure or applied science will avail him. If he is a practical agriculturist, the more science he has the better; if he is not, then his agricultural education is a failure, no matter how wide his book-learning may be, and no matter how high are his scientific attainments. Whether, however, he agrees with all the conclusions arrived at in the Report, no one can peruse it without being compelled to think seriously, both on the important subjects with which it deals and on the loss which is bound to befall this country unless it takes active and immediate steps to improve and develop its system of agricultural education.

Finally, we may add, that we are pleased to know that the origin of the expedition, which the Report records, was due to the initiative and generosity of one of the most prominent of British horticulturists.

* Report of a deputation, appointed by the Council of University College, Reading, to visit selected centres of agricultural education and research in Canada and in the United States. (Published by University College, Reading, 1s.)

NEW OR NOTEWORTHY PLANTS.

PINGUICULA ROSEI.

ABOUT three years ago Kew received from the United States Department of Agriculture, Washington, a tiny plant which had been collected by Mr. Rose somewhere in Mexico. It grew into something very like *Pinguicula caudata*, having a *Sempervivum*-like cluster of leaves at first, and later much larger, tongue-shaped leaves, with incurved margins exactly as in *P. caudata*. When it flowered, we were at first disposed to call it a variety of that species, and botanically, perhaps, it is nothing more; but there are slight differences in the form of both kinds of leaves and a very decided one in the colour of the flower, which is deep violet-purple, almost a blue. On enquiring of Mr. Rose if he had any recollection of the plant as it grew wild in Mexico, or if he had seen it since in cultivation, he replied that he was uncertain about it. Anyhow, the plant is established at Kew, where it grows well and flowers freely in the warm Orchid house, and, for garden purposes, at any rate, it must have a distinctive name. Accordingly, we have called it *P. Rosei*, in compliment to its discoverer.

P. caudata is largely grown by Orchid breeders, who find it an excellent trap for the tiny midge-like fly which lays its eggs in Orchid seedlings when they are very young, and, if not kept in check, is capable of a good deal of mischief. Mr. Thompson, of Stone, was, so far as I know, the first to put this *Pinguicula* to this particular use, growing it by the hundred among his Orchid seedlings. It is a most charming little pot-plant, and has become a favourite in many gardens since its introduction from Mexico by Messrs. F. Sander & Sons in 1881. It was figured in *Gardeners' Chronicle*, 1881 (1) p. 541, under the name of *P. Bakeriana*. The flowers of *P. Rosei* are nearly 2 inches across, and they remain fresh on the plant for weeks. Both it and *P. Bakeriana* may be propagated from the small, fleshy leaves by setting them singly in a pot of silver sand and covering them with a bell glass. W. W.

NOTICES OF BOOKS.

JAMAICAN ORCHIDS.*

DURING a residence in Jamaica of 21 years as Director of Public Gardens and Plantations, Mr. William Fawcett devoted considerable attention to the botanical exploration of the island, and especially to the Orchids, of which, with the assistance of Mr. William Harris, Superintendent of the Gardens, he made a very fine collection. A series of drawings from the living plants was also made by Miss Helen Wood. On Mr. Fawcett's retirement and return to England, the permission of the Trustees of the British Museum was obtained for the publication of a work on the Orchids of Jamaica, and this has been carried out with the collaboration of Dr. Rendle, Keeper of the Department of Botany. It is proposed that the present volume shall form the first part of a complete *Flora of Jamaica*.

The Orchids of Jamaica are of special interest, from the large number of endemic forms, 73 out of an aggregate of 194 species being confined to the island, so far as at present known. There are 61 genera, one of which, *Homalopetalum*, is endemic. The most striking affinity of the Orchid flora is with that of the neighbouring island of Cuba, 82 of the 121 non-endemic Jamaican species being also found there, and 14 of them are not known elsewhere. Forty species are common to Jamaica and Trinidad, a similar number to Jamaica and

Flora of Jamaica, containing descriptions of the flowering plants known from the Island, by William Fawcett, B.Sc., and Alfred Barton Rendle, D.Sc., F.R.S., Vol. I. "Orchidaceae," 8vo., pp. 150, with 32 plates, and an introduction and index. Published by order of the Trustees of the British Museum. (Longman & Co.)

Porto Rica, and almost as many to Jamaica and one or more of the Lesser Antilles. The relationship with Central America is well marked, 37 Jamaican species being found in some part of Central America, or 44, if Mexico be included, and 48 species are common to Jamaica and tropical South America. It is interesting to note that a few species common to Central America and Jamaica are not known to occur elsewhere in the West Indies, and these are regarded as representing an element of the Jamaican flora associated with two former extensions of the land surface, between Cuba and Yucatan, and Jamaica and Honduras. How far opinion on these and some other anomalies that are discussed may be modified when other parts of the West Indies are better known remains to be seen.

FIG. 42.—PINGUICULA ROSEI: COLOUR OF FLOWERS, VIOLET.

Some very interesting details of the physical features of the island are given. It is 144 miles long by 30 to 40 miles broad, and is remarkable for the limited area in which very many species are found, and for the wonderful contrasts between neighbouring districts in geological structure and soil, elevation, rainfall and temperature. The Blue Mountains, at the eastern end of the island, attain an altitude of 7,423 feet, and here the north-east trade winds bring almost constant rain throughout the year, the rainfall varying from 150 to 200 inches annually. Toward the south coast the rainfall decreases, and there are belts with a rainfall of 70 to 55 inches, or 50 to 40 inches, and then for a considerable distance, to Kingston and beyond, of 35 to 30 inches annually. The John Crow or Blake Mountains, at

the east end of the island, are so wet, and the limestone rock so precipitous and difficult to travel over, that it is believed that only one white man has ever crossed them, and in such places new species may be yet discovered.

Of the 61 genera of Jamaican Orchids, *Epidendrum* occupies the leading position, with an aggregate of 31 species, being followed by *Pleurothallis* with 27, *Lepanthes* with 19, and *Habenaria* with 3, while as many as 28 genera have only a single Jamaican representative. *Lepanthes* seems to be a characteristic Alpine genus, and 17 of the 19 species are not known elsewhere, the other two being also found in the mountains of Cuba. This genus contains a high proportion of novelties. Two new genera are established, *Neourbania* and *Harrisella*, both monotypic, and common to Jamaica and Cuba.

Very few of the Jamaican Orchids are much cultivated in Europe, but among those that are grown may be mentioned the charming little *Laelia monophylla*, one of the endemic species, *Broughtonia sanguinea* and *B. domingensis*, *Schomburgkia Lyonsii*, *Brassavola nodosa*, *Oncidium luridum*, a few species of *Epidendrum*, *Brassia caudata*, and *B. maculata*, with a few others. The occurrence in Jamaica of the eastern *Phaius grandifolius*, now called *P. Tancarvillei*, is interesting, and we read: "This species cannot be considered indigenous, but it is so completely naturalised and so common in some parts of Jamaica that a full description has been included. It is also recorded from Cuba."

The work contains keys to the genera and species, full descriptions, references to existing descriptions and figures, and a detailed list of known Jamaican localities, with a brief indication of the range of the species elsewhere. Altitudes are also given. The arrangement followed is that of the late Professor E. Pfitzer, in Engler and Prantl's *Pflanzenfamilien*.

The plates are lithographic, from drawings by Miss H. A. Wood, and are largely devoted to analytical details, which will be invaluable to those engaged in studying the Orchids of Jamaica. The work, though concise, is carried out with great thoroughness, and forms a valuable guide to the Orchid flora of the island. R. A. B.

THE IMPERIAL DEPARTMENT OF AGRICULTURE IN THE WEST INDIES.*

(Continued from page 76.)

The cultivation of Sea Island cotton was introduced into the West Indies in 1903. The best seed was obtained from the Sea Islands by the Department, and numerous experiment plots were started to show successful methods of cultivation. In 1904 the area planted amounted to 7,600 acres. This steadily increased until 24,000 acres were planted in 1908. The total exports of Sea Island cotton (including a small supply of Marie Galante cotton from Carriacou) amount to 15,000,000 lbs., of the value, in lint and seed, of £300,000. Valuable assistance was rendered by the British Cotton Growing Association in making grants of money and machinery; also in taking charge of the shipments of cotton and finding the best market for them. It also provided the services of a travelling inspector to be attached to the Imperial Department of Agriculture in connection with cotton investigations. Sir Alfred L. Jones, President of the Association, offered 11 gold and 17 silver medals for competition among Cotton-growers in 1906-7. A visit of representative Cotton-growers from the West Indies was made to Lancashire in the summer of 1908, when they were most hospitably received at Liverpool and Manchester, and obtained valuable information for their guidance in dealing with future crops. It is admitted that if fine Sea Island cotton had not been obtained in appreciable quantity from the West Indies in recent

* Paper read by Sir Daniel Morris, K.C.M.G., D.C.L., D.Sc., F.L.S., at the Royal Colonial Institute, on January 10, The Right Hon. Lord Brassey, G.C.B., in the chair.

years, several of the cotton mills in Lancashire would have been compelled to work short time. This is an instance of the value of encouraging agricultural industries in our Colonies and the benefit arising to the Mother Country.

The exports of Limes, concentrated Lime-juice, and essential oils of Limes (obtained from the West Indian Lime-tree) from Dominica are of the annual value of £54,951; Lime-juice and oils are exported from Montserrat of the value of £7,500; Limes and Lime-juice from Jamaica to the value of about £6,000. Trinidad also exports some Lime-juice. There is an increasing demand for West Indian Limes in the United Kingdom. The West India Committee is rendering useful service in bringing Limes under the notice of the British public, and encouraging their more general use instead of Lemons.

The possibility of establishing rubber plantations in the West Indies has received careful

number of these distributed in the years 1901 to 1905 amounted to 621,007, and during the years 1906 to 1909 554,144, making a total of 1,375,151. In addition there were distributed large quantities of Sugar canes, sweet Potato slips, Cassava cuttings, Pine-apple suckers, Bananas, Plantains and large quantities of various seeds and Cacao pods. The distribution of these was accompanied by information for their treatment, and the growers were visited from time to time by the travelling agricultural inspectors. It is estimated that the plants distributed during the last ten years would be sufficient to establish areas equal to about 10,000 acres in Cacao or Oranges, or 20,000 acres in larger trees, such as Rubber; Cocoa-nuts, or Mangoes.

The Royal Commission of 1897 stated that "a system of training in agricultural occupation was much needed." A considerable amount of attention has been devoted to this subject during the

In reviewing the considerable progress that has been made in other Colonies, it was recently reported that in British Guiana over 50 schools have started small gardens and earned 80 per cent. of the grants offered. At Trinidad 203 schools were examined in practical agriculture, and school shows for plants and produce raised by the pupils are regularly held. At Barbados 44 schools presented children for examination in object-lessons connected with agricultural subjects. About one-third of the schools had small gardens, or showed plants under cultivation in pots and boxes. In the Windward and Leeward Islands fair progress has been made. The chief drawbacks there are the want of carefully-trained teachers and the small encouragement offered in the Government codes for teaching agriculture and maintaining school gardens.

In the case of grants offered by the Department to agricultural shows, it was stipulated that a special class should be provided for plants and produce grown by children in the elementary schools. The result of this has been generally satisfactory.

The establishment of agricultural training schools by the Department at St. Vincent, St. Lucia, and Dominica, where selected boys of the agricultural class were boarded and trained for a period of three years, have clearly demonstrated the value of such practical training in raising the standard of cultivation and in spreading sound knowledge of the treatment of crops. About 70 students trained at these schools have already obtained employment as foremen and overseers, or are otherwise engaged in agricultural work.

At Jamaica a somewhat similar institution, known as a farm school, has lately been established under the auspices of the newly-created Department of Agriculture. It is stated that the applications for admission were so numerous that a large number of students had to be refused. The Director regards this as demonstrating that "there is a demand for agricultural education of a practical type in Jamaica, and that the people are willing to pay for it. . . . When we realise that six-sevenths of the lands alienated from the Crown in Jamaica belong to small proprietors, the magnitude of the public interest involved in grading up the agricultural operations of the people is at once apparent." The Director adds: "It is in the methods of permanent and intensive cultivation by the use of mixed farming and a combination of animal industry with crop production that the obvious progress of the people lies."

Agricultural teaching in secondary schools and colleges is making steady progress at Harrison College, Barbados, and at the Queen's Colleges at British Guiana and Trinidad and at Jamaica. Agricultural science is also taught at the grammar schools at Antigua and St. Kitts, and scholarships have been provided by the Imperial Department of Agriculture.

(To be continued.)

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM DUKE OF CONNAUGHT.

This distinct variety of *Cypripedium* (see fig. 43) was raised from *C. Beryl* and *C. nitens* G. S. Ball's variety. In its general characters it more closely resembles the first-named parent, but the colour is a clear, greenish, Indian-yellow, with spottings of a dark chocolate colour on the dorsal sepal, the petals and inside of the lip being also spotted. A narrow white band on the margin of the upper segment gives the bloom an additional pleasing feature. The variety was given an Award of Merit by the Orchid Committee of the Royal Horticultural Society on January 31, when it was exhibited by Messrs. Armstrong and Brown, Tunbridge Wells.

CALANTHES AT CAVENHAM PARK GARDENS, MILDENHALL.

MR. GEORGE HEATH, the gardener, has kindly forwarded a photograph (not reproduced) of a group of Orchids, chiefly *Calanthes*, taken a few days before Christmas in Cavenham Park Gardens. Many of the flower-spikes of the *Calanthes* were 4 feet in length, and carried more than 50 flowers each.

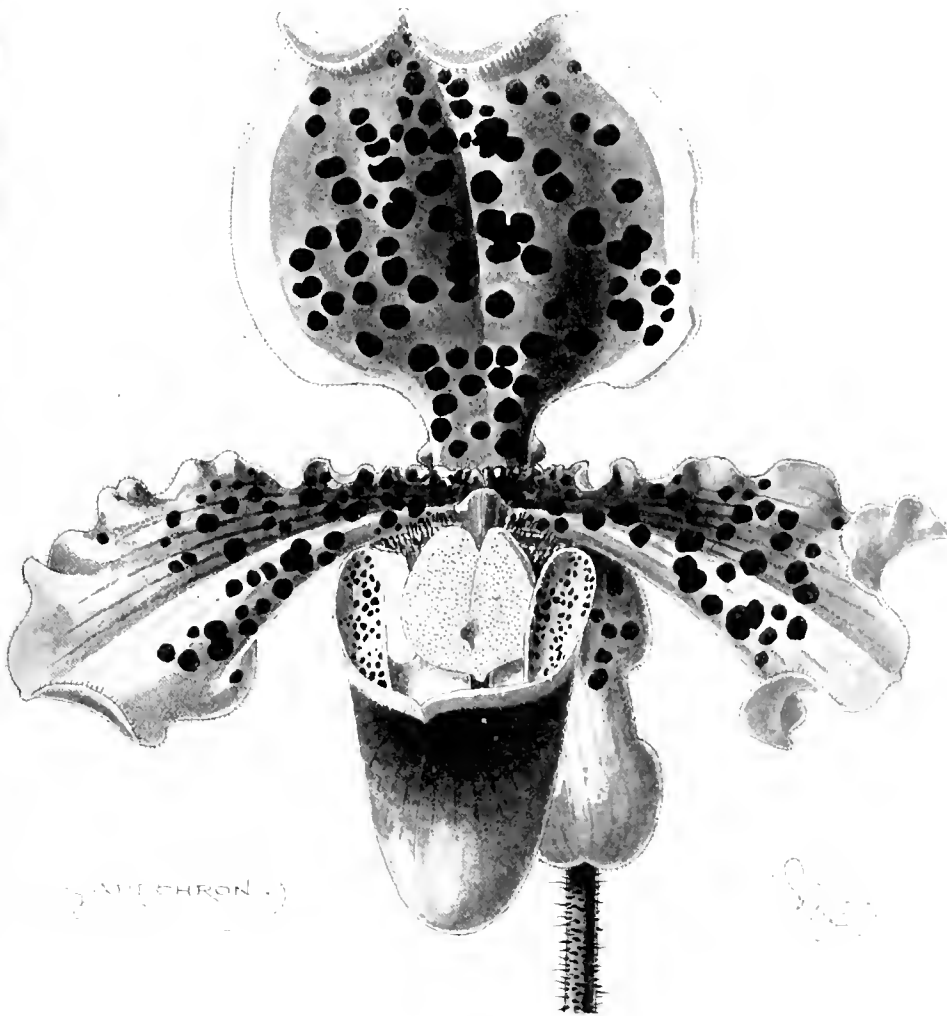

FIG. 43.—CYPRIPEDIUM "DUKE OF CONNAUGHT."
(Received R.H.S. Award of Merit on January 31.)

attention. There are 33 estates engaged in the industry in Trinidad and Tobago. Three experiment plantations are being established by the Government of British Guiana, and several concessions for land have been granted to public companies formed during the past year.

Rubber cultivation also is being established in British Honduras, where the central American Rubber tree, *Castilloa elastica*, is native.

An interesting part of the work of the Imperial Department of Agriculture has been the distribution of economic plants from the Botanic and Experiment Stations in the Windward and Leeward Islands and Barbados. These have consisted of established plants ready for planting of Cacao (from seed and grafted), grafted and budded Oranges and Grape fruit, grafted Mangoes, Rubber, Nutmeg, growing Cacao-nuts, Limes, Bay Rum, hedge and shade plants, &c. The

last ten years, with the result that probably no part of the Tropics is now more fully provided with the means for extending agricultural knowledge both among the growing members of the population or among the adult population. In the first instance, all teachers in charge of elementary schools were taken through successive courses of lectures and demonstrations in agriculture. They were afterwards supplied with school readers and a book of Nature teaching specially prepared for use in the Tropics. Jamaica may be regarded as having taken the lead in teaching agriculture in elementary schools, and by establishing annual courses of instruction to teachers in theoretical and practical agriculture at the Mico Institution and the provision of a staff of travelling agricultural instructors it has laid the foundation for an efficient scheme of agricultural education throughout the Colony.

FOKIENIA HODGINSII.

STRUCTURE OF THE WOOD.

The following notes upon the structure of the wood of *Fokienia Hodginsii* are based upon a portion of young stem, 4 inches in diameter, and showing 18 annual rings:—

The wood has the homogeneous structure of the family Cupressineae, being compact and even in texture, fine and fairly close in grain; and is moderately hard and firm. The colour is yellowish-white, tinged with pink; and no distinction between the heart and sap was observ-

outer periphery of each annual ring. The radial walls of the tracheids bear the usual conspicuous bordered pits, which, when seen on surface view (radial section), form a single row down the length of each tracheid. Each pit occupies about two-thirds of the total width of the tracheid. The tangential walls are only pitted in the case of the autumn tracheids, and on these walls bordered pits of a comparatively large size are more frequent than on the radial walls.

The medullary rays are almost invariably one cell wide, and vary from 1 to 20 cells in height, the average being 8 to 12 cells. Sometimes, as seen on tangential section, the cells become doubled about the middle of a ray. The tracheids adjoining the rays communicate with them by simple pits, which, in surface view, are seen on the radial wall as fairly conspicuous oval pits, lying somewhat obliquely to the long axis of the cell. In transverse and tangential sections these show a faint tendency to become one-sided bordered pits, the orifice of the pit being slightly narrower than the base. The horizontal walls separating one ray cell from another have simple pits, oval in surface view, with a wide-mouthed orifice, when examined in radial section.

The terminal (i.e., tangential) walls of the ray cells may be straight, oblique, or curved, but are rarely pitted or thickened, being usually very thin, about half the thickness of the horizontal walls.

The resin cells form longitudinal chains of cells, whose walls, both tangential and radial, bear simple pits.

Judging from Penhallow's* description of the wood of the Cupressineae, *Fokienia* seems more nearly related to *Cupressus* than *Libocedrus*. The thin terminal walls of the ray cells, the large numerous bordered pits on the tangential walls of the autumn tracheids, and the tendency of the rays to become two cells wide, connect the wood with *Cupressus* rather than with *Libocedrus*. On the other hand, the distribution of the resin cells in tangential bands is like that of *Libo-*

cedrus; but this character is, perhaps, not important, as the amount of resin varies enormously in different individuals of the same species, and appears to depend largely on conditions of growth. *E. R. Burdon, M.A., Cambridge.* [Mr. Henry asks us to state that fig. 32

FIG. 44.—FOKIENIA HODGINSII: TRANSVERSE SECTION OF WOOD.

r.w., radial walls; m.r., medullary ray; h.w., horizontal walls; spr. tr., spring tracheids.

able in the young stem examined. The annual rings average 3 mm. wide, the zone of "spring wood" occupying almost the entire ring, the "autumn wood" being confined to a very narrow zone, which forms a fine clearly-marked ring boundary. The medullary rays are exceedingly fine, .03 to .05 mm. wide, .1 to .15 mm. high; in cross-sections barely visible in the solid wood without a lens; while on the tangential surface their limits are quite indistinguishable even with a compound microscope; on the radial surface they form a silver grain of narrow inconspicuous yellow bands. The rays are not very regularly spaced, the number varying from three to eight per millimetre in cross section.

The most noticeable feature is the abundance of resin cells, which are far more numerous than in any species of *Cupressus* which I have examined. Usually in *Cupressus*, the resin cells are scattered and isolated in the annual rings, so that it is difficult to detect them without recourse to microscopical sections. In *Fokienia* they are so numerous that they can be detected at once by the naked eye. In transverse section, they are disposed in tangential bands, as many as four bands occurring in a single annual ring. In longitudinal section, the resin cells are visible either as rose-coloured streaks (radial section) or patches (tangential section), which impart a distinct tinge to the colour of the wood. With a lens, ruby-coloured granules of resin can be seen lying in longitudinal rows in the cells. The wood examined is devoid of smell, but it is possible that fresh specimens possess a fragrant odour, due to the resin, such as occurs in the wood of species of *Cypress*.

The bulk of each annual ring is composed of spring tracheids, with comparatively large lumina, about .03 mm. in diameter; while the autumn tracheids, with small lumina, are limited to a narrow zone, 3 to 12 cell rows deep, at the

The Week's Work.

THE KITCHEN GARDEN.

By JOHN DENN, Kitchen Garden Foreman, Royal Gardens, Windsor.

CELERY.—A small sowing of Celery may now be made in a house in which the temperature is 60°. The soil for this purpose should be made very fine, and the seed covered as lightly as possible. When the plants are large enough to handle, they should be pricked into boxes, or small pots, and kept close until they commence to make fresh growth, when air must be admitted. The plants should never be allowed to suffer for want of water.

BRUSSELS SPROUTS.—Sow seeds in boxes and place them in a temperature of 50° until the plants are through the ground, then remove them to a cool-house or pit, and gradually harden them off for pricking out in a cold frame. Cabbage may be sown and treated in the same way, so that young plants may be ready to put out as early in the season as possible. The same remark applies to Red Cabbage.

LEEKs. Make a small sowing of Leeks as soon as possible after this date, in order to obtain a few large stems early in the season. Sow the seeds thinly in boxes, and germinate them in a warm house. When the seedlings are well above the soil, place them close to the roof-glass in order to promote a sturdy growth. When large enough, they should be pricked out thinly into boxes filled with rich soil, or singly into small pots. For a few days after they have been disturbed, maintain a close atmosphere; but when they begin to grow again, afford fresh air freely, whenever the weather permits, so that the plants may be strong and hardy by the end of April, at which time they should be planted out-of-doors. As the Leek is a gross feeder, the trenches should be made some time in advance of the planting, and a liberal supply of manure placed at the bottom. If large specimens are required, a distance of 18 inches between the rows and 2 feet between the trenches should be allowed.

PARSNIPS.—The ground intended for this crop, having been trenched early in the winter, should now be dug with a digging fork, as soon as the soil is dry enough to permit of the operation. Break up the soil as finely as possible, and then allow it to remain undisturbed until it is dry enough to be levelled with a wooden rake. The drills should be drawn 18 inches apart, and the seeds sown thinly. If extra fine roots are desired, holes may be made with a crowbar to a depth of 3 feet and filled with finely-sifted soil. Sow a few seeds where each hole has been made, and when they have germinated, remove all but the strongest seedling. Soot and wood ashes make an excellent dressing for Parsnips.

JERUSALEM ARTICOKES.—Lift the tubers as soon as possible, selecting the largest ones for consumption, and those of a medium size for forming a fresh plantation. Plant the tubers in rows, at a distance of 18 inches apart, allowing 4 feet between each row. Select rich land for this crop in some secluded part of the garden.

SPINACH.—Make a sowing of summer Spinach as soon as the soil is in a workable condition. Provided a sheltered position is chosen, this sowing should afford a supply of leaves early in May. If sown in rows, make the drills 18 inches apart. Many growers, however, prefer to sow Spinach between rows of Peas or Broad Beans, and this system is a very good one, as the Spinach may be gathered and the plants cleared off before the other crops have matured. The plants of autumn-sown Spinach should have any decayed foliage removed, and the soil between the rows lightly disturbed with a fork, after which a dressing of soot should be applied.

MUSHROOMS.—Collect and prepare the materials for the making of fresh beds in order that a supply of Mushrooms may be maintained through the spring months. The manure should be placed in an open shed, and turned on every second day, during at least a fortnight. When it

is considered that fermentation has gone on long enough, the manure should be placed in the house in a layer about 2 feet thick. After remaining undisturbed for a day or two, and when the temperature has risen through fermentation to 85°, the litter should be turned over, and afterwards rammed together tightly. The bed should be spawned when the temperature has fallen to 80°. After a few days the surface of the bed should be covered with a layer of fresh loam, making it firm by beating it with a spade. Little further attention will be necessary for a month following beyond keeping the atmosphere of the house damp, and syringing the floor and walls occasionally. Beds in bearing should not be allowed to become excessively dry, and fire-heat should, as far as possible, be avoided. If a temperature of 55° can be maintained without artificial heat, there will be little need for moisture beyond that supplied by occasionally damping the walls with rain-water.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir C. J. HOLLIDAY, K.C.V.O., C.I.E., Westonbut, Gloucestershire.

WATERING.—This important detail of Orchid culture should always be performed with great care, but at no time in the year is this more important than at the present season, when many plants are just commencing to grow. When the pseudo-bulbous Orchids are finishing up their growths in late summer and autumn a liberal supply of water is required, even though the plants are apparently going to rest. The roots are then actively searching, as it were, for the moisture essential to build up a solid, sustaining pseudo-bulb, that will possess the rudiments, it may be, of the flowers for the following year, or, if the plants are late summer or autumn bloom-species, the vigour to carry them over the period of rest. But even at that season care must be taken not to promote an over-stimulating atmosphere in regard to heat. From the present time onwards, when these same plants are commencing to grow afresh, the treatment I have just described has, in a general way, to be reversed. The matured bulbs contain a considerable amount of stored nutriment, therefore, the roots are less active than they will become later. It will be seen that new growths nearly always appear before root-action is established, therefore water must be afforded only very moderately until the production of roots indicates that there is general activity throughout the plant. At that stage a moist atmosphere is essential. It should always be borne in mind that nothing so quickly injures young shoots of tender Orchids as lack of moisture in the air, and also that of excessive watering of the roots is disastrous.

ODONTOGLOSSUM HOUSE. The Odontoglossum house will become of greater interest each day. Most of the plants have made considerable progress since they were potted last autumn, and the roots have got into the new material. Such plants will now need more moisture, both at the roots and in the atmosphere, as their energies will be directed towards completing the pseudo-bulbs and developing their flower-spikes. Plants that are backward in growth, on the contrary, should still be watered sparingly, or the material may get soured and clogged. Maintain the atmosphere moist, and employ ventilation on all favourable occasions, but extra care is needed in admitting air, and observation must be made of the results upon the plants. As there are many tender flower-spikes now pushing forth, it will be necessary to keep a look out for slugs and snails. Popular baits include Lettuce leaves, slices of Potato and Carrot, and a little bran in small saucers placed about the house. If they are examined each night by lamplight, many of these pests may be destroyed. In regard to the choicer specimens, if a little cotton-wool is placed about the base of the flower-stems, it will preserve them from attack. Another good plan is to place the plant on an inverted pot, which is stood in a saucer of water; but, even if this is done, constant watch is necessary, for small slugs and snails are frequently hidden in the potting materials of the very plants it is wished to preserve.

BLINDS.—All blinds should at once be made ready for use, as the sun heat may be expected to show a considerable increase by the end of this month. Houses that contain *Cypripediums*,

Phalenopsis, *Odontoglossums*, *Miltonias*, *Masdevallias*, and other Orchids which have leaves of a soft texture, should be the first to be provided with blinds. For such houses the blinds should be made of a closely-woven, soft fabric. A similar material, but of a trifle lighter texture, may be used for houses containing species which are not injured by exposure to a strong light. All the blinds should be fixed on runners, placed at distances 9 inches from the glass, so that there may be a free passage of air between the plants and the roof-glass.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

PINEAPPLES.—Suckers of Queen Pineapples that were potted up last autumn should now be shifted into their fruiting pots. Use clean, well-drained pots of a large size, and cover the crocks with fibrous loam. The compost should consist of turfy loam with a good sprinkling of coarse road-grit, bone-meal and soot, and a little artificial manure. Water the plants some little time before they are potted to ensure the ball of soil being moistened thoroughly. Pot firmly and leave plenty of room for watering, as copious supplies of moisture at the roots will be required later in the season. Plunge the pots to their rims in a bed of leaves, made thoroughly firm and affording a bottom heat of about 80°. Maintain a humid atmosphere in the house by frequent dampings, and spray the plants on fine days. Water must be sparingly given in the pots until the roots have penetrated in the new soil. Maintain a night temperature of 65° or thereabouts according to the weather conditions. Suckers of other varieties that are large enough may be taken off and potted into 6-inch pots to form plants for successional fruiting. The pots should be plunged, and water must be carefully applied until the roots are active.

CUCUMBERS.—If Cucumbers are now planted in houses where a suitable temperature may be maintained, the plants may be expected to grow freely and provide quickly-grown, succulent fruits. I prefer planting Cucumbers on mounds of soil placed on a mild hotbed, composed principally of tree leaves and about one-third of long strawy litter. This should be brought into the house, and made thoroughly firm some time before planting. The soil may consist of good loam, with a liberal addition of leaf soil and coarse sand; the plants do not make such a rank growth in this compost as in one consisting entirely of loam and horse-droppings. Do not plant too firmly, and afford water, warmed to the temperature of the house, through a fine rose. Keep the foliage clean by frequent syringings whenever possible, and damp the surfaces of the house often. The evaporating troughs on the pipes should be kept filled, and a damping down last thing at night will be beneficial. Stop the plants when the shoots reach the trellis. Keep the soil free from weeds, and in a clean condition generally; when the roots appear through the ground give a sprinkling of artificial manure, and repeat this dressing on frequent occasions. Whilst the plants are small, remove the fruits as soon as they attain a useful size.

VINERIES.—Vines that were started early in pots will need plenty of water and feeding with liquid manure. Thinning should be carried out after the berries are well set, first removing small and worthless berries and those in the middle of the bunches. Fresh air should be given on all favourable occasions, but prevent cold draughts, and continue to close the vinery early in the afternoon. Permanent Vines that are approaching the flowering stage should have the growths stopped as soon as they have reached their limits; the amount of water should be reduced, but do not allow the house to become excessively dry. Padlicate the bunches with a rabbit's tail, or by drawing them through the hand. When the setting of the fruits is completed give the border a good watering, remove badly set bunches, and, when convenient, commence to thin the berries. Vines that are breaking into growth should be syringed to encourage them to break freely. In lofty houses it is a good plan to allow the tops of the rods to hang down from the roof. In houses where the Vines are ready for forcing the borders should be examined, and, if necessary, well watered.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOFOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

CHRYSANTHEMUM.—If cuttings of the large-flowered varieties of Chrysanthemum were not inserted last month, no further time should be lost before securing all the stock that is needed, allowing a considerable margin for accidents. It is better to put a single cutting into a thumb pot, than to put several cuttings into a larger size. Examine any cuttings that may have been inserted earlier, and if they have made roots, take care to admit sufficient air, and keep them near to the glass, and as cool as possible whilst excluding frost. I have had the cuttings covered up entirely for several days together in severe weather, and they have suffered no harm, but care was taken not to expose them too suddenly when the thaw came. Cuttings of the early-flowering, bush varieties, and single-flowered varieties may also be propagated now with the best results. At this season the Chrysanthemum cuttings here are placed on an ash-bed on a shelf in the Peach house, which has been closed recently for forcing. The cuttings of all but the large-flowered sorts are put three or more together in small pots, and the pots are placed under some square hand lights with movable tops. All the early-flowered varieties are rooted in this way. Now that seeds of single-flowering Chrysanthemums are obtainable each season, it is desirable for gardeners to sow some seed during February in a gentle warmth. At Gunnersbury we have raised several good varieties from seed, and we are propagating them by cuttings for another season. Some of these seedlings have a most desirable quality in that they form unusually dwarf plants.

HIPPEASTRUM (AMARYLLIS).—It is advisable to repot Hippeastrum bulbs each spring, and the work should be taken in hand without delay. This system will give good single bulbs, which are much better than larger ones having several offsets on each. At one time the Hippeastrum was not generally forced into bloom, but many now have them in flower well before Christmas. The bulbs that are intended for flowering in March, April, and May should be examined with a view to repotting any that need it. It will be found that most of them require potting; the old soil should be carefully shaken away, and dead and unhealthy roots removed. If the bulbs have become too large for their pots, larger receptacles must be afforded them. At the same time guard against over potting. Many bulbs will flower quite well in 6-inch pots, and the majority will not require pots larger than 8 inches in diameter. Pot firmly and carefully, employing a light fibrous loam to which a little old mortar rubble has been added. If the loam is of a heavy nature, mix some leaf-mould with it. After the potting is finished, make a selection of the bulbs with a view to introducing some at once into a temperate house, keeping others for successional flowering. Those that are started now should be plunged in leaves or other suitable material. Batches may be inserted at intervals of a fortnight or so, selecting each time the finest bulbs for the purpose. Should all the plants be required to flower at about the same time, arrangements must be made accordingly. In starting the bulbs a slight bottom heat is an advantage, but it is not essential. Any bulbs that have finished flowering must be treated carefully, and on no account must the leaves be damaged. Seedlings of last year and those in their second year may be repotted. The two-year-old plants which have not flowered this season will make fine specimens next year.

LILIUM.—The present is a good time to replenish the stock of Lily bulbs. Select those that are solid and heavy rather than the biggest specimens. Lily bulbs should not be exposed for a long time to the air, as this causes them to lose weight and the outer scale leaves to shrivel. Use pots of a moderate size only, and a soil consisting of light fibrous loam and peat in about equal proportions. Keep the bulbs well down in the pots and place a moderate layer of soil over them, leaving room in the pot for adding fresh soil when the growth is well advanced, but before the roots have begun to develop from the stem. The stem roots being of great value to the bulb should be looked after with care. After the bulbs are repotted, place them in a frame or cool pit secure from frost, and plunge them beneath a bed of cinders so that the pot is just out of sight. In

this position they may be allowed to remain until growth is well advanced in May. The old bulbs should be examined, and any that need it, repotted. If, on turning the plants out of their pots, they are seen to be rooting freely, they may be allowed to remain undisturbed, with the exception of removing a little of the old soil at the top, and replacing it by fresh loam. In the case of those needing repotting be careful not to employ pots of too large a size. A few of the largest offsets would repay for the trouble of growing them on. But nowadays bulbs can be purchased cheaply. The following Liliiums are suitable for pot culture: *L. auratum* and its varieties, including *L. a. platyphyllum* and *L. a. rubro-vittatum*; *L. speciosum* and its varieties (amongst the best of the race for autumn flowering); *L. speciosum Kratzeri* and *L. s. album novum* are both fine white Lilies; whilst of the coloured varieties of *L. speciosum*, *L. s. Melpomene*, and *L. s. roseum superbum* are of dwarf growth. *Lilium tigrinum Fortunei* and *L. t. splendens* are both excellent in pots for late September flowering. *Lilium longiflorum* (syn. *Harrissii*) is one of the most valuable of the race for growing in pots. The best forms are *giganteum* and *Takesima grandiflora*, the last named being the more vigorous as well as later in blooming. If bulbs are potted up now, these varieties may be depended upon to flower next July. *Lilium sulphureum* (syn. *Wallichianum*) and *L. nepalense* are both worth growing. A few bulbs may fail to flower, but most of them may be relied upon to furnish bloom. For these species I advise a soil containing an extra quantity of peat, but in all other respects they may be treated as advised for the other species. Both *L. sulphureum* and *L. nepalense* will do well in a cool conservatory or corridor, and they may be planted out in such structures. *Lilium Henryi* is another excellent species for conservatory decoration, but as it grows tall it is not so suitable as others for pot culture.

THE FLOWER GARDEN.

By R. P. BROTHESBON, Gardener to the Earl of HADDINGTON, K.T., Tyninghame, East Lothian.

BEDDING PELARGONIUMS.—Cuttings that were rooted in boxes may be potted, but if a heated structure is not available it will be just as well to wait a few weeks longer before doing this. Those of the Ivy-leaf section do best in 5-inch pots, but the stronger-growing Zonal-leaved sorts should be afforded pots a size or two larger. Instead of using crocks for drainage material, employ rough leaf-mould which has the advantages of providing additional root run, and there will be no crocks to remove at planting time.

BOX EDGING.—The annual trimming of Box edgings may be proceeded with at any convenient time. It can be done when ordinary operations on the land are rendered impossible by unfavourable weather. Where Box is used to form the design of flower-beds, the roots should be restricted occasionally by plunging a sharp spade deep into the ground in a line with the inner edge of the plants. Ivy also may be trimmed when the weather is unsuitable for ground operations. The finer leaved varieties, such as *digitata* do not require much trimming, but the Irish Ivy, and the variety *Emerald Gem*, will need considerable clipping; *Reginiana* needs little pruning beyond removing some of the largest leaves and shoots that have extended beyond the usual line of growth.

SHRUBS.—Any planting of shrubs that has still to be done should be proceeded with, but in cases where further planting can be left over until the autumn this alternative should be adopted, for, notwithstanding every care in lifting, transporting and replanting, spring planting involves much labour in watering during the summer. In the case of long-established shrubs to be removed next autumn, they may be prepared for the transplantation by pruning their roots at the present time. Plants of small proportions need only to have their roots cut round with a spade from 10 inches to 12 inches from the stem, but larger shrubs that need to have a mass of soil retained with the roots must be prepared with greater care. A trench should be thrown out, and the roots cut at the same time. A four-sided mass is much easier to handle than a round one, and, if it is so large as to need "boxing," the boards can be used only with effect on a square-shaped mass. The dimensions

of the root mass must be decided before proceeding to cut the roots. A fairly large shrub need not weigh more than a ton, and this weight allows for the sides to be each 4 feet long and 21 inches deep. The soil returned to the trenches should be well trampled. Roses left over from November should be planted at the earliest moment, and I prefer to shorten the shoots at once. Rose cuttings, which have been loosened during periods of frost, should be made firm in the soil, and the surface of the soil should be hoed. Shrubs which are cut down each year for the sake of their annual shoots, such, for instance, as the Dogwood (*Cornus*) and *Prunus Pissardii*, *Nedha opulifolia* and Willows may be pruned at once. Dwarf Willows should be pruned just below the surface of the ground.

RANUNCULUS. This is the proper time to plant collections of Ranunculuses. Those of the French section are very showy, and they are useful for furnishing vases. The plants should not be cultivated at less than 8 inches apart, and spaces of 10 inches may be allowed between the rows. The crowns of the claw like tubers should not be placed more than 2 inches below the ground surface. The claws from which the shoots proceed are uncommonly brittle, and much care in planting is called for.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARRIN, Aston Chilton Gardens, Buckinghamshire.

MEDLARS.—Young trees may now be planted, selecting a rich soil and a cool, moist but well-drained situation. The soil should be thoroughly prepared, and ample space given to each tree. If all goes well the trees will soon get into a fruiting condition, and they will afterwards need but little attention beyond an annual thinning out of the branches. For planting on the lawn or in grass orchards, standard or half-standard trees are best. They flower very late, escaping frosts in most seasons, and, therefore, seldom fail to bear good crops of fruit. The variety "Royal" is to be preferred to the "Dutch" or "Nottingham," notwithstanding that "Nottingham" possesses excellent flavour.

QUINCE. Like the Medlar, the Quince thrives best in a cool, moist situation. Young trees usually make rapid growth, but when the full-bearing condition is reached growth is relatively slow. Select a somewhat sheltered position for the Quince, because it flowers very late, and the fruit is still hanging upon the trees when autumn winds and rains are frequent. After the trees are fully grown, the annual pruning consists of merely cutting back the strongest shoots, and removing any weak growths that are likely to overcrowd the tree. A variety of the Quince known as "Pear" is hardy, prolific, and of good flavour.

MULBERRIES.—The Mulberry enjoys a warm, sheltered situation, and a deep, rich soil. The trees are amongst the latest of fruits to burst into bud, and therefore planting may be performed as late as April or even May. The roots are somewhat fleshy and easily bruised, unless great care is exercised in the lifting and planting operations. When the trees are in bearing they need a plentiful supply of moisture at the roots. During spells of dry weather water must be given in such quantities so as to penetrate the soil to a considerable depth. Standard trees are the most suitable kind for planting, and as single decorative specimens on the lawn or other suitable position they have considerable merit. Beyond seeing that the main growths are evenly distributed through the tree, the Mulberry requires little training or pruning. When the trees become aged, it is often necessary to support some of the main branches. Propagation can be effected by layers, though cuttings root freely, indeed, all that is necessary is to insert a good sized branch into the ground during autumn. Instances are known of branches falling naturally and taking root in the ground. The large black variety is the most suitable for growing out-of-doors.

PREPARATION FOR GRAFTING. It is too early to commence the actual grafting of Apples and Pears, but the necessary materials should be got in readiness. Old trees that have been renovated may be "headed" in preparation, and the trunk and remaining branches thoroughly cleaned. The scions now inserted in the ground should be examined to see that mice or other vermin are not injuring them.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens or of remarkable plants, flowers, trees, &c., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 13—
United Hort. Benefit and Prov. Soc. Com. meet.

TUESDAY, FEBRUARY 14—
Roy. Hort. Soc. Coms. meet at 12 noon. Ann. Meet. of Fellows at 3 p.m. Hort. Club Ann. Meet. Proposed National Daffodil Society; meeting at 4 p.m. at R.H.S. Hall.

WEDNESDAY, FEBRUARY 15—
Roy. Meteorological Soc. meet.

THURSDAY, FEBRUARY 16—
Linnean Soc. meet.

SATURDAY, FEBRUARY 18—
British Gardeners' Assoc. meet at Birmingham.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—39.3°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 8 (6 P.M.): Max. 38°; Min. 37°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, February 9 (10 A.M.): Bar. 30.1; Temp. 41°; Weather—Dull.

PROVINCES.—Wednesday, February 8: Max. 43 Land's End; Min. 35 Sea-borough.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Hardy Bulbs, Perennials, &c., at 12; Roses, Fruit Trees, &c., at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Herbaceous and Border Plants, Hardy Bulbs, &c., at 12; 6,000 Roses, at 1.30. Japanese Liliums, &c., at 2.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY AND THURSDAY—
Clearance Sale of Nursery Stock at Tumlidge Well Nurseries, 16 T. Cripps & Son, Ltd., by Protheroe & Morris, at 11.30.

FRIDAY—
Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

**British
Botanists:
Stephen
Hales.**

The Board of Botanical Studies of the University of London, has conceived the excellent idea of arranging a series of lectures on the lives and work of British botanists. The lectures, the first of which was delivered by Dr. Francis Darwin, on January 20, at the University College, are, we believe, to be published in book-form, and will thus be available to all who care to learn how great is the debt that botany owes to British investigators.

Of those botanists none occupies a higher place than Stephen Hales whose career and achievements were described by Dr. Darwin. Of Hales it may be said with truth, that he was the founder of vegetable physiology. It is true that others before Hales had dabbled with the subject, and offered conjectures and speculations on the mode of life of plants; but Hales applied to physiology the experimental method, which not so many years before his day had been demonstrated by Harvey, of immortal memory, to be the one and only way of advancing natural knowledge.

The time was propitious for the application of the experimental method. The men of science of the latter part of the 17th century had broken away from tradition and authority; they had discovered that they must look

to Nature and not to the Greeks for inspiration. As a consequence, Hales found himself in a stimulating environment. Dr. Darwin points out, for example, that as a young man at Cambridge, Hales must have seen and been influenced by Sir Isaac Newton, and that he was the contemporary of Robert Boyle and Mayo, who contributed in large measure to the founding of the science of chemistry. It is also noteworthy that, like Boyle and Mayo, Hales was himself a chemist, and brought his knowledge of that science to bear on vegetable physiology.

Again, Hales was happy in the fact that,

less an active parish priest, concerned with the welfare of his parish, and particularly solicitous in securing for it a proper water supply. He both preached and wrote against alcoholism, made experiments on ventilation, effected improvements in the ventilation of prisons, and—particularly interesting as showing the perennial nature of the problem—interested himself in the amelioration of the ventilation of the House of Commons. Greenhouses, he urged, should be ventilated by warm air, so that the plants might be rid of the "rancid air."

Altogether the picture of Stephen Hales

STEPHEN HALES (1677—1761).

like so many of our greatest scientific investigators, he was not what may be called a professional man of science. Like Cavendish, Charles Darwin, Galton and many other ornaments of British science, Hales was an amateur, in the sense that he carried on his investigations, not as a profession, but solely for the love of science. Born in 1677, Hales lived to the ripe age of 81, and passed more than 50 years of his life as Curate of Teddington. In spite of the fact that he found time to carry on the many experiments described in his *Vegetable Statics*, Hales was neverthe-

presented to us by Dr. Darwin, is that of a great man of broad views and sympathies, with a remarkable bent for practical affairs. Would that the type were commoner!

When we consider the state of science in the 17th century, and remember that the chemical nature of the atmosphere was unknown, that the existence and properties of oxygen had yet to be discovered, Hales's contributions to vegetable physiology impress us as being truly remarkable. Thus he was the first to arrive at the conclusion, published in his *Vegetable Statics* in 1727, that plants get food, not only

Photograph by F. H. Stone

NELUMBIUMS AND PONTEDERIA IN THE BOTANIC GARDENS, DAIPUR, INDIA.

from earth, but also a "sublimed and exalted food from the air."

He demonstrated experimentally that plants transpire—or "perspire" as he has it—and he measured the amount of loss of water from Sunflower and other plants by the method of weighing, which is still the best for the purpose. Further, he ascertained experimentally, that the water is given off by the leaves, and determined the rate of loss per unit of leaf-area. He ascertained that, in the Sunflower, "perspiration" goes on seven times faster in the day than on a dry, warm night; though, since stomata were unknown in his time, he failed to account for the fact. Finally, in this connection, he discovered the existence of root-pressure, measured its amount, and demonstrated that water, in passing from root to leaves, travels in the woody part of the stem.

This, though by no means the full tale of Hales's achievements in vegetable physiology, suffices to show the extraordinary insight which he gained by his own devices and experiments, without help from predecessors, into the mode of life of plants.

SUPPLEMENTARY ILLUSTRATION.—Our Supplementary Illustration represents *Nelumbium speciosum* and *Pontaderia hastata* growing in the Botanical Gardens, Coimbatore, India. The superintendent, Mr. E. H. STERRY, who obligingly furnished us with the photograph, informs us that the pond in which these plants are flourishing is 6 feet deep in the centre, and is situated in the Rose garden. The *Nelumbiums* in bloom are rose and white-flowered varieties, and both sorts produce a profusion of flowers in their season. The banks of the pond, planted with *Panicum fragrans*, *Papyrus antiquorum*, Bamboos, and other subjects, enhance the beauty of the fine aquatics. Though specimens of *Nelumbium speciosum* are sometimes cultivated in tropical houses in gardens in this country, they never grow and flower in such luxuriance here as they do out-of-doors in this Indian garden.

ROYAL HORTICULTURAL SOCIETY.—The annual general meeting of the Fellows of this Society will take place at the Horticultural Hall, Vincent Square, Westminster, on Tuesday, the 14th inst., at 5 p.m. The Committees will meet as usual. It is expected that there will be a very large show on this occasion.

THE R.H.S. SCHOOL OF HORTICULTURE.—During the past year, 38 young men between the ages of 17 and 22 have been in attendance at the School of Horticulture of the Royal Horticultural Society at Wisley, and 11 of these students gained the Society's diploma. With one exception, all have gone into some business or work connected with horticulture or forestry. Some have entered private gardens, others nurseries, others are taking up fruit-growing on their own account, either at home or in the Colonies, and so on. The course, which extends over two years, includes a thorough training in the elementary principles of scientific horticulture, and in the application of these principles to all branches of gardening work. About 11 hours a week are spent in studying scientific subjects and 29.0 practical garden work, every student being required to take his share of the ordinary work of the garden.

R.H.S. OLYMPIA SHOW.—The Council of the Royal Horticultural Society has decided to offer for open competition at the Olympia Exhibition to be held in July a 50-guinea silver-gilt challenge cup, to be called "The Coronation Challenge Cup." It will be awarded

to the exhibit which, in the opinion of the Council, is the most meritorious in the show. The Council has accepted Mr. N. N. SHERWOOD's offer of a 20-guinea silver cup. It will be awarded for fruit shown in open competition. A silver-gilt cup, valued at 20 guineas, has also been offered to the Council by the New Olympia Company, Limited, and will be awarded for Roses shown in open competition.

HORTICULTURAL CLUB.—The annual Dinner will be held on Tuesday next, February 14, at 6 p.m., at the Hotel Windsor. Ladies are specially invited. The annual meeting will take place at 5 p.m., and it is hoped that all interested in the club will be present.

ROYAL SCOTTISH ARBORICULTURAL SOCIETY.—MR. A. T. GILLANDERS, forester to the Duke of Northumberland, at Alwick, has been elected

KENNEDY BECKHANA, tab. 8558.—This species is described as the largest-flowered of the *Kennedya* in cultivation, being most nearly allied to *K. macrophylla*. The plant is a climber and produces two flowers along the shoots at each node; the blossoms are red, except for a greenish yellow patch at the base of the standard. A specimen flowered in the greenhouse at Kew, the growths being trained along the rafters.

URECOCHARIS EDENTATA.—An interesting hybrid, raised by Messrs. CLIBRAN & SON, from *Urecedina pendula* and *Eucharis grandiflora*, was described and figured by the late Dr. MASTERS in *Gard. Chron.*, 1892, vol. xii., page 214, under the name *Urecocharis Clibranii*. It is interesting that a plant almost identical with Messrs. CLIBRAN's generic hybrid was found wild by Mr. FORGET whilst plant collecting for Messrs. SANDER & SONS in Peru, the only difference

FIG. 49.—MASDEVALLIA PACHYURA: FLOWERS GREEN, WITH RED MARKINGS.

an honorary member of the Society in recognition of his services to forestry, and particularly for his work on forest entomology.

THE BOTANICAL MAGAZINE.—The issue for February contains descriptions and illustrations of the following plants:—

MELIOSMA CUNEIFOLIA, tab. 8557.—This ornamental shrub is one of Messrs. JAMES VEITCH & SONS' numerous introductions from China through their collector WILSON. The species was originally discovered by the ABBE DAVID in 1869 in the mountains of Moupin. *Meliosma* is the only genus of the *Sabiaceae* which can be grown in the open in these islands, and prior to the new introduction, *M. myriantha* was the only species that had flowered in England. Plants raised in the Coombe Wood Nursery of Messrs. JAS. VEITCH & SONS have grown about 4 or 5 feet high, and flower annually in July. In a wild state, *M. cuneifolia* attains the dimensions of a tree.

being that Messrs. CLIBRAN's plant has two teeth, each about one-third the length of the filaments, between each pair of stamens, whereas they are absent in Messrs. SANDER & SONS' specimen.

PRUNUS MICROCARPA, tab. 8560.—*Prunus microcarpa* appears to be a very variable plant, so much so that some of the forms have been described as distinct species. The plant under notice has been grown at Kew since 1900. It has glabrous leaves and finely pubescent young twigs, but another form is pubescent all over, whilst still another has small leaves and flowers, the form figured in the *Bot. Mag.* being intermediate between the two. The plant is also found to differ in the length of the fruit stalks and colour of the fruit. *Prunus microcarpa* appears to be perfectly hardy at Kew, and flowers annually in May. It does best when afforded a situation facing south.

MASDEVALLIA PACHYURA, tab. 8561.—This species (see fig. 49) was first described by REICHE in *Gard. Chron.*, September 12, 1874, p. 322.

INTERNATIONAL EXHIBITION, 1912, AND THE ROYAL HORTICULTURAL SOCIETY.—We extract the following particulars from the report and list of Fellows just issued by the R.H.S.: Subscribers and guarantors to the International Exhibition, 1912, who happen to be Fellows of the Royal Horticultural Society, are requested to understand clearly that the privileges they become entitled to in return for their contribution to the International, have nothing whatever to do with the R.H.S. With reference to such privileges they must correspond only with the International. On the other hand, the distribution of the privileges to which Fellows of the Society are entitled as a result of the arrangement made by the Council of the R.H.S. with the Executive of the International will be effected by the officers of the R.H.S., the officers of the International having nothing whatever to do with the carrying out of the arrangement. Consequently, (1) for all matters relating to or connected with subscription or guarantee to the International Exhibition, address ED. WHITE, Esq., Hon. Sec., International Exhibition, 7, Victoria Street, Westminster; and, (2) for all matters relating to privileges pertaining to anyone as a Fellow of the Royal Horticultural Society, address Secretary, R.H.S., Vincent Square, S.W. It will further be seen from this, that, (3) if a Fellow of the R.H.S. subscribes, say, £10 10s. to the International, obtaining thereby the privilege of tickets for the International to the value of £12 12s., the number of tickets to be issued by the International in respect of that £12 12s. cannot be computed on the basis of the arrangement made with the R.H.S., but must be calculated simply on their face value, and will be sent direct from the International Offices, 7, Victoria Street, Westminster. ED. WHITE, Hon. Sec. International, 1912, W. WILKS, Secretary, R.H.S.

NATIONAL SWEET PEA SOCIETY.—We are informed that the Sweet Pea *Annual* and the schedule of prizes for 1911 will be sent to all members of the N.S.P.S. at the end of the present week. Since the annual general meeting, 63 new members have joined the society, and several additional local societies have become affiliated. A number of Sweet Peas have been sent to Guildford by raisers at home and abroad; consequently the society's trials promise to be as interesting as in any previous year. Particulars of membership and affiliation may be obtained from the hon. secretary, Mr. C. H. CURTIS, Adelaide Road, Brentford.

ROYAL METEOROLOGICAL SOCIETY.—A meeting of this Society will be held at the Institution of Civil Engineers, Great George Street, Westminster, S.W., on February 15, when the following papers will be read:—"Variation of the Depth of Water in a Well at Delling, Maidstone, compared with the Rainfall, 1885-1909," by Messrs. RICHARD COOKE and SPENCER C. RUSSELL; "The Actinograph; an Instrument for Recording Changes in Radiation," by Mr. ARTHUR W. CLAYDEN, M.A.; and "New Cloudiness Charts for the United States," by Mr. KENNETH M. CLARK.

NURSERY EMPLOYEES ENTERTAINMENT.—The employees of Messrs. DICKSONS & Co., Royal Nurseries, Craigmillar, Edinburgh, held a social gathering on Friday, February 3. The company, which included Mr. JAMES WELSH, one of the partners of the firm, numbered between 40 and 50. Mr. WILLIAM McARA, the oldest employee of the firm, occupied the chair.

JUBILEE SHOW OF THE BOSKOOP POMOLOGICAL SOCIETY.—In order to celebrate the Jubilee of the Boskoop Pomological Society, a show will be held at Boskoop from April 6 to 30.

MIDLAND CARNATION SOCIETY.—The annual exhibition will be held on August 2, 3, in the Botanical Gardens, Edgbaston, Birmingham. The schedule includes 27 classes for Carnations, and special prizes are offered by Mr. ROBERT SYDENHAM in two classes for Sweet Peas. The Birmingham Botanical and Horticultural Society offers silver medals to the exhibitors obtaining the greatest number of points in the first and second divisions. The Midland Carnation and Picotee Society offer a silver medal to the exhibitor obtaining the greatest number of points in the third division, also a large bronze medal to the second highest. The Hon. Secretary is Mr. T. HUMPHREYS, Botanical Gardens, Edgbaston, Birmingham.

A NATIONAL DAFFODIL SOCIETY.—We are informed by Mr. W. B. CRANFIELD that a meeting of Daffodil growers will be held in No. 3 committee room at the Horticultural Hall immediately after the annual general meeting of the R.H.S. on Tuesday next, to consider the desirability of forming a National Daffodil Society.

ROYAL WARRANTS TO NURSERY AND SEED FIRMS.—We have received information that the Royal Warrant of Appointment to the King has been conferred on Messrs. SUTTON & SONS, Reading; WILLIAM BULL & SONS, Chelsea; WILLIAM WOOD & SON, LTD., Wood Green; EDWARD WEBB & SONS, Wordley, Stourbridge; LITTLE & BALLANTYNE, Carlisle; and JAS. CARTER & Co., Holborn.

VISITORS TO KEW.—The number of visitors to the Royal Botanic Gardens during the year 1910 was 5,546,302. These figures show an increase of 186,031 over those of the previous year, and are the largest numbers on record. During the 10 years 1900-1909, 20,023,749 persons have visited the gardens, giving an average of 2,002,374. The total number of visitors on Sundays during 1910 was 1,614,085, and on week days 1,952,217.

ADDITIONS TO THE KEW COLLECTIONS.—According to the *Kew Bulletin* the largest consignment of new trees and shrubs received during 1910 was from the Arnold Arboretum. The Assistant Curator visited this establishment during the summer with the result that about 500 species and varieties were noted as desirable for the Kew collection. Almost all these were sent by Professor SARGENT, and arrived in perfect condition early in December. An experiment was made in bringing over fresh cuttings. The Assistant Curator returned on the "Campania" and, by the kindness of the Cunard officials, was allowed to place two baskets containing about 50 packets of cuttings in one of the cold storage rooms where the temperature during the voyage was kept at about 42° Fahr. Ten days elapsed between taking the cuttings from the plants in the Arnold Arboretum and placing them in the propagating frames at Kew, but although this was in mid-July, they arrived almost as fresh as when they were cut, and only six sorts failed to strike root. Among the more interesting plants sent by Professor SARGENT were a set of American Amelanchiers—a genus which badly needs revision; several new species of North American *Esculus*, a set of dwarf American *Crataegi*, about 160 Chinese trees and shrubs introduced by Mr. E. H. WILSON, a set of American and Asiatic Willows, and such rare plants as *Leitneria floridanum*, *Larix lyallii*, *Kalmia caroliniana* and *K. microphylla*, *Pinus pentaphylla*, *Pteroceltis Davidiana*, *Tripetalicia bracteata*, and *Vaccinium membranaceum*. Of special interest was a new and undescribed species of *Hamamelis* from Missouri remarkable as flowering in spring like the Asiatic species; the only American species previously known, *H. virginica*, flowers in

autumn. Mr. MAURICE L. DE VILMORIN sent in March a most interesting consignment of new species raised by himself from Chinese seeds. Most were unnamed, but amongst them were *Ailanthus sutchuenense*, and the beautiful and very distinct *Clematis chrysocoma*, which has since flowered and been figured for the *Botanical Magazine*. Messrs. VEITCH have, as usual, been generous donors of their new Chinese plants, and through them the following have been added to the Kew collection: *Meliosma cuneata*, *Picea complanata*, *Pterocarya hupehensis*, *Rosa Willmottiae*, *Rhododendron nigropunctatum*, *Viburnum thaeiferum*, *V. buddleifolium* and *V. Davidii*, *Lonicera yunnanense* and *Tsuga yunnanense*. From the Japanese authorities at the recent exhibition at Shepherd's Bush several Japanese trees, shrubs, and seeds were received, amongst which the most noteworthy were two specimens of the Japanese Douglas Fir (*Pseudotsuga japonica*); although in rather poor health they are on their own roots, and hitherto this Conifer has only been known in Britain by a few miserable grafted plants. A packet of seeds of *Picea Breweriana*, hitherto the rarest of Spruces, was sent by Miss ALICE EASTWOOD, and the seeds germinated freely. Cuttings of *Populus Thevestina* were brought from Algeria by the Assistant Director, some of which have taken root. This Poplar is very distinct in its white bark and fastigate habit.

APPOINTMENTS ABROAD.—According to the *Kew Bulletin* Mr. F. C. McCLELLAN has been appointed Director of Agriculture, Zanzibar, in succession to Mr. R. N. LYNE, who has been appointed Director of Agriculture, Mozambique. Mr. M. T. DAWE lately Officer-in-Charge and Superintendent of Forests in the Botanical, Forestry and Scientific Department, Uganda, has been appointed Director of Agriculture under the Mozambique Company. Mr. HARRY THOMAS, a member of the gardening staff at Kew, has been appointed by the Secretary of State for India in Council, on the recommendation of Kew, a probationer gardener for service in India.

DILIGENT INTEREST IN PLANTS.—The Council of the Royal Horticultural Society have introduced a card of "Recognition of Diligent Interest in Plants." Issued in response to frequent applications by school authorities for some token of encouragement of work with plants amongst scholars, it is to be awarded to the boy or girl (or both) who, in the yearly school competitions in plant cultivation, or garden plot-keeping, or nature study, has secured the 1st prize. The cards are 12 inches by 8 inches, and may be had on application to the Secretary, R.H.S., Vincent Square, London, S.W. (price 6d. each), signed by the head master or mistress, and a member of the educational authority concerned. The application should contain information as to (a) the nature of the competition, (b) the number of competitors, (c) the judges, (d) the number of prizes awarded in the competition, (e) the full name of the 1st prize-winner. The Council of the R.H.S. will at their own absolute discretion grant or withhold this "recognition."

EUROPEAN ALPINE PLANTS.—Messrs. ROUTLEDGE expect to issue a volume on the Alpine plants of Europe by H. STUART THOMPSON during next month. The work will comprise botanical descriptions of 700 of the more important Alpine plants which inhabit the Swiss Alpines and other mountain ranges. Short cultural hints will be provided on plants suitable for British rock gardens, and the work will contain coloured plates representing 300 species. Our readers who are familiar with Mr. THOMPSON'S notes upon Alpine subjects will look forward with interest to the publication of his further contribution to our knowledge of Alpine plants.

FOG AND FROST IN THE GLASGOW DISTRICT.

—Glasgow has been visited recently by a dense fog, which lasted for four days and was accompanied by frost. In order to show the effect on vegetation in the public parks of the city, Mr. WHITTON, the Superintendent of the Parks and Botanic Gardens, has sent us specimens of shrubs and trees coated with sooty matter as had as may be found in a London park in November. Mr. WHITTON states that the fog was the worst experienced in Glasgow since November of 1909.

THE EFFECT OF BASIC SLAG ON PASTURES.

—So long ago as 1896 Professor SOMERVILLE introduced the ingenious method now known as "manuring for mutton;" the value of a manure being estimated in terms of weight of sheep pastured on the manured plot in comparison with the weight of an equal number of similar animals pastured on unmanured land. The experiments, of which a full summary is published in the *Journal of the Board of Agriculture* (vol. xvii., No. 10, Supplement No. 5), demonstrated in a striking manner the high efficiency of basic slag in improving the feeding value of pasture. A single dressing at the rate of half a ton per acre not only brought about an immediate increase in "mutton," but continued to produce this result for no fewer than nine years. It is curious, moreover, that in these experiments the basic slag produced a better effect when put on in mid June than when applied at the more usual time, namely winter. Basic slag proved superior to superphosphates. Potash, in addition to a phosphatic dressing, further increased the yield, but the cost of the manure was not made good by the increase. Lastly, the subsequent addition of nitrogenous manure in the form of sulphate of ammonia or nitrate of soda, though it increased the herbage, reduced, as a rule, the yield of mutton; whence Professor SOMERVILLE concludes that the use of such nitrogenous manures on pasture would appear to be bad practice.

BLACK CURRANT "BOSKOOP GIANT."

—In the experience of most cultivators, the vigorously-growing variety of Black Currant known as Boskoop Giant, has proved itself in a special degree capable of resisting attacks from the Bud Mite (*Eriophyes ribis*). That there is a limit to its resistant powers, however, is proved by some photographs which have been sent us by an old and trusted correspondent in Worcestershire. The bushes illustrated have every shoot attacked with the pest. Indeed, they present as bad an appearance as we have ever seen in any variety of Black Currant. There is no reason to suppose that the general experience of cultivators is at fault, or to doubt that the Boskoop Giant is still the best variety for planting in most districts. We only refer to the matter to show that there are exceptions to the rule, for our correspondent states that six years ago he saw the variety bearing evidence of the disease in another garden in Huntingdonshire.

TREATMENT OF POTATOS FOR SCAB.

—The usual methods of treatment of seed Potatos for scab consists in steeping them either in formaldehyde (formaline), one pint of commercial formaline to 30 gallons of water, for 2 hours, or in a solution of corrosive sublimate made by dissolving 2 ounces in 16 gallons of water for 1 to 1½ hours. When larger quantities have to be treated it is recommended by Mr. L. C. CORBETT (U.S. Department of Agric. Farmers' Bulletin 407) to subject them to formaldehyde gas, produced by acting on commercial formaline with potassium permanganate. Where an airtight shed is available, this treatment is found to be both effective and economical. The sacks are placed fairly close together, but not so close as to prevent air circulating freely between them; nor should they stand directly on the ground or floor, since it is advisable that it should be moistened before the fumigation. A space of about 6 feet is left in

the centre of the shed, and in this space a galvanised tub or pan is placed. Permanganate of potash is spread in a thin layer in the pan, formaline is added, the mixture is stirred, and the shed vacated and closed. After 24 hours the door may be opened and the room ventilated. For every 1,000 cubic feet of space 25 ounces of potassium permanganate and three pints of formaldehyde are required.

"THE ORCHID REVIEW."—In the issue for February we note with interest a first instalment of the continuation of the *Orchid Stud-Book*, in which the genus *Odontioda* is fully dealt with. Primary and secondary hybrids are now separated, the former containing 15 additions and the latter 14, which shows how rapidly the genus is growing. A new hybrid genus is also described, in which the rules of the committee appointed by the R.H.S. to consider the nomenclature of multi-generic hybrids are applied for the first time, a hybrid between *Miltonia vexillaria* and *Odontioda Vuylsteke* being named *Vuylstekeara*, in honour of its raiser. An article is devoted to the habitat of *Cymbidium Tracyanum*, on which definite information is at last forthcoming, and another to the much-debated *Laelia Crawshayanum*, which has now been raised artificially from *L. anceps* and *L. albida*. The illustrations include a portrait of Sir Trevor LAWRENCE, Bart., and a half-tone picture of the new hybrid *Paphiopedilum Sladdenii*. The work is now printed on art paper, with a much improved effect in the illustrations. We note that the sign of hybridity is no longer used, and the *Orchid Review* is thus brought into line with our own practice. The sign was adopted many years ago to distinguish hybrids from species, but in the case of Orchids it may be said to have broken down under its own weight.

APIOS TUBEROSA.—In respect to Mr. LYNCH's note and illustration of *Apios tuberosa* (January 7, p. 4), Mr. J. J. POTTER, writing from Exhibition Park, Toronto, Ontario, states that the species, which is native there, is one of the most accommodating of climbing plants. He has seen it growing on the cliffs at Niagara Falls, where it was constantly saturated with the spray, and also growing on exposed dry banks and yet flowering well. At the same time, the plant may be said to prefer moisture. It is rather a shy seeder, and the best way to propagate it is from tubers, which are easily procured. Our correspondent is surprised that such a useful plant should not be found oftener in cultivation.

THE POLYTECHNIC.—The Regent Street Polytechnic, founded by QUINTIN HOOG in 1882, is being rebuilt at a cost of £90,000. The rebuilding fund was inaugurated by a grant of £20,000 from the London County Council and a loan of £20,000 from the City Parochial Foundation. In addition to the £40,000 thus contributed, a further sum of £47,500 has been subscribed and promised by Lord LEITH of Fyvie, the governors, members and students of the Polytechnic, and other friends intimately associated with the institution. The rebuilding fund will be kept open till Easter next, and a sum of £2,500 has been reserved for members past and present, so that as many as possible may, in varying amounts from £100 to £1 be participators in the scheme. Subscriptions may be paid in instalments, terminating in June 1912, and should be sent to the Secretary, 309, Regent Street.

PUBLICATIONS RECEIVED.—*Agricultural and Horticultural Association, Ltd.* Forty-third Annual Report of the Association's Operations with Report of the Annual General Meeting of Members, 1910. (London: Agricultural and Horticultural Association, Ltd., Long Acre.)—*The Feeding of Crops and Stock*, by A. D. HALL, M.A., F.R.S. (London: John Murray) Price 5s. net.—*The Liverworts (British and Foreign)*, by Sir Edward FRY, G.C.B., and Agnes FRY. (London: Witherby & Co.) Price 1s. 6d. net.—*Simple Lessons in Nature Study*, by John O'NEIL. (London: Blackie & Son, Ltd.) Price 1s. net.

SCOTLAND.**THE PHARMACY ACT IN SCOTLAND.**

CONSIDERABLE trouble is being caused to nurserymen and seedsmen in Scotland by the efforts of the Pharmaceutical Society to secure convictions in case of any departure from the legal formalities in the sale of poisons by seedsmen. In several cases, members of the licensing bodies have raised the objection that sufficient conveniences for the supply of the articles required are provided by chemists, and that, therefore, licences should not be granted to seedsmen. In few cases, however, have these objections been of any avail, for in the vast majority of instances applications for licences have been granted.

The efforts to obtain convictions have been attended with better success, and several seedsmen have been convicted for selling the articles in a manner not allowed by the Act. In one case, selling from unlicensed premises was the cause, it being alleged that the articles were removed from the licensed store and sold at a counter at which articles of food were retailed. This point has in many cases been used to enforce the construction of separate counters from those on which articles of food, such as fruit, are sold. Quite a number of convictions have been obtained on the ground that the actual licensee did not effect the sale, and that unauthorised persons were the actual sellers. The frequency of these convictions has led to greater precautions on the part of the seedsmen, and in most establishments strict orders have been given to salesmen not to supply the articles asked for in the absence of the actual licensee. Greater elasticity is required in the working of the Act, and some arrangement should be effected by which more than one member of a firm, or manager of a firm, should be licensed. The question of the fee payable for the licence is also worthy of consideration, this varying according to the discretion of the licensing body. Five shillings per annum is, we believe, not an uncommon fee for each person included in the licence.

AN ANCIENT SCOTTISH GARDEN.

THE old garden at Kenmore Castle has for some years suffered comparative neglect, although the bowling green, on which Viscount Kenmore is said to have been playing when he was summoned to join the Stuart army in 1715—an ill-fated enterprise, which ended in his execution—and the famous Beech hedge have been kept in good order. Since the castle has been leased to Mr. and Mrs. John Gordon, members of a branch of the old family, great improvements have been in progress in the gardens, which will soon be worthy of the fine castle to which they are attached. Magnificent old wrought-iron gates have been placed at the principal entrances to the gardens, and good herbaceous borders planted, together with many Roses and other shrubs. The sundial, one of the oldest in Scotland, and dated 1625, still stands in the garden, and all the old features of value are being carefully preserved. The Beech hedge is inferior in size to that at Meikleour, in Perthshire, but, so far as Scotland is concerned it probably ranks next to that fine specimen.

A FRAUDULENT EMIGRATION SCHEME.

THE sequel to the alleged fraud recorded in these columns on p. 74, took place in the Sheriff's Court, Glasgow, on February 2, when Alexander McKinnon McIntosh, described as a jobbing gardener, was charged with fraud and attempted fraud. The accused pleaded guilty. Fortunately, the bulk of the money had not been remitted. Sheriff Boyd, who said that the case was a serious one, sentenced the prisoner to 18 months imprisonment. It appears that the persons engaged by the so-called Scottish Gardeners' Association included 12 in Dundee, 15 in Oban, and others in Edinburgh and St. Andrews.

ODONTOGLOSSUM CRISPUM PEACOCK.

In fig. 50 is illustrated the variety of *O. crispum* which was shown by Lieut. Colonel Sir George L. Holford, K.C.V.O., Westonbut, at the meeting of the Royal Horticultural Society on the 51st ult. The flowers are pure white, with bright red-crimson blotches on each segment. The fringed lip has a chestnut-brown blotch in front of the yellow crest. The illustration of the flower spike is reproduced from a photograph, and the single flower is shown natural size from a sketch by Mr. Worthington Smith. The Orchid Committee awarded this handsome variety a First-class Certificate.

English fruits. Of all the growers sending to Covent Garden, I doubt whether there are half-a-dozen who pack fairly and trouble to select and grade in two or three sizes the produce they send. The majority fill the bottom of the bushels with small and mixed sizes of fruits, finishing off the top with a couple of layers of good, large fruits. From this cause the buyer always mistrusts the package. Now, with the imported fruits, whether in barrels or boxes, you may rely on the grading, whether of No. 1, 2, or 3, and that the size and quality at the bottom is equal to those found on the top. As regards cooking

varieties as Bramley's Seedling or Wellington would, at least this season, have found it profitable to hold for present sale, as 8s. to 10s. per bushel is now being paid for these varieties. Some good fruits of Bramley's Seedling from Ireland, packed in barrels similarly to the Canadian, are now arriving in Covent Garden, and appear to sell readily at about 22s. per cwt. These fruits are well packed and graded. The price mentioned is for best samples. With dessert Apples, home-grown fruits are nowhere seen, and the supply appears to be exhausted. Mr. Bartlett suggests that the imported Apple is more favoured because of the

FIG. 50.—ODONTOGLOSSUM CRISPUM "PEACOCK;" FLOWERS, WHITE WITH REDDISH-CRIMSON MARKINGS.

(Awarded R.H.S. First-class Certificate on January 31 last.)

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

IMPORTED V. HOME-GROWN APPLES. In the discussion regarding the sale of imported and home-grown Apples (see pp. 58 and 76), it seems that neither correspondent has exactly stated the right cause for the frequent preference of trade buyers of Canadian or Nova Scotian fruits over home-grown fruits. What I refer to is the bad packing and grading so often found in bushels or

varieties of Apples, the appearance does not so much matter, although many of the public that do not really know the quality of home-grown cooking Apples would be more likely to purchase a pretty Baldwin than a green Bramley's Seedling or other variety. There are, however, many purchasers who are willing to give an extra penny per lb. for a good English Dumelow's Seedling (Wellington) or Bramley's Seedling for its sterling quality as compared with the more showy imported fruits. I should have imagined that English growers with good crops of such long-keeping

softness of its flesh and easy mastication. This may be so in some instances, but, seeing that the sale of Newtown Pippin as a dessert variety, with its comparatively hard flesh, exceeds that of all other kinds put together, I am inclined to think that appearance is a more potent factor in the sale of these imported fruits. It would, no doubt, be interesting to many growers if Mr. Bartlett would state what varieties of Apples have been treated as recommended on p. 41, and the date of gathering. C. Herrin, Fruiterer, North Finchley.

SOCIETIES.

ROYAL HORTICULTURAL.

THE following extracts are taken from the *Report of the Council to be presented at the 107th annual general meeting of the Society to be held at the Royal Horticultural Hall on Tuesday next, February 14:*—

DEATH OF OUR PATRON

The lamented death of King Edward has been a great loss to our Society, of which he was the patron, and in which he took a warm interest. The Council have subscribed one hundred guineas, in the name of the Society, to the Lord Mayor's Fund for a National Memorial.

NEW PATRONS.

Fellows will be glad to hear that their Majesties King George V. and Queen Mary have graciously consented to become Patrons of the Society.

VICE-PRESIDENT.

His Grace the Duke of Bedford, K.G., has accepted office as a vice-president of the Society.

WISLEY GARDENS.

The Council are pleased to notice that the interest taken by the Fellows in the Society Gardens continues to steadily increase, as testified by the number visiting Wisley.

Suitable accommodation for the gardeners employed is being gradually provided, and the past year has seen the erection of a new Bothy for a foreman and five journeymen.

Several recent valuable gifts of Orchids, and the necessity of giving the students a proper training in the cultivation of this very popular class of plants, made it essential to erect an Orchid house.

A new stable has also been built. Research and experimental work is being regularly carried on, and reports on soil sterilization, and on the trial of various plants, will appear shortly in the *Journal*.

A large number of Mr. Wilson's newly introduced plants from China, generously sent by the Hon. Viscountess Gibbs and Messrs. James Veitch, have been added to those already planted.

The death of the hardy plant foreman, Mr. Frost, is recorded with sincere regret.

SHOWS.

SPRING BULB SHOW.

The Spring Bulb Show on March 5 and 6 was one of the greatest successes of the year. It will probably be an annual feature. The Show in 1910 was on March 14 and 15.

TEMPLE SHOW.

It is hardly necessary to say that the Temple Show was a great success, being favoured with glorious weather. The Society is much indebted to the treasurer and to the exhibitors for again lending their gardens.

HOLLAND HOUSE SHOW.

The Holland House Show proved more popular than ever, the number of visitors exceeding the highest record of any previous year.

The President and Council, speaking in the name of the Society, thank Mrs. Countess of Helstorf, most warmly, for her kind and oft-repeated hospitality in lending her park to the Society.

Fellows are particularly asked to notice and assist in making it widely known that, owing to circumstances over which the Council have no control, the Summer Show of 1911 will not be held at Holland House but at Olympia, Kensington, on July 4, 5, and 6.

AFFILIATED SOCIETIES CHALLENGE CUP.

The cup, competed for by exhibits of Apples and Pears from our Affiliated Societies, was won by the East Anglian Horticultural Society. It will be offered for competition on October 19, 1911, the winners of the last two years being excluded from again taking the Challenge Cup. Should, however, the winners of 1909 or 1910 exhibit again, and either of them be again adjudged first in order of merit, the Council will award to such Society a smaller silver cup, instead of the medal offered as a second prize.

THE VEGETABLE SHOW.

This Show having been fixed for a late date, to avoid clashing with another similar Show, was not an unqualified success. In 1911 it will be held on September 26; the schedule will be enlarged in some directions, and modified in others, to accord more nearly with the wishes of exhibitors.

AUTUMN FRUIT SHOW.

The Autumn Fruit Show attracted the usual admirable display of British-grown fruits, there being hardly any noticeable falling off, in either the number or the quality of the entries, as a result of the distinctly unfavourable fruit season of 1910. The Council regret the comparatively small number of Fellows visiting this Show. In 1911 they have fixed Tuesday and Wednesday, October 10 and 11, for the Show, instead of the Thursday and Friday on which it has been hitherto held, hoping that the habitual Tuesday attendance of Fellows will bring more visitors to the hall.

COLONIAL FRUIT SHOW.

The Colonial Fruit Show was an unprecedented success, both in the magnificence of the display and the number of visitors. The Right Hon. Sir Edward Grey, Bart., H.M. Secretary of State for Foreign Affairs, opened the exhibition. The large orchestral platform, which rises in many tiers to a height of 15 feet or more, was entirely covered, from one side of the hall to the other, with boxes of splendid Apples from British Columbia. This exhibit was of such a unique character that the Council voted it a Gold Hogg Memorial Medal, this being the only occasion on which such an

award has been made. A full report of the Show will appear in the *Journal*.

MASTER LECTURES.

The third and fourth Lectures in memory of the late Dr. Masters were delivered by Mr. A. D. Hall, F.R.S., on February 22 and March 22. His subject was "The Adaptation of the Plant to the Soil" (see R.H.S. *Journal*, vol. XXXVI, part 1).

Mr. G. F. Scott Elliott, M.A., B.Sc., F.L.S., will deliver the 10th lectures on February 28th and March 14. Subjects, "Recent work in Seed Selection," and "The Origin of Varieties."

LAWRENCE MEDAL.

The third Lawrence Gold Medal has been awarded by the Council to Messrs. James Veitch for a series of highly meritorious exhibits during the year 1910, including the wonderful collection of stove and greenhouse plants shown on October 25.

HOSPITALITY TO JAPANESE.

An opportunity of recognizing the debt which British horticulture owes to Japan, was afforded by the Japanese British Exhibition, and the Council took advantage of it in two ways. A deputation visited the gardens and horticultural exhibits at the Shepherd's Bush Exhibition, and made a considerable number of awards. They also invited the Japanese horticulturists in London, with a few other prominent Japanese gentlemen, to be guests of the Society at luncheon at the Holland House Show. These courtesies were warmly appreciated.

VISIT TO WOBURN.

One of the pleasant recollections of the year is a visit to the Experimental Fruit Farm at Woburn, by special invitation of His Grace the Duke of Bedford. The party, consisting of members of the Council and of the Scientific and Fruit Committees, were shown all the valuable and interesting research and experimental work which the Duke, with the assistance of Mr. Spencer Pickering, F.R.S., is carrying out at Woburn, and were also most handsomely entertained at the Abbey. The President and Council desire to thank the Duke and Mr. Spencer Pickering for the great interest they take in the Society and its work.

DEPUTATIONS.

Deputations from the Council attended the following shows, and made awards, viz.:—The National Flower Show at Hadden, on April 15, and the Fruit Congress at Ilsham, on October 29.

ORCHID NOMENCLATURE.

A report in nomenclature, summarising the opinions of experts and hybridists at home and abroad, was sent from the Council to the Brussels International Horticultural Congress, which met in April 1910. Dr. Kende, F.R.S., and Mr. E. A. Bowles, M.A., represented the Society at the Congress, and it is gratifying to know that the report of the Society was approved in some of its most important details. The report is now awaiting final confirmation by the next International Botanical Congress, before being finally adopted for international use.

PRITZEL'S INDEX.

The negotiations for the re-issue of *Pritzel's Iconum Botanicarum Index* by the co-operation of a number of horticultural and botanical societies, not having progressed satisfactorily, a committee was appointed by the Council to consider the matter. This committee has met many times during the past year, and the Council hope that success may even yet crown their labours.

LIBRARY.

One of the most gratifying results of the past year's work is the establishment of the Lindley Library on a sure basis, as a perpetual adjunct of the Society. Under the original terms of the trust, the trustees might at any time have removed the books from the custody of the Society. As long as that state of uncertainty existed the Council never felt justified in spending more than a small sum annually out of the funds of the Society, in developing this valuable collection of horticultural and botanical works. The trust deed has at last been modified—the existing trustees have retired, and the Royal Horticultural Society, acting by and through its Council, has now been made sole trustee, with the determining voice as to where the books shall be kept. The library having thus become permanently attached to the Society, the Council have no longer any hesitation in spending the Society's funds on the purchase of valuable books, and a Committee consisting of Messrs. H. J. Veitch (Chairman), E. A. Bowles, C. Barnard Payne, J. T. Bennett-Poe, and Dr. Daydon Jackson, with the Treasurer and Secretary ex-officio, has been appointed, to advise and assist the Council in the work of strengthening the library.

OLYMPIA SHOW, JULY 4, 5, 6, 1911.

Holland Park, as has been already mentioned, not being available this year, a new site for the Summer Show had to be found, and after considerable anxiety Olympia was fixed upon as the most advantageous place. The Great Hall and Annex of Olympia will afford ample space for a magnificent exhibition, and the Council are sparing no effort to so arrange its details that the Show may be an unqualified success in every way. The usual features of a summer show—the open air, spacious lawns, and canvas tents—will be absent, but in their place there will be the advantages of wider gangways, dryness under foot, freedom from any of the unpleasant vagaries of our English climate, and last, but by no means least, the possibility of keeping the Show open in the evening.

The Main Hall will be surrounded by tiered staging rising to a height of 15 feet, upon which imposing groups of plants and flowers can be arranged, and at a lower level the smaller exhibits on talling will be so placed as to leave a wide central avenue. The Annex is being reserved for rock and water gardens, grouped around a testoom and pillared Rose garden.

Application for the tiered staging for large groups (each allotment has a frontage of 28 feet with a depth

HAMAMELIS MOLLIS.—On p. 65 Mr. Wyndham Fitzherbert mentions only one of the Witch Hazels, namely, *Hamamelis arborea*. This is a native of Japan, and a beautiful shrub, but is surpassed by the newer Chinese species, *Hamamelis mollis*. This differs from *H. arborea* in many well-marked features, principally in its large, broadly-ovate leaves, clothed with soft, felt-like hairs, from which character the specific name is derived, and also from the flowers, which are larger than those of *H. arborea*, and instead of the petals being crimped, as in that species, they are flat, or nearly so, with hooked tips. What is more, instead of the old-gold tone of *H. arborea*, the flowers of *H. mollis* are of a rich, golden yellow, and open a fortnight or so earlier than those of the older species. *H. mollis* is of a more bushy habit. Both species are, however, so beautiful, that there are not many gardens where a space could not be found for the two. *H. japonica*, somewhat like *H. arborea*, but of dwarfer habit, and a pale-yellow form known as *Zuccariniana*, are also well worthy of recognition. Concerning *Hamamelis mollis*, it is generally regarded as having been found by Dr. Henry in 1887, and introduced into cultivation some years later by Messrs. Veitch, but *Hortus Veitchii* claims Charles Marries as its introducer. W.

WINTER-FLOWERING SHRUBS (see p. 65).—*Daphne indica rubra* is exceedingly hardy and established plants flower from Christmas to June. I suppose it does not like a deep clay soil or else resents the blossoms being cut, because after about 10 to 15 years the plants here are apt to die. Well-drained leaf-mould would probably be the best rooting medium. *Daphne indica alba* is a very tender subject and dies almost at once with us. *Lonicera fragrantissima* is an evergreen species with roundish, dark green leaves. It grows into a large bush or tree, and does especially well in the Bath Botanic Gardens. *L. Standishii*, which has long leaves that are deciduous, is not nearly so attractive as *L. fragrantissima*. The following varieties of *Erica mediterranea* are in bloom from December till late in spring:—*hibernica* (red), *hybrida* (paler red), *alba*, and *glauca*. *Hamamelis arborea* is a fine-flowering shrub. In the Bath Botanic Gardens there is a specimen nearly 12 feet high. The best type of *Hamamelis arborea* is erect in growth, and the lateral branches develop from the main stems at an acute angle. The so-called improved varieties are not nearly so good as the type. *F. Kitley, Oldfield Nursery, Bath*.

A PROPOSED GLADIOLUS SOCIETY.—There have been references in these columns on several occasions to a society formed in America for the purpose of furthering the cultivation of the Gladiolus. It has been suggested in several quarters that a Gladiolus Society should be formed in like manner in England on the lines of the Rose, Chrysanthemum, and Sweet Pea Societies. As I take a great interest in the cultivation of the Gladiolus, I am endeavouring to organise a society, and should be greatly indebted if you would kindly give the project some notice in your valuable journal. I have received a promise of support from the Royal Horticultural Society if a society is established, and I am in correspondence with several gentlemen and professional growers, with a view to forming a council to elect a president and draw up rules for such a society. I shall be pleased to hear of anyone wishing to become a member, and I will send particulars on receipt of a postcard addressed to me as below. It is proposed to fix the subscription at £1 1s. per annum. I need hardly point out how much a society could do for the improvement and extended cultivation of the Gladiolus, which at present is not nearly so well known in this country as it should be. On the formation of the society, the R.H.S. are willing to grant us permission to hold an exhibition of Gladiolus at the Horticultural Hall during the flowering season, and prizes would be offered by the new society for the various types of Gladiolus. *K. Atkinson, Managing Director, Locksheath Nurseries, Ltd., Southampton*.

of 25 feet), or for a floor space in the Annex, should be made to the Secretary of the Society on or after February 14, when a ground plan of the Great Hall will be on view.

Accommodation for sundries has also been provided round the walls of the Main Hall. Those wishing to exhibit should at once book their position by applying to the Secretary.

1911 ALPINE HORTICULTURAL EXHIBITION, MAY 22-30, 1912

Most of the Fellows will have heard that an International Flower Show is to be held in London in the spring of 1912. It should be fully understood that the Royal Horticultural Society is not organizing this exhibition, which will be worked by an absolutely distinct and entirely separate and independent organization. The Council have, however, most warmly welcomed the proposal, and will render the exhibition every assistance in their power.

The Executive of the Exhibition, recognizing the importance of securing the great weight of horticultural interest vested in the Society, have approached the Council with a view to establishing a suitable friendly working arrangement between the two bodies. Negotiations have accordingly been actively proceeding, whereby it has been decided that—

(a) The Council agree—

- To forego in 1912 the great Spring Show hitherto held, by kind permission of the treasurer, master and members, in the gardens of the Inner Temple.
- To contribute £1,000 towards the expenses of promoting the International Exhibition, and
- To guarantee a further sum of £4,000 against the hardly probable contingency of there being an ultimate loss on the Exhibition.

(b) The Executive of the International Exhibition, 1912, agree—

- To give to all Fellows of the Society certain special and definite privileges (which will be published in due time) in regard to the purchase of tickets for the Exhibition; and
- To allow all such tickets purchased by Fellows of the Society to be transferable.

Fellows are particularly requested not to write to the Society on the subject of this Exhibition, but, if any communications are necessary, to address them to Edward White, Esq., Hon. Sec., International Horticultural Exhibition, 7, Victoria Street, S.W.

RECOGNITION OF DILIGENT INTEREST IN PLANTS.

In response to frequent applications by school authorities for some token of encouragement of work with plants amongst their scholars, the Council have founded a card of "Recognition of Diligent Interest in Plants." It is to be awarded to the boy or girl who, in the yearly school competitions in plant cultivation, or garden-plot keeping, or nature study, has secured the first prize.

OBITUARY.

In addition to the loss of our late Patron, King Edward, the first name which will occur to any Fellow of the Society who knows anything whatever of the Society's history will be that of Baron Schroder. From the very difficult days of 1887, up to the last year of his life, the Society had no better friend than the Baron. In 1888 he was one of the first to help pay off the debt which then threatened the Society's very existence, and much as he disliked the Drill Hall he loyally supported the Council, and was himself an active member of it. When prosperity came he began to urge the Council to embark on a hall of their own, and had it not been for the great financial difficulties in the City of London in the years 1891-2 he would then have succeeded in his project of building a hall on the Thames Embankment not far from the Temple. Greatly disappointed, the Baron was not disheartened, and no sooner was the question mooted—"How shall we celebrate the Centenary of the Society?" than he answered unhesitatingly, "Build a hall," and himself secured the present site, and gave £5,000 to the building fund, besides providing all the new book-cases, fittings and furniture for the library.

To perpetuate the memory of the Baron, the Council have established a Schroder life-pensionership, under the rules and regulations of the Gardeners' Royal Benevolent Institution, and Mrs. Wildsmith, the widow of an eminent gardener, who did much to help the Society in the difficult years of 1887, 1888 and 1889, has been appointed the first Schroder pensioner.

Death has removed many other prominent Fellows during the year. Well known amongst them were Mr. G. S. Saunders, F.L.S., F.I.S., a valued member of the Scientific Committee and for a short time Editor of the Society's *Journal*; Lord Decies; Sir Charles Strickland, Bart.; Louisa, Lady de Rothschild; Max Leadham, C. B. Plowright, F.L.S.; J. Forster Alcock; Brewitt O. Brewitt; W. J. Nutting; H. A. Tracy, etc., etc.

VICTORIA MEDAL OF HONOUR.

Gaps in the ranks of our Victoria Medal of Honour have occurred by the deaths of Mr. W. Buxall, Mr. R. W. Ker, Mr. James M. Indo, Mr. David Thompson, and Baron Schroder. To fill these vacancies the Council have appointed Mr. Coombes, Mr. Cypher, Mr. F. R. Edder, Mr. H. B. May, and Mr. A. H. Pearson, J.P., all of whom are well known in various branches of horticultural work.

PENSION SCHEME.

A scheme of annuity pensions for members of the Society's staff has been arranged during the year. The annuity is provided for by equal contributions from the salaries of the officials concerned and the funds of the Society. Each pension matures at the age of 65 or at death if occurring before.

THE HALL.

The hall has been kept in thorough repair. A travelling platform has been added in the highest part of the roof to ensure the safety of the men working there.

It is intended to redecorate the hall in August, 1911, and it will therefore be closed from August 2 to 28. In consequence there will be no flower show on August 15.

PRESENTS.

The Council acknowledge and tender their warmest thanks for the many gifts which have reached them during the year. Valuable contributions have been given to the library; also to be mentioned are portraits of the late Lord Penzance from Miss Jekyll, and of the late Sir Charles Strickland from his daughter, Mrs. E. A. Willoughby, the late Mr. George S. Saunders's collection of insects from Mrs. Edward Saunders; Orchids from Baron Bruno Schroder and Messrs. Sander; a further large assortment of Mr. E. H. Wilson's introductions from China sent by the Hon. Vicary Gibbs and Messrs. Jas. Veitch; a collection of Rhododendrons from Mr. John Waterer; a set of all the reports and papers published since 1843, recording Rothamsted investigations, presented by the Board of Agriculture with the sanction of His Majesty's Treasury, gifts of lantern slides from Mr. Jas. Hudson, V.M.H., and Captain A. Dorrien-Smith.

ANNUAL PROGRESS.

The following table will show the Society's progress in regard to numerical strength during the past year.

LOSS BY DEATH IN 1910.		
	£	s. d.
Hon. Fellows	7	0 0 0
Life	13	0 0 0
4 Guineas	3	12 12 0

Deduct loss		687 4 6
Net increase in income		£1,515 9 0

FINANCE.		
	£	s. d.
New Fellows, &c.	1,503	
Deaths and resignations	495	
Numerical increase	1,008	
Total on December 31, 1909	11,645	
Total on December 31, 1910	12,643	

FINANCE.

It will be noticed that the accounts are this year presented in a somewhat different form. The trust funds are now becoming so numerous that the Council consider the time has arrived when each of them should be recorded separately and show (in) the manner in which the funds are invested, (2) the income received during the year, and (3) the disposal of the same.

EXAMINATIONS.

The Society's examinations were held for public parks gardeners, school teachers, and in general gardening, the number of candidates being considerably in excess of former years.

COMMITTEES, &c.

The Society owes a constantly recurring debt to the members of the committees, judges, writers of papers for the *Journal*, compilers of extracts, reviewers, lecturers, and the several examiners, who, during the past twelve months have done so much to contribute to the Society's usefulness, and to help maintain its high standing among the practical and scientific institutions of the world.

In consequence of the great increase in the work of the Floral Committee, it has been found necessary to appoint a second chairman, so that one may (as far as possible) devote himself to the plants for certificate, and the other to the groups in the hall.

The Council also acknowledge their obligations to the Press for their invaluable assistance in reporting upon, and calling attention to, the work of the Society.

LIST OF PLANTS CERTIFICATED.

From time to time it becomes necessary to issue a corrected list of plants and fruits Certificated by the Society. A new revision up to December 31, 1910, has been made, and may now be obtained from the office—Orchids, &c.; fruits and vegetables, decorative plants, ferns and flow'rs, &c. It is hoped that Fellows will provide themselves with these necessary records covering the last 50 years.

By order of the Council,

W. WILKS, Secretary.

Royal Horticultural Society

Vincent Square, Westminster, S.W.

December 31, 1910.

Scientific Committee.

JANUARY 31.—Present: Mr. E. A. Bowles, M.A., F.L.S. (in the Chair); Dr. A. B. Rendle, Messrs. J. Fraser, A. D. Michael, J. W. Odell, A. Worsley, E. M. Holmes, W. C. Worsdell, W. Fawcett, A. W. Sutton, and F. J. Chittenden (hon. sec.).

Cutting the Common Reed.—A question was raised concerning whether the best practice in cutting the Common Reed (*Phragmites communis*) was to cut annually or triennially. It was pointed out that in the Norfolk Broads, where this crop is a very valuable one, the practice where the best Reeds were grown was to cut annually, for if they were left longer they became very brittle, and otherwise deteriorated, making the cut sample very irregular.

Cedar cones.—Mr. J. FRASER showed cones of *Cedrus Libani* and *C. Deodara*. These cones had been collected in August, when they were both green. The cone of *C. Libani* was comparatively small, it became brown a month after gathering, and was hollow at the apex. That of *C. Deodara* was heavier and full of resin; it became brown only after two months; the apex of the cone was pointed, and each scale, unlike that of *C. Libani*, was ribbed near the apex.

Double Richardia africana.—Some large and well-marked examples of this well-known phenomenon were sent from Trowbridge.

Fasciation in Marsdenia.—Mr. BOWLES showed a fasciated stem of *Marsdenia erecta* from the Rev. Canon ELLACOMBE, at Bitton. It is rare for an example of fasciation in a plant belonging to the Asclepiadaceæ to be shown before the Committee. Mr. WORSDELL remarked that he had observed the phenomenon in a *Stapelia* in South Africa.

White Crocus Imperati.—Mr. E. A. BOWLES drew attention to a white form of *Crocus Imperati* which had occurred among some imported corms, and was shown by Messrs. BARR. The flower showed none of the barring on the outside of the perianth segments usual in this species.

NATIONAL CHRYSANTHEMUM.

(ANNUAL MEETING.)

FEBRUARY 6.—The annual general meeting of the members of this Society took place on Monday last, at Carr's Restaurant, Strand. The President, Sir Albert Rollit, D.C.L., occupied the chair, the company numbering about 50. Before the business of the meeting was proceeded with Mr. C. Harman Payne offered the congratulations of the members to Sir Albert Rollit on his recent appointment to a First-class Commandership of the Order of St. Olaf, Norway, this distinction being granted by the Norwegian Sovereign in recognition of Sir Albert Rollit's efforts in promoting business relations between this country and Norway, and in the settlement of disputes by arbitration. Sir Albert Rollit expressed his gratification for the kind remarks made by Mr. Payne, and said that the honour came as a surprise, although he was delighted to receive it, and not less the King's permission to accept it. Sir Albert Rollit then formally presented the annual report, of which we give the following extracts:—

EXTRACTS FROM THE REPORT.

The early Chrysanthemum show was held at the Crystal Palace on October 5 and 6, and the grand autumn exhibition also at the Crystal Palace on November 2, 3 and 4. Both shows marked a great advance on previous years, and in the opinion of many experts the November show was in point of quality the finest which has been held under this Society's auspices. The number of exhibits was considerably greater than in 1909, but did not constitute a record. Unfortunately the weather on the second and third days of the November show proved very mild.

Having in mind the great success which attended the proceedings at the Society's Conference in 1909, your Committee arranged for a further Conference in 1910, which was held at Essex Hall on December 5.

The question of publishing a full report of the proceedings of this Conference is under the consideration of your Committee.

Mr. D. B. Crane was unanimously re-elected Chairman of the Floral Committee at the first meeting held in 1910, and as a mark of appreciation of Mr. Crane's long and valued service to the Society he has been nominated for election as an Honorary Fellow at the annual meeting. The Committee met at Essex Hall and the Crystal Palace on eight occasions for the consideration of new varieties. Two hundred and thirty-two novelties were submitted to them, and of these 52 were awarded First-class Certificates, 22 were commended, and one received

the special Award for Colour instituted in 1909. The sections to which certificates were awarded were as follows:—Decorative, 20; Japanese, 19; Singles, 12; Incurred, 2; Semi-double Decorative, 1.

Difficulties have arisen on more than one occasion during the past season with regard to the sections in which novelties should be classified, and the Floral Committee are now taking into consideration the whole question of classification with a view to revising the list of sections, if thought necessary, and defining the characteristics of the various sections with due regard to the advancement in culture which has been made since the Society's catalogue was issued.

In the early part of 1910 the Floral Committee decided to hold trials of single varieties, with a view to drawing up a list of "too-much-alike" varieties, and also of "pointing" the best singles in each shade of colour.

The response was not as large as the Committee anticipated, but, at the same time, was sufficient to enable them to carry out full trials of all the varieties that were worthy of note. A report by the Floral Committee (on these trials) will be issued in due course. The report will contain a list of synonymous or "too-much-alike" varieties, and also a list of the best varieties, together with such other information as the Committee think will be of interest to the members.

FINANCE.—Your Committee have again the satisfaction to report that the whole of the ordinary liabilities of the Society were paid before the books were closed on December 31, 1910. In the early part of the year a sum of £50 was transferred from current account to reserve fund account; and it will be observed from the accounts that at the close of the year a sum of £50 8s. 8d. stood to the credit of the Society on current account at the bank. There are other sundry small amounts due for medals and advertisements, and these, together with the various properties at the Crystal Palace, and the money at the bank, make the total assets on December 31 last £121 12s. 9d.

The annual outing took place on July 25, and the annual dinner on Tuesday, November 29.

In connection with the International Exhibition held at Brussels during 1910, it was felt that a special effort should be made to send an exhibit to Brussels in the name of the National Chrysanthemum Society of England. Arrangements had practically been completed for the staging of an exhibit by this Society when the disastrous fire occurred in the month of August. After the fire the president brought up for consideration a proposition that the Society should send an exhibit of Chrysanthemums in pots. The matter was discussed in considerable detail and an estimate was arrived at of the total expenses. Unfortunately the figure suggested was considered by the Board of Trade to be prohibitive and the matter fell to the ground.

In connection with the International Chrysanthemum Show, which was held at Paris, in November last, the President, also Mr. T. Bevan and Mr. C. Harman Payne, were appointed members of the jury.

Whilst in Paris the President of the Society took the opportunity of presenting this Society's medals to the following three gentlemen:—Mons. Viger, President of the National Horticultural Society of France; Mons. A. Truffaut, Premier Vice-President of the National Horticultural Society of France; Mons. Maxime de la Rocheterie, President of the French Chrysanthemum Society.

Your Committee have had under consideration correspondence from the committee in charge of the arrangements for the International Exhibition to be held at London in May, 1912, and have offered to give National Chrysanthemum Society medals to be awarded to exhibits of Chrysanthemums at the exhibition. The matter will probably be referred to at greater length in the next annual report.

The management of the Crystal Palace being still in the hands of a Receiver, acting under the direction of the High Court, it has not yet been possible to complete the arrangements for the holding of the 1911 shows. Negotiations are, however, now proceeding, and the dates for the shows have been provisionally fixed as follows:—October 4 and 5, November 1, 2 and 3.

The statement of accounts showed that the annual subscriptions in 1910 amounted to £138 3s. 9d. The sum of £150 was received from the Crystal Palace authorities.

Sir Albert Rollit said the report was a record of good work performed by the executive committee, which carries out its labours well under the guidance of its chairman, Mr. Thomas Bevan, and with the assistance of the Secretary, whom he praised highly. The President said that the Society fulfils a useful purpose, and takes its proper place among the various horticultural bodies in this and other countries. The Society was asked last summer by the National Horticultural Society of France to send members to act as judges at the French autumn flower show. The speaker said the reception afforded the deputation, of which he was a member, was most cordial, and that visits such as these do much to promote international goodwill, and assist largely to preserve the peace of the world, objects which he had specially at heart. As their President, he took the opportunity on that occasion to present the Society's medals to the following distinguished French horticulturists:—Mons. Viger,

President of the National Horticultural Society of France, Mons. Truffaut, Premier Vice-President of the National Horticultural Society of France, and M. Maxime de la Rocheterie, President of the French Chrysanthemum Society.

Sir Albert next referred to the need for increased membership, which would not only give them a greater status in the horticultural world, but also increased funds. Referring to the work done by the Society during the past year, he said that the exhibits at their shows were, if not better, as good as ever. The Floral Committee had done good service, whilst the Conference had proved most useful. Referring to the International Exhibition to be held in 1912, he expressed the hope that the National Chrysanthemum Society would be worthily represented. It only needed the united efforts of horticulturists to make the exhibition a great success. The management of the N.C.S. had closed the year without a liability, and there was a reserve fund of upwards of £50, besides a balance at the bankers, which was always admitted to be a test of respectability.

The adoption of the report was moved by the chairman, Mr. Thomas Bevan, who referred to the report as one of the best ever published by the Society. The report and balance-sheet were adopted unanimously. The retiring auditors were thanked for their services, after which Mr. Bevan proposed the re-election of Sir Albert Rollit as President, the motion being seconded by Mr. D. B. Crane. The motion being put to the meeting it was carried with acclamation. The other officers, including the treasurer, Mr. John Green; chairman of committee, Mr. Thomas Bevan; vice-chairman, Mr. E. Hawes; foreign corresponding secretary, Mr. C. Harman Payne; and general secretary, Mr. Richard Witty, were all re-elected. Mr. Witty's good work as secretary was referred to by several speakers, including the President. The committee was also elected; Mr. R. J. Frogbrook and Mr. J. Kirkwood being appointed to fill vacancies.

Sir Albert Rollit next formally asked the member to ratify the gift of medals referred to, and also the election as honorary members of the Society of Mr. J. H. Witty, vice-chairman of the executive committee, and Mr. D. B. Crane, chairman of the floral committee, with M. Louis Gentil as corresponding member.

It was suggested by Mr. Thomas Bevan that some diploma or certificate should accompany the honorary membership, and it was finally decided that the Society's medal, duly inscribed, should be presented in each case.

WOOLTON CHRYSANTHEMUM.

FEBRUARY 1.—The annual meeting of the above society was held on this date, Mr. A. G. Dent presided. The annual report stated that the exhibition was fully equal to the average of the society's shows. Three of the challenge cups had been won outright, and it is hoped to provide others in their places. The finances showed a slight increase in favour of the society. The officials, including Mr. A. G. Dent, Treasurer, Mr. R. G. Waterman, Assistant Treasurer, and Mr. W. D. Skinner, Secretary, were all re-elected.

LIVERPOOL HORTICULTURAL.

The 32nd annual general meeting of this society was held recently, Mr. W. Mercer presiding over a small attendance. The report stated that the three exhibitions were, in each case, of high merit. The principal items in the statement of accounts were (receipts) subscriptions, £292 10s.; admissions to shows, £143 4s. 11d.; special prizes, £37 15s. 6d.; and entrance fees, £15 1s. 6d., and (expenditure) prize money, £220 3s. 6d. The society commenced the year with a balance in hand of £220 8s. 6d., and closed with a balance of £172 10s. 8d., the deficit being due to the holding of an extra show.

EDINBURGH MARKET GARDENERS.

FEBRUARY 3.—The annual dinner of this association was held in the Royal British Hotel, Edinburgh, on this date. Mr. King, the president, occupied the chair, and the company numbered between 40 and 50. Mr. Morrison, Musselburgh, who is leaving to engage in market gardening in the Birmingham district, was presented, at the meeting, with a roll-top writing desk.

VENTNOR HORTICULTURAL.

JANUARY 23.—The annual meeting of the Ventnor and Undercliff Horticultural and Chrysanthemum Society was held in the Town Hall, Ventnor. Mr. G. A. S. Saunders occupied the chair. The hon. secretary presented the balance-sheet, which showed funds amounting to £56 16s. 3d. After meeting all expenses, which totalled £44 10s. 1d., the balance in hand was £12 6s. 2d. Mr. McDougall was re-elected president. The vice-president, committee, secretary, and other officials were re-elected. It was decided to hold the annual show on Tuesday and Wednesday, November 7 and 8. The chairman raised the question of having a summer show, which was dropped last year, because the society could not afford it. Mr. Attrill moved that a spring show should be held. The chairman suggested the appointment of a small committee to ascertain what support they would be likely to get. Mr. Sheath seconded, and the motion was carried unanimously.

ROYAL SCOTTISH ARBORICULTURAL.

FEBRUARY 3.—The annual meeting of this society was held at 5, St. Andrew Square, Edinburgh, on this date. The president, Sir John Stirling Maxwell, Bart., of Pollok, presided, and there was an attendance of about 50 members.

The report by the council showed that there was an increase of 17 in the membership as compared with 1910, and that it now stands at 1,569. The excess of income over expenditure for 1910 was £129, and the funds amounted to £2,200.

In his address, the chairman made some stringent remarks regarding the treatment of forestry by the Government. There was no department of forestry, and all their difficulties sprang from their inability to persuade the Government that such a department was necessary. Money had been devoted by Parliament, under the Development Act, for forestry purposes, but the Development Commissioners had to be approached through the Scottish Education Department. The assistance of the society had been solicited, but this, he thought (and the council agreed with him), should not be given unless they obtained some definite assurance that, when the grant was given for the development of forestry it would be entrusted to men who were competent to administer it, and until they had a guarantee that the survey which the society had commenced would be taken up at once by the Government. The society had commenced the survey with the object of advancing afforestation in Scotland, and it would be foolish at this time to give their assistance unless they knew that an effective policy would be pursued. Without such assurances, it would be better for them to abandon their position as helpers and become instead formidable critics.

Lord Lovat made a statement regarding the sample survey which he and Captain Stirling had undertaken, from which it appeared that in the Loch Ness Valley there were 60,000 acres which could be planted with trees.

It was intimated that the excursion this year would be to the border districts, and that the society would have a forestry exhibit in connection with the Scottish Exhibition to be held in Glasgow this season.

Sir John Stirling Maxwell was re-elected president, and Dr. Borthwick and Mr. Sydney Gammell, of Drumlochty, vice-presidents.

Mr. A. T. Gillanders, F.E.S., author of *Forest Entomology*, was elected an honorary life member of the society.

A lecture on "The State and Private Woodlands" was afterwards delivered by Mr. Wm. Dawson, M.A., B.Sc., Lecturer in Forestry, Marischal College, Aberdeen.

BRITISH GARDENERS' ASSOCIATION.

A MEETING of gardeners will be held at the Cobden Café, Corporation Street, Birmingham, on Saturday next, February 18, at 7.30 p.m., to re-organise the local branch of the association. Since the meeting held on January 21 a large number of gardeners in the Birmingham district have joined the association, and the branch now promises to be one of the strongest and most enthusiastic in the country. The local secretary is Mr. J. D. Jones, 8, Acacia Road, Bournville, Birmingham.

ABERDEEN CHRYSANTHEMUM.

FEBRUARY 4.—The annual meeting of this Society was held on this date, Mr. A. M. Cocker, of Messrs. Cocker & Sons, Sunnyside and Springhill Nurseries, Aberdeen, vice-chairman, occupied the chair. The secretary, Mr. M. H. Sinclair, submitted the annual report and balance-sheet, which showed that there was a loss on the year's working of £27 15s. 3d., due chiefly to unfavourable weather on the occasion of the annual show.

In moving the adoption of the report and accounts, the chairman expressed his confidence in the future welfare of the society. He hoped it would continue for many years to do useful work in horticulture. Mr. J. Smith seconded, and the motion was carried. Miss Chalmers, of Ardbeck, and the Right Hon. Robert Fergusson, of Finzean, were added to the list of hon. vice-presidents. Lord Provost Wilson, of Aberdeen, was re-elected hon. president. Mr. W. J. Middleton was re-elected chairman, and Mr. A. M. Cocker, whose ungrudging and devoted services to the interests of the society are very highly appreciated, was re-elected vice-chairman. A committee of 20 was also elected. The secretary, Mr. M. H. Sinclair, was also re-elected. It was decided to hold the annual show in the Music Hall Buildings, Aberdeen, on November 24 and 25.

Obituary.

MRS. SUTTON.—Our readers will sympathize with Mr. Martin J. Sutton, of Holme Park, Sonning, Berkshire, and head of the firm of Messrs. Sutton & Sons, seedsman, Reading, in the death of his wife, which occurred last week. The funeral took place at St. Andrew's, Sonning, on Monday last, in the presence of many relatives and a very large gathering of people from all parts of the county. Mrs. Sutton was held in the highest esteem by all who knew her, and this esteem found expression in the attendance at the funeral of numerous deputations from religious, philanthropic, and educational institutions with which Mr. and Mrs. Sutton have been associated. The vault was lined with white and salmon-colored Cyclamen and Ivy, and the coffin bore but one tribute, namely, a large Palm leaf from the bereaved husband.

UHEI SUZUKI. We regret to announce the death of Mr. Uhei Suzuki, the founder of the Yokohama Nursery Co., Japan. Born in a country district in Japan, he went to Yokohama. Later, he was appointed head gardener to an English nobleman residing in Yokohama, who was a lover of Japanese gardens and horticulture. Mr. Louis Boehmer settled in Yokohama, and started to export Lily bulbs to Europe. Mr. Boehmer engaged Mr. Suzuki, and began to export bulbs in large quantities. Later, Mr. Suzuki commenced business for himself, founding, as stated, the Yokohama Nursery Co.

FREDERICK DORNER.—The American papers announce the death of Mr. Frederick Dorner, nurseryman, of Lafayette, Indiana, U.S.A. Mr. Dorner was a well-known cultivator of Carnations, and raised many varieties of the perpetual-blooming type. He was a native of Baden, Germany, and emigrated to America in the '50's, spending part of his time farming and part as a florist. In 1870 he commenced business as a florist at Lafayette. About 1889 he turned his attention to the raising of Carnations. It is said that he raised as many as 5,000 Carnation seedlings in one year. Mr. Dorner was also a grower of Chrysanthemums, and he raised many new varieties.

LEON VAN DEN BOSSCHE.—M. Leon van den Bossche, late Belgian Minister at Constantinople, died on the 31st ult., in his 70th year, at Tirlemont, Belgium, his native town. In the latter years of his life, M. Van den Bossche showed a remarkable interest in botany and horticulture. He devoted himself to the study of these subjects with extraordinary zeal, and, owing to his great wealth and wonderful activity, he was able to get together a very important collection of exotic plants and a herbarium of great scientific value. In 1893, the Castellon of Tirlemont published a

list of the trees and shrubs cultivated in the gardens of M. L. Van den Bossche, and a second edition of this work appeared in 1900. The deceased, with the collaboration of M. Em. de Wilde, edited the *Icones selecta horti Thencensis* and the *Planta nova vel minus cognita ex herbaria horti Thencensis*. Since 1899, six volumes of the *Icones selecta* have appeared, with 240 plates. Two volumes of the *Planta nova*, with 90 plates, have been published since 1904. All the plates have been reproduced from drawings by M. Maur. d'Apraval, a skilled Parisian draughtsman. It is to be hoped that in the interests of science the beautiful collections formed by M. Van den Bossche will still be preserved.

GARDENING APPOINTMENTS.

- Mr. W. F. WRIGHT, late Gardener at Caer Ebor, near Monmouth, and Clodd in Hill, Leebeck, near Monmouth, as Gardener to Capt. A. V. BISSONNETTE, Esq., The Florence, St. Braxels, Gloucestershire.
Mr. J. MAKESZIL, for 2 years and 9 months Foreman at Bawley Manor Gardens, Woodbridge, Suffolk, as Gardener to Capt. J. G. DUGDALE, The Abbey, Gloucester.
Mr. F. ZORER, for the last 3 years Foreman at Elford Park, Farnham, Surrey, as Gardener to G. BERT, Esq., J.P., Castle Hill, Rotherfield, Tunbridge Wells.
Mr. F. I. KRISTOF, for the past 6 years Foreman in the Pleasure Grounds at Hartham Park, Wiltshire, as Gardener to F. A. HASKELL, Esq., Notton House, Lacock, Chippenham, Wiltshire.
Mr. C. JONES, late Foreman at Nash Court, Faversham, as Gardener to J. B. DE VRIES, Esq., Holmbourne Manor, Kent.
Mr. W. FLESHAD, for the past 7 years Assistant Superintendent of Parks and Recreation Grounds, Leicester, as Superintendent of Parks and Open Spaces for the Corporation of Wolverhampton. (Thanks for 2s. for the R.G.C.F. box.—L.S.S.)
Mr. WM. STANFORD, late Gardener to A. HENDERSON, Esq., Fairmile Court, Cobham, Surrey, as Gardener to JAMES NEWSLEAD, Esq., West Ashby Manor, Harrogate, Lincolnshire.
Mr. HENRIET BACKGATH, for the past 4 years employed in Hartham Hall Gardens, as Gardener to SIR H. MELBURY, Bart., Pipewell Hall, Kettering, Northants.

DR. RICHARD E. KEENE, Phoenix, Arizona, U.S.A.—Cacti.

The Editors will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for reproduction in this Journal.

- ANCHUSA ITALICA: Enquirer. As your plants are old, you should certainly lift them and divide the roots, retaining the strongest to plant in fresh soil. This plant delights in a moderately light, rich and deeply worked soil.
AUBERGINES: Constant Reader. If you intend to exhibit a large collection of vegetables, Aubergines would furnish a good dish, but it would be better not to include them in a small group.
BELLFINCHES DESTROYING FRUIT BUDS: M. P. In the issue for February 16, 1907, p. 106, a correspondent recommends spraying the trees with gas tar and water as a preventive against

birds attacking the buds. The mixture is made as follows:—Place a quantity of newly-made tar in an old iron pan, half fill it with tar and half with water. Leave this undisturbed for 48 hours. One gallon of the water only (the tar must not be disturbed) should be mixed with 4 gallons of soft water, and the trees syringed with this mixture. In time the unpleasant smell is lost; then make another application of the mixture. The tar may be covered with water several times, and must be stirred occasionally in order to allow the water to become impregnated with the gases.

CORRECTION. The hybrid Cyripedium from C. glaucophyllum and C. bellatulum is named Charles Sladden (or Sladdenii), not "Sladdin," as printed on p. 50.

GRAFTING THE ORANGE: P. G. W. The Orange is usually worked upon the Lemon. Stocks are raised from seeds, and when two years old they are grafted. This work is performed under glass, and the plants are kept in a close propagating frame in a warm pit. They are covered with material to exclude the light. Ventilation is given after a time, and bottom heat is afforded for several months. Your seedling Oranges would flower earlier if they were grafted, selecting the scions from mature trees that have reached the flowering stage.

INSECTS ON ROOTS OF ADIANTUM: G. H. S. The white, filamentous insect living on the roots of your Adiantum Ferns is Ripersia terrestris, a near relative of Mealy-bug. Apply carbon bisulphide, making holes in the soil with a piece of wire, using about one teaspoonful of the liquid to each small pot.

LEGGY RHODODENDRON: W. E. If the plant is not very old, you may cut it back, with good prospects of shoots breaking freely. Success however, will largely depend on the condition under which the plant is growing and the amount of pruning that is required to bring the plant to a proper shape.

NAMES OF FRUITS: Correspondent. 2, Flower Kent; 4, Franklin's Golden Pippin.—Highgate 1, Dumelow's Seedling (Wellington); 3, Warner's King; 7, Blenheim Pippin; 9, Claygate Pearmain; 10, Cox's Orange Pippin; 11, Lane Prince Albert.

NAMES OF PLANTS: W. H. C. 1, Crataegus Biebersteini; 2, Saxifraga hypnoides; 3, S. cuspitosa; 4, Atriplex Halimus; 5, Thuya plicata; 6, Cupressus Lawsoniana lutea.—H. Clements. The Pelargonium (Geranium) leaf is similar to several varieties obtained by crossing the Ivy-leaf and Zonal sections. Until the plant flowers, it will be impossible to say whether it is a distinct variety or not.—G. I. The scented Pelargoniums are as follows: capitatum var. Unique; 2, capitatum; 3, crispum major; 4, viscosissimum, Phœasant foot var.; 5, Mrs. Kingsbury; 6, Attar; 7, Pretty Polly; 8, Little Gem; 9, Fragrans; 10, Shotesham Pet; 11, tomentosum; 12, Lady Scarborough; 15, abrotanifolium 14, this plant is Cytisus racemosus var. Atkinsii.—F. P. 1, Lastrea dilatata; 2, Asplenium trichomanes; 3, A. viride; 4, Adiantum hispidulum.—Pat. 1, Garrya elliptica; 2, Eriobotrya japonica; 3, Buddleia glabra; others next week.—H. 1, Skimmia japonica; 2, Picea nobilis; 3, Pseudotsuga Douglasii; 4, Abies nobilis; 5, Pinus Strobus; 6, Tsuga Pattoniana; 7, Cryptomeria japonica

PEACH-BUDS DROPPING: Nectarine. This is the result of some check to the tree, and it may be due to the root pruning every alternate year. In order to check the excessive growth of the tree, without resorting so frequently to root pruning, lift the plant next season and restrict the rooting area, mixing a quantity of mortar rubble in the soil. You do not state the variety; some sorts of Peaches are more liable to bud-dropping than others.

SALE OF SEEDS: Law. Your only remedy is to proceed through the county court for the recovery of the debt.

THE MARKET FRUIT GARDEN.

THE second half of January proved to be the best period for the planting experienced this season, though it may be said that "bad was the best." The land had not dried sufficiently after rain on 10 out of the first 12 days of the month until about the 16th, and then, such land as is at all heavy was tough, and also wetter than could have been desired. On the 30th a stop was put to the work by frost for a few days; but mild weather, without rain, has set in since, and the land now works better than it has done at any previous time since the planting season began.

In my last notes it was remarked that, although the keeping of Apples had not paid well up to the end of December, growers who were holding their fruits for January would probably obtain good prices before the end of the month. This anticipation was realised, as good cookers have been quoted recently in London up to 9s. a bushel, Dumelow's Seedling (Wellington) touching 10s. The conclusion seems to be that only the best keepers should be held after November, and that these should be kept until January. English dessert Apples appear to be "conspicuous by their absence" from the markets.

There are but few dessert Apples which do not lose much of their flavour by being kept after Christmas. Charles Ross, I find, should not be kept after November, as it loses nearly all its flavour, becomes mealy, and begins to rot at the core after that month. According to my observations, the best Apples for retaining flavour when kept till January or later are Cox's Orange Pippin, which is always delicious; D'Arcy Spice (otherwise Baddow Pippin), Cornish Aromatic,

Duke of Devonshire, and Magnum Bonum. The last, which is not in Hogg's *Fruit Manual*, is one of the most aromatic of Apples. I am not sure as to its keeping limit, but doubt if it is long after the beginning of January; nor do I know anything about it, except the enjoyment of eating it. Duke of Devonshire will keep until May, although its spicy flavour may become less marked after January, but much depends upon the time of gathering. It is one of the most regular of croppers with me, and probably it would pay to grow for market if planted thickly, as it is of upright habit, and a feeble, though healthy grower. D'Arcy Spice is a good cropper in Essex, but fails to grow properly in my present place in Sussex.

Newton Wonder, perhaps the best of all long-keeping culinary Apples, is the most economical in use so far as my notice has extended, because it requires little or no sugar. It is one of the few Apples which, when baked without a crust, can be eaten without sugar by one who does not like sour fruit. It is also one of the richest cooking Apples for pies, stewing, or for making sauce. Moreover, at this period of the year, it is more juicy and pleasant to eat raw than many dessert Apples.

DRAWBACKS TO FRUIT CULTURE.

The growing of Corn and of fruit alike would be more or less satisfactory if it were not for a field of Corn or part of a fruit plantation falling so far below the average as to be nearly a failure. One may have to dig up an acre of Apple trees because they have become poisoned with canker, in spite of all efforts to restrict its spread, or a field of Gooseberries in consequence of an attack of American mildew, or, as in my case, of some mysterious disease called Collar Rot by one authority and Botrytis by another. These are extreme cases, and those of less complete failure are much more common. It is a rare orchard, if of any considerable size, in which some varieties of Apples or Plums are not found to be doing poorly. Two speakers, at a recent conference, defended Worcester Pearmain against the charge of being a "worn-out" variety. It must be admitted that the variety grows feebly on some soils. Apparently it prefers heavy to light land, for a friend whose soil is a stiff one over the London clay has a large number of Worcester Pearmain trees of great size, and finds the variety the most profitable of all the many Apples which he grows. With me it is a good and regular bearer, but not a free grower on a lightish soil, and in a part of one field its behaviour is so unsatisfactory that a good deal of grubbing-up will be done next autumn or winter unless much improvement takes place as the result of severe pruning. The faulty trees were planted five years ago, and they are a mass of fruit buds and twiggy growth, although they were cut back moderately in their early stages. Moreover, they have nearly as much canker showing in fruit spurs and bases of side shoots, and even bases of both leaf and fruit buds, as Cox's Orange Pippin. This canker is not the result of neglect, as much of it is on the new wood, and, every observed sign of the disease-spot has been dealt with from its first appearance. There is clear enough proof that canker is something more than a wound parasite, for last season there was no aphid attack to cause wounds in buds and fruit spurs. The infection must in some way travel up the shoots to allow of the disease breaking out as it does. In the best and most sheltered part of the field there are some fine specimens of Cox's Orange Pippin. A "fly in the ointment" with me is the existence of a large number of Duchess

of Oldenburg trees, which I was induced to raise and plant by a statement made to me by a very successful grower of Apples on a large scale. In reply to an inquiry as to which variety of Apple he found the most profitable, he replied, "Duchess of Oldenburg." Well, it is a good cropper, but the fruit is not nice enough for dessert or big enough to sell well for cooking, and, healthy young trees though they are, these Duchess trees will possibly be grafted with another variety next March.

A GOOD MANURE MIXTURE FOR FRUIT.

A dressing at the rate of 8 cwt. per acre, made up of two parts high grade superphosphate and one part each of sulphate of ammonia and muriate of potash, was applied last spring to a large patch of Black Currant cuttings, one small piece getting no manure. In the autumn the young bushes developed from the cuttings on the manured piece were fully double the size of those grown without the manure. The former as yearlings were as large as the best of some two-year-old bushes purchased. The land had received fully 10 tons per acre of chalk a year before, otherwise the sulphate of ammonia would not have acted so well, as the soil is naturally deficient in lime, of which sulphate of ammonia is an exhauster. The same mixture was also applied to a plantation of Apples and Black Currants planted three years before. It had a good effect upon the bushes, as shown by one row from which it was omitted; but no decided effect is noticeable in the trees at present. The mixture has been used for years for Potatoes, the yield of which, as compared with unmanured pieces, it fully doubles when no farm-yard manure is applied. Sometimes sulphate instead of muriate of potash has been used with about the same results. *A Southern Grower.*

ORCHID NOTES AND GLEANINGS.

COLLABIUM NEBULOSUM.

A FINE inflorescence of this singular terrestrial Orchid is sent by Sir Jeremiah Colman, Bart., Gatton Park, where it has been in flower for a considerable time, and probably for the first time in England.

The plant has fleshy stems, about 2 inches in height, bearing a single leaf on a rounded petiole, the blade being broadly ovate, acuminate, plicate; the pseudo-bulb and leaf-stalk are tinged with purple, and the leaf mottled with light and dark green. The stout, erect scape, some 2 feet in height, is purple, and bears numerous flowers, each about half-an-inch in length. The sepals are greenish, and continue into a pronounced mentum or spur. The petals are rather lighter, and both possess reddish edges. The column is simple, twisted. The singular trilobed, clawed lip is white and slightly fringed. The flowers are arranged in scattered, irregular whorls.

It is a very remarkable species of the order and most nearly allied to *Chrysoglossum*.

The plant was imported from Java as *Pleoclotis javanica*, and received a Botanical Certificate at the Royal Horticultural Society, subject to its correct identification. Examination shows that while bearing a fair resemblance to *P. javanica*, it differs therefrom in its botanical characters: thus *Pleoclotis* has no spur, while the spur of *Collabium* is highly developed.

MORMODES COGNIAUXII.

AN inflorescence of a light form of this interesting orchid is sent by Mr. F. Mimms (gr. to W. E. Balston, Esq., Berwin, Porter's Bar), who states that the plant has four similarly large spurs and two smaller ones.

This variety is lighter in colour than the type illustrated in *Lichnera*, vol. x., but is otherwise

similar. The stout spike bears 16 blooms, each an inch-and-three-quarters in length. The sepals and petals are greenish-white, tinged with rose, and uniformly striped with purple; the column and stalked labellum are rose-pink, the sides rolled back, forming a trumpet-shaped front, and bearing a short apiculus.

It is of *Mormodes Baccinator* section, and probably very variable in colour like that species.

BRASSO CATTLEYA VILMORINIANA

(C. MOSSIE \times B.C. MRS. J. LEEMANN).

This pretty novelty was shown by Monsieur Chas. Maron, Brunoy, Seine et Oise, France, at a recent meeting of the Société Nationale d'Horticulture de France.

It is a flower of good shape and texture, openly displayed, the sepals and petals magenta-rose, and the well-rounded lip rather deeper in colour than the other segments, and veined with purple in front, the tint of the veining being as bright as in a good form of *C. Mossie*. The disc is yellow, and the whole flower distinct and attractive.

ODONTOGLOSSUM HARWOODII.

This fine variety of *Odontoglossum* was awarded a First class Certificate by the Orchid Committee of the Royal Horticultural Society on the 31st ult. It was obtained by crossing *O. Wigandianum* and *O. maculatum auriferum*, the raisers being Messrs. Charlesworth & Co., Haywards Heath. The colour of the flower is a clear buttercup yellow, with a lighter shade in the centres of the broad sepals and petals, which are spotted with dark claret colour. The variety represents one of the finest hybrids of *O. maculatum*, being superior even to the variety that attracted such notice at the last Ghent Quinquennial Show.

THE BULB GARDEN.

COLCHICUM HYDROPHILUM.

COLCHICUM HYDROPHILUM was introduced from Asia Minor by Mr. Siche, of Mersina, and is proving useful for early-flowering. The mild winter has proved congenial to the plants, which have been in bloom in my garden since early in January. Lack of sunshine prevented the blooms from opening fully, but they were pleasing with their rosy-purple segments forming almost a cone. The blossoms have a much shorter tube than those of most *Colchicums*, and this enables them to withstand bad weather better. So little colour is seen in the garden in January that a clump of this *Colchicum* is doubly acceptable.

CLINTONIA BOREALIS.

THERE is apparently some confusion in nurseries respecting the colour of the flower of *Clintonia borealis*, an interesting North American plant. In some catalogues it is described as having rosy flowers, whereas they are of a greenish-yellow. I imagine that the plant described as "rosy" must be *C. Andrewsiana*, a Californian species. *C. borealis* is a native of the moist woods and thickets of North-east America from Newfoundland to Ontario and Minnesota, extending southwards to North Carolina and Wisconsin (see Britton & Brown's *Illustrated Flora of the Northern States and Canada*, I. p. 428).

C. Andrewsiana has been catalogued in this country, but the plant does not appear to be perfectly satisfactory in the colder districts, unless protected in winter and early spring. It is a prettier plant than *C. borealis* and deserves the notice of those who admire the less important members of the great Lily family, to which it belongs. It is taller than *C. borealis*, which grows about a foot high. Both species, together with *C. umbellata* (*umbellulata* of Michaux) and *C. uniflora*, appear to be in cultivation at Kew. S. Arnott, *Sunnymead, Dumfries*.

NOTICES OF BOOKS.

A NEW WORK ON BRITISH FORESTRY.*

IN view of unduly favourable estimates that have been published by a small minority among enthusiasts advocating a comprehensive scheme of afforestation in the British Isles, a judicial and reliable work giving a restatement of the whole case would not be superfluous. But those who look for such a reasoned judgment in the pages of Mr. Forbes's book will be disappointed. Apart from the author's controversial methods, which are to be deprecated, it is not easy to reconcile his conclusions with the facts and principles involved. This refers particularly to the two chapters (pp. 87-147) dealing with "Climate and Tree-growth" and "Soil and Surface," respectively, which are specially selected for review here, because the subjects treated form the essential basis upon which afforestation rests. If the fundamental conclusions in this section of

which extends from spring to autumn in the case of deciduous trees, and, to some extent, through winter in the case of conifers in the lowlands of at least parts of England and Ireland. Hence the author's arguments as to the rate of production of timber, based upon the temperatures during June, July, and August at different places in the British Isles and on the Continent are delusive, because they neglect the consideration of the length of the assimilating season. It is worthy of note that, in this latter respect, British trees, and especially evergreen conifers, may have often a clear advantage over Continental trees. Again, the author, in discussing the rate of production of timber, comes to an unjustifiable conclusion that after the first 20 years of its life a British tree, and, consequently, a British forest, will produce less timber per annum than a Continental tree, because "persistent clouded sky and the absence of intense isolation tend to check the height, growth, and development of most species."

FIG. 51.—ODONTOGLOSSUM HARWOODII: FLOWER YELLOW, WITH DARK PURPLE SPOTTING.

the work cannot be admitted, then an examination of the author's financial views and detailed considerations becomes useless, so far as the main question of the prospects of forestry in the United Kingdom is concerned.

It must be pointed out, in the first place, that Mr. Forbes seems to have hazy impressions as to the physiological principles underlying the production of timber. In particular, he does not appear to realise the inward and vital significance of the wide difference between the "growing season" and the "assimilating season" of trees. The former is the relatively short season during which the twigs elongate and stems thicken, and is not, as Mr. Forbes assumes, represented by the months of June, July, and August, but mainly by spring and early summer. The food material for this growth is, however, prepared during a much longer period—the assimilating season—

* *The Development of British Forestry*, by A. C. Forbes. (London: Arnold, 1910.)

Apart from the fact that it is diffused light—not direct light—which is the best suited to a tree, it may be pointed out that frequent direct isolation may be a grave disadvantage to Continental trees, not only by necessitating the closure of the stomata of exposed leaves and the consequent partial cessation of the manufacture of food material, but also by causing rapid transpiration that may culminate in leaf-shedding or even desiccation. But the question is too complex for detailed discussion here, as it involves, among other things, the question of the difference of the arrangement and structure of the leaves under different conditions. What is wanted before confident assertions can be made is comparative measurement of British and Continental trees; yet even that is not sufficient, as a quality of the resultant timber steps in as an economic factor. Quite unjustified, too, is Mr. Forbes's statement that in Britain "it is practically certain that conditions are rarely favourable enough for the [annual] growth of timber

trees to be completed in six weeks"; whatever meaning is attached to "[annual] growth," it would be nearer the truth to replace the word "rarely" by "everywhere," as the author is referring to climate. Before passing away from this aspect of the subject, reference may be made to the sentence (on p. 89): "The principal climatic factors in promoting tree growth and timber production may be considered to be sufficient heat and moisture during the growing season." This statement might lead the lay reader to suppose that there must be an adequate rainfall during the growing season, or even during the summer (though the author does not say so), and this is especially probable when coupled with the statements on p. 96, where stress is laid on the rainfall in summer, as a decisive factor determining tree growth in the British Isles. It should be pointed out, in regard to the supply of moisture, that three factors which vary independently are of importance in determining the growth and kind of trees present: (1) the amount of annual rainfall; (2) the relative humidity of the atmosphere during the assimilating season; (3) the rainfall during the assimilating season. The fact is that lofty forests flourish in regions where the rainfall in summer is exceedingly scanty, and far less than in any place in the British Isles. The fundamentally important factor for tree-growth is the aggregate rainfall of the year. For the successful growth of our deciduous trees, and probably for a number of conifers, another factor of importance is the relative humidity of the atmosphere during the summer; the rainfall may be quite small so long as the air is moist enough. We cannot agree with Mr. Forbes that: "For the majority of conifers, however, a summer rainfall of not less than 9 or 10 inches is necessary to produce good growth, unless the soil is naturally damp or cool."

To resume the general consideration of the work under review: the author gives an account of the evil effects of wind in this country that requires serious qualification; this matter is of importance, because it gravely affects the question as to the suitability for afforestation of mountain slopes, where so much land is available for the purpose. Mr. Forbes does not appear to realise that the precise effect of wind depends not merely on its prevalence, but also upon its strength and relative humidity. Further, in contrasting the British Isles with the Continent, as regards the altitudes at which forests can be successfully grown, he makes no attempt to show that winds in the former actually or even probably have a greater drying effect than in the latter. Moreover, we cannot admit the accuracy of the following statement: "Examine any wood, clump, belt, or single tree on a western or southern slope within 50 or even 100 miles of the western coast-line of Great Britain, and one invariably finds . . . dwarfed, stunted, and leaning habit of growth." The same impression on the part of the author dictates his statement: "The general effect of such exposure is that mountain land in Great Britain and Ireland is incapable of growing large timber above 700 or 800 feet, apart from glens, exceptionally good soil, or eastern aspects."

In fact, as regards climate and tree growth in these isles, we do not think that Mr. Forbes's conclusions merit acceptance.

Nor can the author's ideas on the nature and effect of soils be accepted. He generally fails to disentangle clearly the effects of climate, especially wind, and of soil; see, for instance, his discussion on the afforesting of mountain slopes. It is certainly true that on many exposed sites where the soil is shallow, large timber cannot now be grown, but here it is often the unsuitability of the soil that is the cause of the impossibility. Such a defect is less serious than a great climatic defect—for it can be ameliorated by preparatory crops, just as the hostile influence of wind can be mitigated by the establishment of woodlands of increasing height. But

Mr. Forbes seems to estimate at a relatively low value both these methods of amelioration. In fact, he goes to the length of stating that "there is probably no good reason for the assumption that afforestation can do more than increase the fertility of a poor soil by a very small, and, in many cases, inappreciable, extent." Whatever meaning be attached to the term "fertility," this statement is amply disproved by the succession of plant formations on bare rock, on sand dunes, and even on spots in semi-deserts, where trees ultimately grow, as well as by numerous analogous cases of artificial afforestation. The improving effect of a crop of trees varies greatly with the species of trees, site, soil, and geological nature of the subjacent rock, but there is no doubt that, for instance, poor, shallow, or purely mineral soils may be vastly improved by the deposit of humus, by the disintegration of subjacent stones and rocks, and by the incidental introduction of animal or vegetable organisms living in the soil. The author arrives at the conclusion that profitable afforestation is impossible at British altitudes exceeding 1,000 feet, also because of the nature of soil, which he describes as follows: "A layer of wet, spongy peat usually covers the natural soil, on the surface of which Sphagnum and other mosses, Lichens, &c., mixed with coarse grass or bog Myrtle, usually predominate." This passage causes one to be surprised at the author's ideas of the constitution of our mountain soils at altitudes above 1,000 feet, rather than at his pessimistic conclusion based thereon.

In conclusion we may add that inasmuch as Mr. Forbes enjoys a wide and well-deserved reputation as a forester, and inasmuch as he occupies an important position in the Department of Agriculture for Ireland, his views are likely to have considerable influence in determining the fate of afforestation in that country. Hence, it is a matter of no ordinary importance to indicate, as we have attempted to do, wherein the principles which guide Mr. Forbes to his conclusions are, as we think, at variance with our knowledge of the physiology of trees.

The work is illustrated by a number of well-reproduced and interesting photographs of woodlands and trees growing on various sites in the British Isles. *Percy Groom.*

FLORESTS' FLOWERS.

NEW SWEET PEAS FOR 1911.

It has been suggested to the writer that he might suggest a few of the best novelties to be grown in addition to the list of 12 varieties which he gave in the issue for January 21. Naturally one turns to the varieties which have been recently honoured with certificates by the Royal Horticultural Society and the National Sweet Pea Society. First and foremost among these is the Silver Medal variety of 1910, Stirling Stent, but it is now impossible to procure seed of this. The supply was nothing like equal to the demand. Instead of Stirling Stent, Earl Spencer might well be grown. It received an Award of Merit from the Royal Horticultural Society when shown by Messrs. Dobbie & Co. In colour it closely approaches Stirling Stent. It was originally raised by Mr. Silas Cole, Earl Spencer's gardener, but it is now in several hands. Two varieties which received awards from the National Sweet Pea Society, namely, Masterpiece and Mrs. Hugh Dickson have been referred to already. Arthur Green, another of Messrs. Dobbie's introductions, is distinct, but in the opinion of the writer will never be a popular flower, and certainly has no claim to be considered decorative. Cherry Ripe (Gilbert & Son, Bourne) is a Spencerised form of Cocinea, and if it proves a vigorous grower will be a welcome addition. Several good varieties which obtained awards from the National Sweet Pea Society in 1909 were not widely distributed until this year,

owing to short crops of seed in 1909. Notable among these is Charles Foster, introduced by Mr. Bolton, Warton. It is most distinct in colour, being a metallic pink with a sheen of lilac over it. Dazzler from Mr. Breadmore, Winchester, is an improvement on St. George, and a most glowing flower as its name indicates. Edrom Beauty, from Messrs. Dobbie & Co., is an improvement on Helen Lewis in many ways. Mr. Unwin, of Histon, is responsible for the finest striped flower yet introduced, namely, Mrs. W. J. Unwin. These might all be termed 1909 varieties offered freely now for the first time, and they are all well worthy of a trial.

A remarkably fine dark variety is Nubian, of Messrs. Isaac House & Son, Westbury-on-Trym. It has been placed at the top of the dark or maroon section of the National Sweet Pea Society on account of its purity and rich chocolate coloring. Two very charming varieties come from Miss Hemus, and they have received the Award of Merit of the Royal Horticultural Society. Paradise Apple Blossom is white, with a deep edge of pale rose, and Paradise Cerise is, as the name also indicates, a warm cerise-coloured flower in the way of Zarina or Queen of Spain Spencer. Another variety which was honoured by the Royal Horticultural Society is named Elfrida Pearson. This was exhibited by Messrs. J. R. Pearson & Sons, Lowdham. Elfrida Pearson is claimed to be superior to Princess Victoria and Mrs. Harcastle Sykes; from what the writer has seen of it he thinks that this claim will prove to be correct.

The Royal Horticultural Society's Award of Merit was also gained by Thomas Stevenson, a glorious, orange-coloured flower, which is being sent out by Messrs. Sydenham, Birmingham, and by Ivanhoe, a warm-toned lavender flower (Messrs. Dobbie, Edinburgh).

From this list of novelties it will not be difficult to select half a dozen for trial, and the grower will doubtless be guided in his selection by his taste and fancy for particular colours. All the flowers are of the waved type. *A. B. C.*

MARKET GARDENING.

GOOSEBERRY PLANTING.

NOTWITHSTANDING the spread of American Gooseberry-mildew, the planting of Gooseberry bushes is on the increase in this district where few persons are cultivating Black Currants owing to trouble caused by big-bud. Gooseberries furnish an excellent crop for undergrowth to plantations, and whilst the trees are coming into bearing the Gooseberry bushes prove remunerative. The market growers do not cultivate many varieties. Whinham's Industry is the favourite sort, but some are growing "Careless," and others Cousin's Seedling. Other popular market sorts are Keepsake and Crown Bob. The demand for Gooseberries by the makers of preserves was good last season, and has no doubt stimulated the growers to further planting.

ROOT-PRUNING IN MARKET GARDENS.

Root-pruning is little practiced by market growers, but the work well repays the trouble. Any Apple or Pear tree which, whilst growing well does not give a satisfactory crop, should be root-pruned at once. The current year's supply of fruit is not endangered by judicious root-pruning, though the fruit may be smaller. A 14-year-old tree of Bergamot Pear which, although it flowered, never set fruit until root-pruned 50 years ago, has since borne a crop annually. In no instance have I ever had to root-prune the same tree a second year, unless the tree was to be lifted. My plan is to open a half-circular trench around the tree, and cut away the tap roots, filling in the trench with good soil. *Stephen Castle, Walspole St. Andrew.*

THE ALPINE GARDEN.

HOW TO BUILD A MORAINE.

A **MORAINE**, such as the many lateral ones which are found just below the Wellhorn, and close up to the rugged ice-fall of the Rosenlauf Glacier, which comes down from the Wellerhorn, in the Bernese Oberland, consists of broken stones, that have been pounded apart by glaciers, or disintegrated by frost. These stones or portions of rock accumulate by the side of ice

washed sand for making the concrete. At the lowest part of each compartment, I inserted the upper third of a champagne bottle to act as a valve, which could be securely corked during the summer. The bottle may be cut easily by heating it in a gas flame at the part where it is to be severed, keeping the bottle rotating the whole time. When very hot, plunge the bottle into a bucket of cold water up to the desired place, and it will part in two as cleanly as if cut with a diamond.

On the top of the concrete walls I cemented

pieces of rock, which gave a finished appearance to the moraine. Small spaces were left between these pieces of rock, so that, when the upper compartment was full of water, it could overflow into the lower one. The water level of the compartment was 6 inches or 8 inches from the top of the wall. The bottom of the moraine was filled with rough rubble and pieces of stone to the depth of 4 inches. This acted as drainage, affording a free channel at the bottom for the water to reach the valves. Smaller pieces of stone were filled in the spaces between the larger ones, to prevent the stony "soil" from above sifting down and choking the valves. The compartments were then filled with small, stony grit and fairly hard brick rubble that had been passed through a $\frac{1}{2}$ inch mesh sieve. These siftings were put through a very fine sieve to get rid of any dust. This is important, since fine, powdery sand would clog the drainage.

On the surface were arranged large pieces of stone, to give a rugged effect and provide stepping stones (see fig. 53). Water was allowed to trickle down the rocky side into the upper compartment, and overflow into the lower one, finally trickling into a bog-garden. *Reginald A. Malby, Essex.*

(To be continued.)

TREES AND SHRUBS.

WILLOW TREES KILLED BY ARMILLARIA MELLEAE.

The fungus, *Armillaria mellea*, is probably the most destructive root parasite of Conifers in this country, but, with the exception of the Birch, it attacks dicotyledonous trees with comparative rarity. It may be of interest therefore to give some details of a recent case in which this fungus proved to be very destructive to Willow trees (*Salix alba*).

Last summer, a Norfolk landowner who grows this species for the production of wood for cricket bats, noticed that a considerable number of Willow trees in the separate woods died rather suddenly. My attention was directed to the matter, and it was ascertained that *Armillaria mellea* was the cause of death of these trees. During October the fructifications of this fungus were present in great abundance in these woods, and from some of these fruit-bodies it was an easy matter to trace back the well-known

FIG. 52.—MORAINE GARDEN: SHOWING THE WATER-TIGHT WALLS AND MATERIALS FOR DRAINAGE.

streams, and vary in size from specimens a few feet across to fragments as small as shingle or grit.

The constant stream of snow water which runs through them washes away all fine particles of soil, leaving it a waste of soaking stone and shingle. It is probable, however, that, during the summer months, vegetable dust gets drifted or blown on to the moraine, and affords the plants nourishment. The moraine is copiously supplied with ice-cold water all through the growing season, but as soon as the temperature becomes so low that the growth of plants ceases, the supply of water is automatically cut off by the freezing of the glacier, and this is usually followed by a fall of snow. The snow may be several feet thick, and forms a protective covering to the plants till spring.

These are the conditions which need to be imitated as closely as possible in making a moraine garden. In my own case, operations were commenced by digging out the soil in one corner of the rock garden (see fig. 52), about half way from the summit, and in full exposure to the sun. Two compartments were excavated, one above the other, and each about 18 inches deep. The floor of the upper was about 3 inches above that of the lower compartment, and both sloped a little towards the front. The compartments were made watertight by forming the floors and walls of concrete, using well-

FIG. 53.—MORAINE GARDEN WHEN COMPLETED.

subterranean strands of the fungus to the roots of the affected trees. *Armillaria mellea* usually develops a parasitic manner of growth after having lived some time previously as a saprophyte; in these particular woods it had doubtless commenced its saprophytic existence on the stumps of the trees which remained after the felling of a former year.

It is common knowledge that this fungus enters the tree by the roots, whence the mycelium advances towards the base of the stem. By stripping the bark from the roots or collar of an affected tree one readily recognises the snow-white sheets of mycelium characteristic of the fungus when living parasitically.

In the woods to which reference has been made, Ash trees have been planted amongst the Willows, and so far not a single Ash has been affected by the fungus. It would seem, therefore, to be advisable to replace the dead Willows with Ash trees. The disease is so generally distributed in the woods that the operation of cutting trenches around affected trees in order to prevent the subterranean strands of the fungus from spreading to other trees would probably be of little avail in this case. *F. T. Brooks, Cambridge.*

NURSERY NOTES.

MESSRS. JAMES VEITCH & SONS,
CHELSEA.

A RECENT visit served to show that, whilst many subjects have been removed to the nursery at Feltham, others still thrive well in the old nursery at Chelsea. The Javanese Rhododendrons, as befits a class of plants that may be said to have originated on the spot, seem to be little if at all affected by the London atmosphere, and even in January the following varieties were all in bloom:—*Amabile*, pale flesh colour; *balsaminæformis roseum*, double flowers, pink, suffused with yellow; *Exquisite*, yellow, with a rosy tinge; *Edward VII.*, a grand flower of a rich yellow colour; *Imogene*, buff yellow; and *Ne Plus Ultra*, crimson-scarlet. Two delightful hybrids from the dwarf, compact-growing *R. multicolor* are *Ruby*, with rich, ruby-red flowers, and *Mrs. Heal*, pure white. These two varieties are, apart from their compact habit, remarkable for their shallow, thimble-shaped blossoms. From *R. malayanum*, a small but brilliant-flowered species, has been obtained *Little Beauty*, a distinct and richly-coloured form. It is a plant of upright growth, with narrow, somewhat Willow-like leaves, and tiny flowers borne in dense clusters.

Numerous examples of hard-wooded plants were represented in flower, including the following species:—*Erica hyemalis*; *E. gracilis vernalis*, quite distinct from the autumn-flowered form; *E. melanthera*; and *E. ovata*, a slender, bushy species, with roundish, mauve-coloured blossoms. *Daphne indica rubra*; *Acacia Drummondii*, one of the best of the small *Acacias*; *Camellias* of sorts, the varieties being represented by neat, bushy plants, full of blossom; *Grevillea alpina*, a curious, yet pretty, free-flowering Australian shrub; *Eriostemon densiflorum*, laden with its white, starry blossoms; *Correa ventricosa*, and *Veronica formosa (diomsæfolia)*. *Azaleas* were very showy, particularly *Deutsche Perle*, that well-known white variety; *Simon Mardner*, deep-rose, very double; *Madame Hermann Seidel*, white, occasionally striped with red; and *President Oswald de Kerchove*, rose, blotched with carmine, and having a light border.

Amongst what may be regarded as ordinary flowering subjects for this season may be noted *Lilium longiflorum* and *L. speciosum* from retarded bulbs, *Roman Hyacinths*, *Narcissi*, *Lily of the Valley*, *Marguerites*, *Moschosma riparium*, *Euphorbia fulgens*, and *E. (Poinsettia) pulcherrima*.

Less common plants in bloom included *Psychotria (Glouneria) jasminiflora*, a stove shrub,

native of South America, whose clusters of pure white flowers are very suggestive of those of a *Bouvardia*; *Luculia gratissima*, as small plants, each carrying a single head of blossoms; *Aphelandra aurantiaca* *Roezlii*, with terminal heads of vermilion flowers; *Torenia asiatica*, a pretty, trailing plant, whose flowers, violet, blue and white in colour, are freely borne; and *Dalechampia Roezliana*, an Euphorbiaceous plant, with rosy-pink bracts. Lastly, may be mentioned *Acanthus montanus*, a tender member of the Bear's Breech family. It is a native of West Africa, and forms an upright plant, with spiny leaves, the principal veins being of a lighter hue than the rest of the leaf. The flowers, borne in a terminal spike, much resemble those of the hardy kinds. They are white and rose. This species was given a First-class Certificate two years ago by the Royal Horticultural Society.

Gesnera Aurora, which Messrs. Veitch exhibited at the Horticultural Hall on January 3 last, is a delightful, winter-flowering subject. It well repays close inspection, for its charms are so many that they are not revealed at a casual glance. In its handsome, red-marbled, velvety leaves it somewhat suggests *Gesnera zehriana*, next comes the beauty of its flowers, which are of a rich orange colour, heavily suffused on the exterior with vivid scarlet, and dotted inside with bright red. The flowers, too, are not limited to the terminal spike, but they are borne all along the stem, a most notable feature.

Rhododendron Early Gem was seen in a fine group, which had been forced into bloom; the little bushy plants were laden with mauve-coloured blossoms.

Some of the *Laelio-Cattleyas*, *Odontoglossums*, also *Sophranitis grandiflora* and other species, went to make up a goodly show of Orchids, but, as might be expected at the present season, the greatest floral display is afforded by the *Cypripediums*. *W. Truelove.*

THE IMPERIAL DEPARTMENT OF AGRICULTURE IN THE WEST INDIES.

(Continued from page 85.)

A gratifying proof of the value of the work of the Imperial Department of Agriculture is the formation of a series of departments on somewhat similar lines in other portions of the Tropics. The first of these was the important Imperial Department of Agriculture in India. This was followed five years ago by the formation of the Department of Science and Agriculture in British Guiana under the control of Professor Harrison. The other agricultural departments that have been since formed are those in the Federated Malay States, British East Africa, the Gold Coast, Southern Nigeria, and more recently at Jamaica under Mr. Cousins, and at Trinidad under Professor Carmody. A similar Agricultural Department is in course of being formed at Barbados under Mr. Boyell. It is interesting to note that two officers trained in the West Indies (one of them Mr. Maxwell Leffroy) are attached to the Imperial Department of Agriculture in India, two (the Director and Mycologist) attached to the Agricultural Department in the Federated Malay States, one in British East Africa, one in Fiji, and three in the Indian Provincial Departments of Agriculture. It is noticed that in a recent article in the *Standard* it was recommended that the new Agricultural Department in Egypt should also follow "on the lines of the Imperial Department in the West Indies."

It is sometimes remarked that the planters in the West Indies have been slow to try new methods or believe in new introductions. In this they may be only following the attitude of planters in other countries and of our own farmers at home. So far as the West Indies are concerned, the remark has never been generally true, and I am in a position to state that it has become less and less true in recent years. It is a sign of awakening in agricultural matters when the planters at Trinidad and Grenada voluntarily agree to an increase of the export duties on their produce in order to provide larger funds for obtaining scientific advice and assistance and extend agricultural efforts in those Colonies. The

improvement in the methods of cultivation and manufacture of sugar, as already shown, have been largely extended by the planters themselves, as also greater attention has been devoted by them to the introduction of improved varieties of Sugar canes, the more skilful use of artificial manures, and the more effective treatment of diseases. New implements and machinery are being introduced and tested, and the results of the work of the experiment stations are carefully observed and adopted when found of real advantage. There is also, I am happy to say, a more cordial spirit existing between the planters, both large and small, and the scientific workers. It may be the latter are becoming more agricultural and the planters more scientific. In any case, there is hope that by the hearty co-operation of both planters and experts, agriculture in the West Indies will be placed on a sound and progressive basis.

In discussing the progress of agricultural efforts in the Tropics, it is impossible to overlook the valuable services rendered for more than half a century by the Royal Gardens at Kew. Three successive directors of that institution have given their gratuitous services as advisers to the Colonial Office, and the Botanic Gardens at Ceylon, Singapore, Malay States, Mauritius, Jamaica, Trinidad, and British Guiana have been utilised as centres for the distribution of new economic plants sent out from Kew and for the dissemination of information which undoubtedly laid the foundation of much of their present prosperity. Similar work was also done for the Indian Empire. In addition, a systematic investigation of the local floras was undertaken, and we owe the existence of a series of standard botanical works relating to India and the Colonies, as well as the unique collections of Indian and Colonial products and specimens accessible to scientific and commercial men in the museums of the Royal Gardens, Kew has also trained and sent out scores of capable men, who, in their own particular sphere, have rendered valuable services in all parts of the Tropics.

Perhaps the most striking service rendered by Kew was the successful introduction of *Cinchona* (or quinine-yielding) trees from Peru to India and Ceylon. Also the introduction of the Para and other rubber trees from Brazil and Central America to the East. It is these latter which have made it possible to establish the important rubber industries now existing in India, Ceylon, and the Federated Malay States. This is a favourable opportunity of bearing testimony to the splendid services rendered by the greatest of living botanists, Sir Joseph Dalton Hooker, who is still among us, and who follows with deep interest the results of his father's and his own efforts to develop the resources of our Indian and Colonial Empire. It would be impossible to overlook, also, the exceptionally large share taken in similar work by my friend Sir William Threlkeld-Dyer, who for more than 30 years ably maintained the traditions of Kew and ungrudgingly devoted himself to Colonial matters.

THE ROSARY.

BARDOU JOB AND PAUL'S
SINGLE WHITE.

BARDOU JOB is often described as a desirable pillar Rose, but I do not recommend it, as the stems are apt to become bare of shoots, and, in consequence, the plant presents a naked appearance. Paul's Single White is a much better variety as a climber, being more vigorous, with a tendency to make lateral growth. But if the shoots of both sorts are pruned quite close in the manner of the H.F. section vigorous growths will result, and these will continue to flower all through the summer and well into the autumn. The plants are induced to make ample foliage by this treatment, and the leaves enhance the beauty of the flowers.

ROSE PRESIDENT TAFT (SPITFIRE).

This variety is an addition to the hybrid China Roses, and it has many good points. In growth it is vigorous, yet compact, carrying abundant foliage, which in colour resembles the leaves of *Grass an Tepitz*. As a bedding Rose in a mass it should be valuable, as the plant flowers freely. The colour of the blossoms is a bright blood red, whilst the pleasant perfume is not the least valuable attribute of this new variety. *E. M.*

The Week's Work.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

RAISING VINES FROM EYES.—For this method of propagation, the eyes may be started by putting the shoots thickly together in boxes containing leaf-mould, and placing them in a Melon pit or other forcing house. When the shoots have callused over, and roots are beginning to show, an excellent plan is to insert them into square pieces of good turfy loam, about 4 inches square, placing one eye in the centre. If the loam is moist at the time of planting, little water will be required beyond the usual syringings necessary to promote a good growth and keep the young foliage clean. When it is intended to plant the young vines in their permanent quarters in April, I prefer to give them a further shift into a larger turf in preference to planting them in pots, as, by so doing, there is no danger of breaking the roots, and the young plant receives no check. Whilst making their growth, the plants should be exposed fully to the light, and the shoots must be secured to sticks and not allowed to become entangled with one another. When the roots have multiplied in the new soil, occasional waterings with diluted liquid manure will be beneficial, and a sprinkling of a quick-acting patent manure may be also given. The turves must be moved occasionally to prevent the roots from entering any other soil. Those that receive a shift into pots and are intended for pot culture must be watered carefully until the roots have got a good hold of the new compost. Air should be admitted freely, but with discretion, as it is of great importance that the growth shall be strong and vigorous.

EARLY PEACHES.—The disbudding of the growths on early trees should be commenced as soon as possible, and should be done gradually, removing first all those shoots that are badly placed, finally leaving the best shoot at the base of last season's growth, with the leader and an intermediate one when the shoots are of a good length. Nothing is gained by allowing too many growths to remain, and the earlier the surplus shoots are removed the better. When the roots reach a length of 4 or 5 inches, these should be tied in, putting the first tie near to the base of the shoot. Twin-formed or malformed fruits should be removed, but do not thin out the fruits too severely at present, as the thinning may be continued. Syringe the trees at intervals in bright weather, and damp the houses frequently. During severe weather, when extra fire-heat is required, damp the houses last thing at night. Give the borders a good soaking of water if the soil is at all dry, but, before applying the water, lightly fork in a good sprinkling of artificial manure. Keep the borders free from weeds, and remove any suckers that may come from the roots by tracing them down as far as possible to their origin and cutting them off. Ventilate the houses gradually when the temperature commences to rise in the morning, and close them early in the afternoon, taking the fullest advantage of the sun's rays. Make sure that a gentle warmth is circulating in the water pipes before the sun-heat declines.

SUCCESSIONAL PEACH HOUSES.—Houses containing permanent Peach trees for supplying a succession of fruits must be started according to the time ripe fruits are required. The trees should be forced gradually into growth. If the borders show signs of dryness, give a good soaking of clear water before closing the houses. Houses containing trees of late varieties intended for providing a few dishes of fruits very late in the season must be kept as cool as possible. Open the ventilators to their fullest extent whenever possible, and the lights can be removed temporarily; these should not be replaced until the trees show signs of growth. Attend to Peach trees in flower, and, if the weather is bright, open the front ventilators to ensure a free circulation of air. If the weather is cold and dull, continue to pollinate the flowers as recommended for early Peaches. Late trees should receive a slight fumigation before the flowers expand.

STRAWBERRIES.—Continue to introduce fresh batches of plants to ensure a succession later in the season. If shelves are not available for staging the plants, they may be placed in warm pits near to the glass. Plants in flower should be afforded a position where a free circulation of air can reach them. The earliest batches of Strawberries that are swelling their fruits should be placed in a warm house, where a night temperature of from 60° to 65° may be maintained. The plants will require plenty of water and food. Keep the pots and the foliage well moistened by syringing with tepid water. Mildew frequently attacks the plants, especially those of the earliest batches; if any sign of mildew is detected dust the affected parts with flowers of sulphur. Plants that have set fruits imperfectly or are in any way inferior should be discarded at once.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

MEXICAN LÆLIAS.—The Mexican Lælias form a most useful class of Orchids for flowering in winter. *L. autumnalis*, *L. Gouldiana*, and the coloured varieties of *L. anceps*, are compact growing plants that flower freely from Christmas time until the end of January. But even more beautiful than those already named are the white varieties of *L. anceps* that flower during the latter part of January and early in February. The flowers of the white varieties last longer in a fresh condition than those of the coloured forms, and they are most valuable as cut blooms. In some gardens there is a difficulty in getting the plants to flower well, but this is due to imperfect knowledge as to their cultural requirements. A great point to observe is to allow the plants a proper period of rest, which does not mean the withholding of moisture to such an extent as to cause the plants to shrivel, but rather treatment that will cause a natural cessation of growth after the plants have passed out of flower; the longer they are allowed to enjoy this rest the better will they flower in the following season. During this resting period the plants should be placed in a light position in a well-ventilated house, and they should be given just enough moisture to keep the pseudo-bulbs in a plump condition, and the roots, which are active during this stage, in a healthy condition.

AFFORDING FRESH COMPOST.—As already stated the roots of these Lælias are active during the so-called resting period, and it is usual for the plants to produce a cluster of new roots from the latest formed pseudo-bulbs soon after flowering. As soon as these new roots are observed, the plants should be examined, and any that require it afforded some fresh compost. Do not disturb any of the plants unless the condition of the compost necessitates it. In the case of those plants that are not disturbed, it must be seen that the rooting material is not only in a proper condition, but that it is likely to remain so for some considerable time. In cases where repotting is decided upon, shake the old compost from the roots, remove any dead roots, and useless pseudo-bulbs, taking a special care to preserve as many of the healthy roots as possible. If the plants are to be suspended from the rafters, teak-wood baskets will be the best receptacles, but pots and pans may be employed if they are to be grown on the stage. The receptacles should be of a sufficient size to accommodate the specimens for a few years without need of further disturbance. In repotting, place the growths in such a manner that the rhizomes will have a considerable distance to grow before reaching the sides of the baskets or pots. These Orchids do not need a great quantity of rooting material, and the little that is afforded should be of a very porous nature, and plenty of drainage should be provided. The compost may consist of Osmunda fibre two parts, Sphagnum-moss one part, and Polypodium fibre one part. Press the materials firmly about the roots and finish with a surface layer of pure Osmunda fibre. When top-dressing takes the place of repotting some of the old rooting material should be removed, also the dead roots and useless pseudo-bulbs; the drainage material should be examined and put in order, and then a fresh layer of compost added, but do not use too much material. Plants that have been repotted are best accommodated on a stage, where they

may be sprayed overhead during fine weather, until the roots are growing freely in the soil. On no account allow the rooting material to become sodden with moisture, as this would cause the new roots to decay. Another important factor in the successful culture of these plants is cleanliness both from dirt and insect pests. Admit a liberal supply of fresh air whenever the weather is favourable.

THE KITCHEN GARDEN.

By JOHN DENN, Kitchen Garden Foreman, Royal Gardens, Windsor.

ASPARAGUS.—The present is a good time to prick over the surface of Asparagus beds with the point of a digging fork. If any manure from the autumn dressing remains on the surface and is likely to retard the growth of the young shoots, it should be removed, and dug into the alleys, in order to lighten the soil for next season's covering. As digging proceeds, some of the lightest soil procurable from the alley should be spread over the surface of the beds until the crowns are 6 inches under the surface. The beds should then be lined out about 1 foot from the outside row of plants. If new plantations are to be made, the ground should be trenched at once, and a liberal supply of farmyard manure applied. In choosing the ground for new beds, that with a porous sub-soil should be selected if possible; but if the soil is of a heavy, retentive nature, means must be devised to render it more suitable for this crop. In trenching soil of this nature, the bottom should be well broken up to the depth of 4 feet, and a quantity of old rubble or any porous matter mixed with it; rough river sand also may be applied for this purpose. Asparagus will not grow to perfection in soil of a stagnant nature. When the time for planting arrives, a stout stick should be driven into the corner of each bed, and the centre row planted in the middle. The two outside rows may then be planted 1 foot from the edge of the bed, and 18 inches from the centre row. An alley of 3 feet should be allowed between each bed. Planting should not take place before April, and no time should be lost when once the plants have been lifted until they are placed in position and covered with 2 inches of fine soil. There can be no greater mistake made than to allow young Asparagus plants to remain unplanted after receipt from the nursery.

FRENCH BEANS.—French Beans sown in pots a month ago will now be ready for top-dressing. Place a few sticks round the plants to keep them in an upright position, and water them freely with diluted liquid manure, keeping the syringe at work amongst the foliage to prevent red spider. Frequent small sowings in pots should be made, and placed in a temperature of 65°. If heated pits are available, Beans may be planted in rows 18 inches apart, and covered with 2 inches of soil. The soil for this purpose may consist of loam and leaf-mould, and it should be at least 9 inches deep, so that frequent waterings may be unnecessary.

LETTUCES.—The Lettuces raised from seeds sown in October will now be ready for planting on a south border, putting them in rows 1 foot apart, and protecting them from rough winds. If Lettuce seeds were sown early in January, the seedlings will soon be ready to prick into a cold pit, where they should be allowed to remain until ready for cutting in April.

PARSLEY.—Seed may be sown now in boxes and placed in gentle heat for raising plants destined to be grown in some sheltered part of the garden in April. A sowing may be made about the end of the month to afford supplies through the summer. Parsley is a deep-rooting plant, and repays for liberal cultivation. This sowing should be made in an open position, and when the young plants are large enough they should be thinned to 9 inches apart in the rows.

CARROTS.—If seed was sown in pits in December, the seedlings will now be ready for thinning. This should be done before the young plants become drawn, allowing 3 or 4 inches between the plants each way. Give a gentle watering after the crop has been thinned to settle the soil about the roots. Admit air freely when the weather is favourable, and keep the crop well supplied with water.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, K.T., Tyninghame, East Lothian.

THE PLEASURE GROUND.—Any alterations that may be necessary in the lines of paths in the pleasure ground should now be carried out. It is difficult to alter parts of paths unless the alterations are allowed to extend to portions that may seem scarcely to require anything done to them. Therefore, before beginning operations, the lines should be marked clearly by laying a not very thick rope along the parts which it is proposed to alter, and carrying it far enough to join the new to the old without the linking-up being detected. The lawn grass has started to grow, and the lawns should be swept and rolled preparatory to mowing them. It is usual to apply a dressing of lawn sand at this season to lawns infested with Daisies, and in gardens where Daisies are disliked this treatment should be carried out at once. In this establishment, Daisies are destroyed only on the bowling green, and the seedlings are picked out by means of a blunt knife, as are also Hawk-weeds (*Hieracium*) and Plantains (*Plantago*) later in the year. If Stinging Nettles (*Urtica*) are growing anywhere near, they may also be looked for among the shrubs; but they are quite easy to eradicate. The stolons spread only a few inches below the surface, and a workman with a spade which he can pass under the plants and upraise them, will soon cleanse a large area of ground. The Spear Thistle (*Carduus lanceolatus*) also infests shrubberies, and the application of a few drops of sulphuric acid to the centre of each plant is a certain means of destroying them.

DAHLIAS.—In order to obtain a supply of cuttings the old tubers should be introduced into a heated structure. It may not appear necessary to plant the tubers in soil, as they will make plenty of growth if they are merely placed on a bed and kept moistened, but experience teaches that Dahlias, as well as some other plants, form shoots that strike more readily when they have to push their way through soil, leaf-mould, or cocoanut fibre. The old crowns should therefore be covered to a depth of 2 inches with either of these materials, and, as soon as these growths are large enough, they should be severed quite close to the crown. Some good propagators reject the first shoots, selecting only the later ones. Dahlia cuttings form roots readily in an ordinary propagating bed, but they must not be allowed to flag through exposure to bright sunshine.

SALVIA PATENS.—This *Salvia* may be propagated in much the same manner as Dahlias. The tubers may be placed in boxes of leaf soil, and, when the cuttings are formed, they may be dibbled into boxes of light soil, where they will soon form roots.

VERBENA VENOSA.—If the old plants of *V. venosa* have been saved, a stock may easily be raised from the stronger roots. These should be cut into short lengths, each with two "eyes," that are produced opposite to each other; these will give rise to two growths.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

CHERRIES.—The pruning of Morello Cherries growing against north walls should be completed as soon as possible. The pruning and training of this variety differ somewhat from those of sweet Cherries, for the trees bear less frequently on spurs than on the wood of the previous year. The method of pruning and training, therefore, should be carried out on similar lines to that adopted for the Peach and Nectarine, cutting away old or useless branches and retaining the young growths, almost or quite their entire length. All Cherries are impatient of severe pruning, and the less the knife is used the better. Much may be done by summer pinching to keep the spurs and young growths within reasonable bounds, and so restrict the use of the knife, which not infrequently is the direct cause of gum and canker. Orchard or standard Cherries require careful annual pruning, always bearing in mind that varieties differ considerably in habit. Branches inclined in a crosswise direction should be promptly removed or reduced; the rubbing of branches should be avoided at all costs. The pruning of older trees, already trained into the required

shape, consists, principally, in cutting back all side growths to two or three buds from the base, and the shortening of extra strong or long leaders. The buds remaining on the latter will, in their turn, produce side spurs and clusters of fruiting buds during the following season. Trained trees growing upon south or west walls are the most reliable for the production of choice dessert fruit. With careful cultivation, fruit may often be grown equal to that produced under glass. Trees of this description usually blossom profusely, hence the necessity sometimes of carefully thinning or shortening some of the fruit spurs. As standard trees, May Duke, Bigarreau, Knight's Early Black, Bigarreau Napoléon, Noble, and Kentish, are some of the most reliable dessert varieties to grow; whilst Early Rivers, Elton, Frogmore Bigarreau, Bigarreau de Schrecken, Black Eagle, Géant d'Heldeffingen, Black Tartarian, Windsor, and Florence, are all excellent dessert varieties suitable for wall culture.

NUT TREES.—The present is considered by some to be the correct time to prune Nut trees; whilst others favour a much earlier date, at which time there is little or no risk of injury to the flower-buds now in an advanced state; but, by pruning late, the male catkins have had time to serve their purpose, and the infertile branches are more easily discerned. The pruning should consist mainly in keeping the spurs and branches well thinned, cutting back or removing all strong-growing branches, and in clearing away all suckers growing at the base of the stem. Promptly destroy all trees that are in a sickly condition. Trees that receive liberal treatment and a systematic course of pruning, usually bear remunerative crops of fruit. Filbert bushes are often deficient in catkins. It is, therefore, a good plan to plant some tree-blooming varieties amongst the choicer varieties, to act as aids in fertilising the female blossoms. The White, Kentish, Purple and Red-skinned Filberts, and the Kentish and Costard Cobs, are the best varieties to grow to maintain a supply of Nuts throughout the year.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gannerysbury House, Acton, Middlesex.

THE CONSERVATORY.—Camellias are expanding their blossoms, and the plants will need a slightly increased supply of water. Do not, on any account, allow the roots to become dry, and specimens in tubs or pots will need a closer attention in this respect than those planted out. *Luculia gratissima* will soon begin to expand its fragrant blossoms; as a plant for a conservatory border there is scarcely its equal, and it is remarkable that it is not more frequently seen. It should be grown in a well-drained border, in a position not overshadowed by other plants. A mixture of loam and peat, the latter predominating, will suit the *Luculia*, and spring is the best time for planting. *Salvia Heeri*, a slender-growing and rather tall, scarlet-flowering species, is another excellent plant for decorating the conservatory at this season. A few of these plants may be employed as backgrounds to dwarfier subjects, being as suitable for the purpose as forced shrubs. Magnolias flowering in tubs are remarkably showy at this season, as are also Lilacs, Deutzias, varieties of *Prunus*, Wistarias, and other flowering shrubs. Various bulbous plants will now flower quite easily, and there will be no need to hasten them into bloom. Endeavour to secure plants with short, sturdy growths, such as are obtained by the market growers. Summer-flowering plants, such as *Fuchsias* and *Daturas*, in conservatories should receive the necessary pruning and training. Climbers should also be attended to. Look carefully for the presence of insect pests, for this is the season when they can be destroyed most easily. Do not employ high temperatures either by day or night: 45° after nightfall, with a rise to 50° by fire-heat during the day, will be suitable. The blinds will be needed in a few weeks' time, therefore see that they are in proper order.

PALMS.—The various Palms that are grown for decorative purposes may need a thorough overhauling, and the present is much the best season to attend to this work. Kentias, which are the finest Palms for the decoration of dwelling-rooms and corridors, are always in the best

condition when the pots or tubs are well filled with roots; but increased rooting space must be afforded as the plants become larger. Overhaul the stock and, where needed, afford a slightly larger receptacle. In doing this, do not disturb the roots more than is necessary, for if the roots are reduced the plants will need very great care and attention for several months afterwards. Fibrous loam mixed with good peat and some well-broken mortar rubble added, forms a suitable rooting medium for Palms. Take care to pot firmly, and allow a fair space at the surface for watering. Afterwards, if it is possible, keep the plants in a genial growing atmosphere at a temperature of about 55° Fahr. at night, with a slight increase by day. Palms that do not require repotting may be given a top-dressing and an occasional application of a stimulating manure. After several years' experience, I consider Standen's chemical manure the best manure for Palms. It is more powdery than most artificial compounds, and is easily absorbed into the soil, and as readily assimilated by the plants. A pinch given once a week is ample for plants of medium size. After a few applications of the fertiliser, the foliage assumes a darker green colour. Look closely for insect pests, especially scale and red spider.

THE FRENCH GARDEN.

By PAUL AGATIUS.

HOTBEDS.—The mild, dry weather has been favourable for the making of the hotbeds on which cloches will be placed. The beds should be completed within a week or so from this date. Those which were made first have been planted for more than a week, and in each space between the cloches on the south side another Cos Lettuce "Grey of Paris" will be set at once to form the second batch. The plants are placed deeply in the ground, and made firm at the roots. The paths between are kept level with the soil in the beds to prevent the latter being displaced and to facilitate the changing of the cloches. The paths are filled, as often as necessary, with dry, well-broken manure. The Carrots in the frames are well through the soil; they are liable to damp-off, therefore, keep the Lettuces and Radishes in the same frames as the Carrots free from decayed leaves, and allow plenty of light to reach the plants, covering the frames only in case of frost.

FRAMES WITHOUT HOTBEDS.—The Radishes are coming through the ground, and the Lettuces have grown well during the recent fine weather. Where the Lettuce "Little Gem" is grown, ventilation is given moderately and in fine weather only, but where the variety "Passion" has been planted fresh air must be given whenever possible. Most of the cloches are now at liberty; those intended for this branch of the French garden must be placed in position without delay. When cabbage Lettuces and Cos Lettuces are grown under the cloches, a few seeds of Carrot "Chantenay" may be inserted as a catch-crop before placing the cloches in position; should Cauliflowers and Cabbage Lettuces be planted, Radishes or Spinach may be chosen as the intercrop, as the Cauliflowers would require the room before the Carrots are ready for market.

NURSERY BEDS.—The first main sowing of Melons should now be made in a greenhouse, or in a sheltered part of the garden where a hotbed 18 inches thick has been made to accommodate one light. This batch will supply strong plants by April, when the frames and lights from the unheated frames will be at liberty. A few seeds of self-blanching Celery, either Golden Chémou or Pascal, should be inserted on a mild hotbed. This crop must be grown without a check, as the plants are liable to run to seed early in July.

CROPS IN THE OPEN.—The seedling "Passion" Lettuces should now be planted in the open at a distance of 10 inches apart each way, which will give about 2,000 plants for a full-sized bed measuring 65 feet by 11 feet. Spinach or Radish should have been sown previously on the same site as an intercrop. The plants must be set deeply and made firm at the root to withstand the effects of heavy winds and rains. A well-sheltered bed may be sown with Carrot "Chantenay." The seeds should be covered with a good layer of well-decayed manure, in order to promote a quick growth of clean roots.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 20—

Nat. Chrys. Soc. Executive Com. meet.

WEDNESDAY, FEBRUARY 22—

Irish Gard. Assoc. and Benev. Soc. meet.

THURSDAY, FEBRUARY 23—

Women's Agricultural and Horticultural International Union Dinner at Imperial Restaurant, Regent Street.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—39.7°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 15 (6 P.M.): Max. 49°; Min. 40°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, February 16 (10 A.M.): Bar. 30.3; Temp. 49°, Weather—Dull.

PROVINCES.—Wednesday, February 15: Max 55° Ireland S.; Min. 38° Hull.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Herbaceous Plants, Hardy Bulbs, Lilies, &c., at 12; Roses, Fruit Trees, &c., at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—

Hardy Bulbs and Roots, Lilies, Perennials, &c., at 12; Roses, at 1.30; Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

Imported Cattleya Mossie and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.45.

The Royal Horticultural Society.

The 107th annual meeting of the Royal Horticultural Society passed off most satisfactorily. As Sir Trevor Lawrence said in his opening remarks, if there were any Fellows who were dissatisfied with the state of the Society as revealed in the report of the Council for 1910, they must, indeed, be "singularly constituted." The only word of criticism was a complaint from Mr. Elwes that the Society, notwithstanding that it made a profit last year amounting to over £8,000, nevertheless is issuing a journal distinctly inferior to the *Transactions* published by the Society at an early period of its history. Mr. Elwes's remarks were supported by Mr. Engleheart, and the President promised that the subject should receive the careful consideration of the Council.

The meeting was glad to have the assurance of the President that the future custody of the Lindley Library had been made perfectly safe, and a small Committee had been appointed to advise the Council in respect to the purchase of books. He declared that the intention of the Council was to make the Lindley Library the best horticultural library anywhere. For the rest there was not much needling comment. Sir Trevor Lawrence referred to some of the

principal items in the report, and these were almost without exception of a satisfactory nature. His remarks on the Olympia Show seemed to point to the probability that this year the Society's summer show will be of such a character and extent as to excel any similar exhibition which has been held in London during the present generation. The great area covered by the Olympia building will provide an opportunity for arranging the exhibits in a different fashion to that in which they have been seen at the Temple Shows, or even at Holland House, and in this respect, the Olympia Show may foreshadow the greater and more important International Exhibition to be held at Chelsea next year.

In referring to the obituary list, the President made good an omission in the Annual Report by mentioning the name of Dr. Melchior Treub, the great Dutch botanist, who died in October last.

The presentation of the Victoria Medals was a pleasant incident of the meeting, and following the presentation of these medals, Mr. Harry J. Veitch was presented with the Lawrence Medal for a series of highly-meritorious exhibits made by Messrs. James Veitch & Sons during the past year. This is only the third occasion on which the Lawrence Gold Medal has been awarded.

The speech of the Society's treasurer, Mr. Gurney Fowler, was a plain statement of financial progress. He showed that every possible means is being taken to secure the Society against insolvency and to provide for deteriorations. In these respects the present condition of the Society is eminently satisfactory, and there is every reason to congratulate those responsible for its management. As Sir John Evelyn remarked, when proposing a vote of thanks to Sir Trevor Lawrence, there have been eight Presidents of the Society, but never, during any former presidency, has there been such extraordinary developments and prosperity as have been achieved since Sir Trevor Lawrence first presided over the deliberations of the Council.

Sir Trevor has contributed very greatly to this success, and he has been assisted by the present secretary, the Rev. W. Wilks, to whose sagacity and indomitable energy the President paid a very high tribute.

The various committees are usually remembered on such occasions as the annual meeting, and Sir Trevor Lawrence on Tuesday referred to the valuable services they render the Society. Mr. W. Marshall, who has presided at the Floral Committee for twenty-six years, will now have the assistance of Mr. Henry B. May. These gentlemen will act as joint Chairmen of the Committee, Mr. May upstairs, where the novelties are inspected, and Mr. Marshall downstairs, where the groups are judged for awarding the medals. Mr. Marshall's sense of hearing is slightly impaired, and this fact has caused him to seek Mr. May's co-operation.

The Proposed Daffodil Society.

There appears every indication that a sufficient amount of support has been promised towards the formation of a Daffodil society to ensure the realisation of the project, provided that the promoters decide that such a policy is the best that is open to them. In regard to the general question of forming a society, it may be admitted that a live and

corporate body with headquarters in London would be decidedly advantageous to Daffodil cultivators. But there are special circumstances connected with Daffodils which do not apply to any flower—if we except Orchids and Tulips—that at present supports a separate organisation, for none other gives its name to a special committee of the Royal Horticultural Society. In view of this fact, it is scarcely to be wondered at that the meeting on Tuesday last decided not to proceed hastily to establish a fresh society.

It appears that the desire for a separate society arises from a feeling that the Royal Horticultural Society through its Narcissus Committee is not doing all that it might do to satisfy the requirements of Daffodil enthusiasts. Many of these latter think that there is need for a Daffodil "Annual," on something of the lines of the Rose "Annual," and they desire that there shall be one great exhibition of Daffodils in London every spring. These requirements are believed to be impracticable unless a separate society is established, and, if such is really the case, then there is nothing left but for the promoters of the Daffodil Society to press forward the scheme with what energy and support they are able to command. But it is to be hoped that they will first satisfy themselves that there is no alternative course for them to adopt. At one time it was thought by many that the ultimate policy of the Royal Horticultural Society would be directed towards absorbing all the special societies within its fold. This is not likely to happen in the immediate future.

But the present time seems to present a favourable opportunity for the Royal Horticultural Society to prevent the number of special societies being increased. It has plenty of funds and it possesses an influential and representative Narcissus Committee. Why should not the Society empower that committee to hold a Daffodil Show and publish a Daffodil "Annual" every season? The arrangements would be subject to the control of the Council, though emanating from its committee, and the expenditure of the committee in a particular year would also be a matter over which the Council would have perfect supervision. In any case, the Royal Horticultural Society should be given the opportunity of considering proposals of this nature. We do not say that the Council would adopt them, but we believe that it would not lightly disregard reasonable requests. It may be asked why should the Royal Horticultural Society show a preference of this kind to the Daffodil? The answer is that it has already a Daffodil Committee, and, seeing that Daffodil growers are in favour of strengthening that committee, and that plenty of funds are available for the purpose, it would be a logical development of the first intentions of the Council. It may further be asked, if a National Daffodil Society is established, and it includes amongst its principal supporters most of the members of the present Daffodil Committee, what further need will there be for the existence of the committee itself?

In our opinion, the legitimate aspirations of Daffodil growers may easily be met, and the prestige of the Royal Horticultural Society increased, provided that the Daffodil growers are reasonable in their demands and the Council of the Royal Horticultural Society is sufficiently alive to the wishes of the Fellows.

SYMPHORICARPUS OCCIDENTALIS (MOLLIS), FRUITS, WHITE.
FROM SPECIMENS EXHIBITED BY MESSRS. JAMES VEITCH & SONS, LTD.

SUPPLEMENTARY ILLUSTRATION.—A small specimen of *Symphoricarpos occidentalis*, Hooker, was exhibited by Messrs. JAS. VEITCH & SONS on October 11, 1910, at the Royal Horticultural Hall, under the name of *S. mollis*, and it was given an Award of Merit. *S. occidentalis*, the "Wolfberry," bears a considerable resemblance to the common Snowberry (*S. racemosus*), having pure white berries of about the same size. It is, however, a superior plant, for whilst that species has the flowers (and berries) confined to a terminal spike, *S. occidentalis*, as will be seen from our Supplementary Illustration, has the terminal cluster supplemented by axillary ones. The end of the shoot thus becomes a striking panicle of fruits made pendulous by its own weight. *S. occidentalis* is a shrub up to 6 feet high, with oval or oblong leaves, 1 inch to 2 inches long, either entirely glabrous or somewhat downy beneath. The flowers are produced in dense spikes; the corolla is bell-shaped, deeply five-lobed, $\frac{1}{4}$ inch long, pinkish and densely hairy on the inside. The chief botanical distinction between this species and *S. racemosus* is in the relative length of the stamens and style to that of the corolla. In *S. occidentalis* the two former are longer than the corolla; in *S. racemosus* they are shorter. The Wolfberry is a native of the United States from the Rocky Mountains eastwards to Michigan. The species has been in cultivation 70 or 80 years, but, although very ornamental, never seems to have held its own in gardens against the common Snowberry, which appears to have naturalised itself in some districts. The true *S. mollis* is a distinct shrub, being low or even prostrate, the young shoots and leaves always velvety and grey with down; the fruit is white and $\frac{1}{4}$ inch to $\frac{1}{2}$ inch wide. The species only occurs westward of the Rocky Mountains.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting, being the second of the two afternoon meetings arranged for the convenience of country members, will be held in the Lecture Hall of the Institution on the 20th inst., at four o'clock, when a paper will be read by Mr. F. J. LLOYD, entitled "Sugar Beet: Will it Pay to Grow it in Great Britain?"

THE BRITISH ASSOCIATION.—The British Association for the Advancement of Science will be held this year on August 30 and following days at Portsmouth. Professor F. E. WEISS, of the Victoria University, is President of the Botanical Section, and Mr. W. BATESON, Director of the Innes Horticultural Institution, is Chairman of the Agricultural Sub-section.

THE INTERPRETATION OF EXPERIMENTAL RESULTS.—At a time like the present when a considerable amount of experimentation on crops, manures and kindred subjects is being carried on, it is important that those engaged in the work should be in a position to appreciate the sources and extent of probable error in their experiments. We, therefore, draw attention to a valuable paper by Professor Wood and Mr. F. J. M. STRATTON published in the *Journal of Agricultural Science* (vol. iii., part iv., December, 1910), on "The Interpretation of Experimental Results." Among the conclusions reached by the authors, one of the most important is that the probable error of field experiments is about equal to 5 per cent. of the crops. This being the case, it is important for the experimenter to know how many duplicate plots must be employed in order to reduce the probable errors to the extent that may be desired. The authors publish a useful table, which gives information on this head, and point out that more accurate results may be obtained by employing large numbers of small plots than by the use of a smaller number of large plots.

ROYAL AGRICULTURAL SOCIETY.—The Royal Agricultural Society of England will hold its annual show at Norwich from Monday, June 26, to Friday, June 30. The total value of the prizes offered (inclusive of champion prizes, special prizes, and medals) is £10,600, of which sum £2,075 is made up of contributions from the Norwich Local Committee. Prizes amounting to £402 will be given for poultry, including ducks, geese, and turkeys; £28 for butter; £64 for cheeses of 1911 make; £56 for cider and perry; £66 for wool; and £52 for hives, honey, and bee appliances. A horticultural show will be held in connection with the exhibition.

NORTH OF ENGLAND HORTICULTURAL SOCIETY.—We are informed that the council of this Society is already receiving hearty support. It has been decided to hold a monthly meeting and show on every third Wednesday in the month, unless local or other circumstances suggest an alteration of date. These events will take place on the following dates:—March 22, April 19, May 17, June 7, July 19, August 15 (perhaps at Harrogate), September 20, October 18, November 15, and December 20. The council and committees will meet, and a lecture will be given at each meeting. The council is willing to hold a show in co-operation with local societies, and will send deputations to award the Society's diplomas for new plants, fruits, flowers, &c., and award cups if they are invited to do so. The R.H.S. is also willing to send deputations through the northern society and award its medals at representative shows and meetings. It is essential, however, that the North be united and centralised to make this possible. As regards educational work the Society is already receiving the co-operation of the Agricultural and Horticultural Staff of Leeds University. The Scientific Committee, states the Rev. J. BERNARD HALL, promises to be a strong and representative one. A monthly magazine is under consideration.

SCHOOL GARDENS IN LONDON.—At a meeting of the Education Committee of the London County Council on February 8 a discussion took place on the question of "School Gardens." The Day Schools Sub-Committee recommended that the formation of school gardens in connection with public elementary schools maintained by the County Council be approved in principle. In their report on the subject, the sub-committee stated that there were already about 171 of these gardens in, or adjoining, the playgrounds of public elementary schools maintained by the Council, and 60 applications for the formation of gardens had been postponed pending a decision on the general question. The importance of nature study as a subject in the school curriculum was recognised, and in the last few years there had been a steady development of this feature of school life. Although the gardens at many of the schools had been formed for some time, the experiment of utilising them for nature study was a comparatively recent one, as at first they were used for decorative purposes only. The Council's district inspectors were unanimously of opinion that school gardens were of high educational value. The sub-committee were of opinion that it was desirable that gardens should be provided wherever the conditions were favourable. They proposed that a selection should be made from the applications now before them, and that during the next few years about 20 gardens should be formed each year. The average cost of forming a school garden was about £15 each. On the ground that the matter had not been sufficiently considered, and that in many cases the teachers were unable to teach gardening, Mrs. WILTON PRUITS moved that the pro-

posal be referred back to the sub-committee. Miss LAWRENCE, chairman of the sub-committee, said that there had been a prolonged inquiry into the whole subject. It was perfectly true that some of the school gardens at present were not very satisfactory, but they had already had some brilliant successes. Dr. SCOTT LIDGETT declared that they could do much to brighten their poor streets and teach the love of flowers, provided that they worked with skill and enthusiasm and were prepared to incur a very limited outlay of public money. Only three members voted for the amendment.

ROYAL WARRANTS FOR NURSERY AND SEED FIRMS.—In addition to those firms mentioned in the last issue (see p. 90), the Royal Warrant of Appointment to the King has been conferred on Messrs. DICKSON & ROBINSON, Manchester; Mr. T. JANNOCK, Dersingham; W. CUTEUSH & SON, Highgate; and DICKSON, BROWN, & TAIT, Corporation Street, Manchester. Messrs. JOSEPH BENTLEY, LTD., Bafflow-on-Humber, Hull, have received the Royal Warrant as horticultural chemical manufacturers to the King.

WOMEN GARDENERS' SOCIAL GATHERING.—We are asked to announce that the third annual dinner, organised by the Women's Agricultural and Horticultural International Union, of lady farmers and gardeners, will take place at the Imperial Restaurant, Regent Street, on Thursday, February 23, at 7.30 p.m. Tickets may be obtained from the Secretary, Miss ELLA GILL, 64, Lower Sloane Street.

STAFFORDSHIRE SCHOOL GARDENS.—The scheme for school gardening adopted by the Staffordshire County Council in 1904 is proving very successful, no fewer than 170 classes having been held at 146 public elementary schools during the past session. The committee, in issuing in pamphlet form the scheme in general use, attribute a large measure of the success of the school gardens to the County Horticultural Instructors, the late Mr. R. COOK and his successor, Mr. J. STONEY.

SWEET PEA ANNUAL, 1911.—This bright little volume is issued by the National Sweet Pea Society. As a frontispiece to the present number appears a portrait of the President for the year, Lady NORTHCLIFFE. A note on the bibliography of the Sweet Pea, from the pen of Mr. C. HARMAN PAYNE, intended as a supplement to an article in a former volume, shows that more than 20 works on Sweet Peas have been issued since 1907, besides the numerous publications of the Sweet Pea Society. The Rev. JOSEPH JACOB gives an interesting account of the Telenly Sweet Peas, a type that is forced into flower in February. It originated in the garden of the Rev. EDWYN ARKWEIGHT at Telenly, overlooking the town and bay of Algiers. The report of the sub-committee appointed to investigate diseases in Sweet Peas shows that there is still some uncertainty as to the cause of "streak." Many of the specimens sent for examination were found to be attacked by eelworm and by the fungus *Thielavia basicolor*, whilst others showed indications of bacterial disease. The proceedings at the conference are given in detail. The official catalogue of Sweet Pea names has been brought up-to-date by Mr. HORACE J. WRIGHT, whilst the work of the committee, the Society's classification of Sweet Peas, list of too-much-alike varieties, trials and audit of the varieties exhibited are dealt with in separate chapters. Mr. THOMAS STEVENSON gives his experience on lavender-coloured Sweet Peas; Mr. WM. LUMLEY deals with the price of Sweet Pea seeds; and Mr. S. B. DICKS writes on Sweet Peas in British Columbia.

NEW AQUATICS FOR INDOOR CULTIVATION.—

Mr. H. BAUM, in an article on new water plants (*The Gardener*, No. 51, xiv.), describes several new or rare water plants, viz., *Ambulia sessiliflora*, *Ottelia alismoides*, *Aponogeton Dinteri* and *Echinodorus grandiflorus*. *Ambulia sessiliflora*, which is well adapted for cultivation in aquaria, bears more coarsely divided and brighter green leaves than *A. heterophylla*. The flower-bearing shoots rise out of the water and produce white flowers with bright violet flakes and a bluish border. The plant may be propagated by division or from seed. *Ottelia alismoides*, a submerged water plant from the West Indies, resembles in its youth-form a *Sagittaria*, but develops better heart-shaped, enrolled leaves. The plant can only be propagated from seed, which, however, does not germinate well. *Aponogeton Dinteri* was introduced into commerce as *A. flavum*, but when flowered at Dahlem was recognised to be a new species and named *A. Dinteri*, in honour of Mr. DINTER, who discovered and imported the plant from South-west Africa. The plant is rare, owing to the facts that it cannot be increased by division and that its seeds germinate with great difficulty. *Echinodorus grandiflorus*, Michx., is a stately swamp plant, a native of South America; it requires a water temperature of 64° to 77°. When grown in a tank in a suitable house it produces beautiful, large, leathery leaves, and a flower-stalk which bears white male and female flowers. It produces fertile seeds which germinate best in spring.

PUBLICATIONS RECEIVED—*The Selborne Magazine*, edited by G. S. Boulger, F.L.S., F.G.S. (London: George Philip & Son, Ltd.) Price 3d.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE LEO GRINDON HERBARIUM.—The Manchester University has recently, through the generosity of Mr. Grindon, come into possession of the extensive herbarium of the late Mr. Leo Grindon, the well-known botanist and author of *The Manchester Flora*, *Country Rambles*, *British and Garden Botany*, and many other useful and popular books. Mr. Grindon, who died at a ripe old age in 1904, had been lecturer in botany in the Manchester Medical School up to its incorporation with the Owens College, and remained for many years afterwards a capable and enthusiastic teacher of Botany. His herbarium was arranged and used as a teaching collection, and had several characteristic features, which will render it of great service to the botanical department of the University. Instead of confining himself to the formation of a "hortus siccus," Mr. Grindon incorporated in his herbarium many hundreds of plates and thousands of cuttings descriptive of the plants, which he had collected from many botanic gardens or which were sent to him from collectors and correspondents from all parts of the world. Thus the student consulting the Leo Grindon herbarium will find not only dried specimens of the plant he is anxious to see from different parts of the world, but illustrations and diagnoses from standard works of reference, as well as copious plates and references as to their growth in this country, chiefly from the pages of the *Gardeners' Chronicle*. The usefulness of the incorporation of these scientific and horticultural notes in a herbarium is so obvious, that it has been decided by the authorities of the Manchester Museum, in which the herbarium is deposited, to keep Mr. Grindon's collection separate from the general herbarium and to continue to add to it plates and cuttings from the *Gardeners' Chronicle* illustrative of the plants contained in the herbarium. P. E. W.

THE CORONATION FLOWER.—A London daily newspaper is making efforts to boom the Sweet Pea. Not that anyone would think the Sweet Pea required booming: it has already attained

a great hold on gardeners of all classes. But the journal in question, with its characteristic insistence, dogmatically declares that "the Sweet Pea will be known as the Coronation Flower." As is well known, successful journalism has been aptly described as "an intelligent anticipation of events," but in this case the intelligent anticipation seems to be lacking, or perhaps what is more probable, the responsible person has but a very slight knowledge of the appropriateness of any particular flower. The daily repetition of the phrase "it will be known as the Coronation Flower," accompanied by certain cultural directions, tends to make one believe that the writers are not so sure about it after all. It would be interesting to learn on what grounds they claim this distinction for the Sweet Pea. With the majority of growers it will not be in season at the time of the Coronation, for it must be remembered that thousands of persons in the kingdom grow the Sweet Pea almost solely to exhibit it during July and August. If any flower has claims to be called the Coronation Flower it surely must be the Carnation, for not only will it then be in season, but its very name is derived from the word coronation, which, as Professor Henslow showed in *Gard. Chron.*, Dec. 30, 1905, p. 449, was a corruption of "Coronaria." As a buttonhole flower it is far superior to the Sweet Pea. However came the daily newspaper people to overlook the "York Rose" when casting about for a suitable Coronation flower? A. C. Bartlett, *Bookham Grove Gardens*.

DWARF LAURELS.—It is surprising that although dwarf varieties of the common Laurel (*Prunus Laurocerasus*) have existed for a long time, they are finding favour only very slowly. As a hedge plant the variety *schipkensis* is much superior to the common kinds. The leaves are small and of dark colour, whilst the plant is of slow growth. *Zabeliana*, with its narrow glossy leaves and almost horizontal habit of growth, makes an excellent carpet for upright-growing shrubs or trees. It flowers freely, and generally just as well in the autumn as it does in the spring. *Mischeana* and *pygmaea* are two other dwarf varieties, but they lack the special qualities of the others I have mentioned. Z. Smith, *Newry*.

MACHE OR LAMB'S LETTUCE.—Respecting Mr. Bartlett's note on p. 68, I should like to say that, owing to the hardness of Mache, it deserves to be cultivated by those who require salads during the winter. When mixed with Beetroots it makes a salad which is appreciated by many as a winter delicacy. The Italian Mache (*Valeriana ericarpa*) does not run to seed so readily as the common Mache, but it is more susceptible to injury from frost. The seeds may be sown broadcast, but the germination is slow and uncertain in very dry weather unless frequent and light waterings are applied. To obtain good specimens late in December the last sowing ought to be made at about September 15. The seeds will germinate more readily in ground just raked over after a crop than in land freshly dug. As a product for marketing in England Mache cannot be recommended, although I know of special cases where many hundredweights are sold in winter. Paul Aquatics.

NEGLECTED ORCHARDS.—There is need for reform in the fruit orchards of other counties than those named by your correspondents on pp. 33, 76. The principal fault is a lack of pruning. Standard trees that are crowded with superfluous wood should have at least two-thirds of the shoots thinned out, removing those in the inner parts of the tree, and all crossing and inter-crossing branches. G. A. Bramfield.

PSEUDOTSUGA JAPONICA.—Will you allow me to point out an error in regard to the introduction of this Conifer, in the *Kew Bulletin*, and reproduced in your last issue (see p. 90). In 1909 I obtained four plants of *P. japonica* from Bovelli of Pallanza; also six from the Yokohama Nursery Co., all raised from seed. These are thriving here and in other places where they have been distributed by me. I am not aware of the introduction of even "grafted" plants to Great Britain previous to these. H. Clinton Baker, *Bayfordbury*.

Elwes and Henry: *Trees of Great Britain and Ireland*, 813 (1909).

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 14.—The annual meeting of the Fellows is always the occasion of a large exhibition, and it was not surprising to find the Hall well filled with exhibits on Tuesday last. Displays of Orchids were as imposing as ever, the fine plants of white varieties of *Laelia anceps* and specimen of *Cattleya Trianae* var. *Hydra* (see fig. 54) shown by Sir GEORGE HOLFORD being of outstanding merit. The ORCHID COMMITTEE granted one First-class Certificate, three Awards of Merit, and one Botanical Certificate. The exhibits before the FLORAL COMMITTEE embraced showy groups of forced shrubs, Primulas, Carnations, Camellias, Roses, and many exhibits of Alpines. The FLORAL COMMITTEE granted one Award of Merit to a variety of Carnation. The FRUIT AND VEGETABLE COMMITTEE made no award to a novelty, but there were several good groups, including a fine collection of vegetables shown by Mrs. DENISON.

The annual meeting took place in the Lecture Room at 3 o'clock, and the President, Sir Trevor Lawrence, Bart., presided. A report of the proceedings is given on p. 109.

Floral Committee.

Present: Mr. W. Marshall, and Mr. H. B. May (Chairmen); and Messrs. Charles Dixon, W. Bain, W. J. James, W. Cuthbertson, Chas. E. Pearson, Charles E. Shea, A. Turner, H. J. Cuthbush, Jno. Jennings, Jno. Green, R. W. Wallace, W. Howe, J. H. Barr, George Gordon, C. R. Fielder, G. Reuthe, W. J. Bean, Jas. Douglas, C. T. Druery, W. B. Cranfield, E. H. Jenkins, C. J. Lucas, R. C. Reginald Nevill, J. F. McLeod, and R. Hooper Pearson.

Messrs. R. & G. CUTHBERT, Southgate, Middlesex, again showed a large group of forced flowering shrubs, which formed the showiest exhibit in the Hall. There was a wealth of Rhododendrons (*Azaleas*), Lilacs, Wistarias, *Staphylea colchica*, Laburnums, Magnolias, Forsythia suspensa, and species of *Prunus*, with Palms, Ferns, Acers, and other foliage subjects for relief. (Silver-gilt Banksian Medal.)

Messrs. SUTTON & SONS, Reading, furnished a large table with Primulas, mostly varieties of *P. sinensis*, the others being forms of *P. obconica*. There were 350 plants, all well-flowered, compact specimens, representing a good selection of varieties. Two excellent blue varieties were seen in Reading Blue and The Czar, the latter being the darker variety. There were also fine strains of salmon, pink, white, crimson, and other varieties. The Duchess variety was represented by some of the Ivy-leaved type, with a similar lengthening in the petals to that seen in the leaves. Amongst varieties of the stellata type was one of the purest white, even the ring usually seen about the eye being absent. On a table opposite the Primulas, the same firm showed Tulips, arranged in batches of colours, the plants being very compact and dwarf. (Silver-gilt Flora Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, again showed a beautiful exhibit of indoor-flowering plants, the various blooms affording a fine display of colours, arranged with excellent taste. There were many species of Primula, including some fine forms of *P. obconica* and *P. kewensis farinosa*, the latter with large, clear-yellow blooms, like a Jasmine. There was also a large assortment of Rhododendrons (*Azaleas*), all the plants being flowered profusely. Other subjects included a batch of *Boronia megastigma*, another of Lily of the Valley, dwarf Lilacs, and varieties of Rhododendrons of the javanico-jasminiflorum type. As a separate group, Messrs. VEITCH showed a number of standard plants of Rhododendron (*Azalea*) indicum. (Silver-gilt Banksian Medal.)

Messrs. W. CUTHBUSH & SONS, Highgate, London, staged a large exhibit, comprising Carnations, Alpines, forced shrubs, and flowering and fine foliage greenhouse plants. The Carnations provided a showy bank of colour, such beautiful sorts as Pink Delight, Mrs. Fortescue (rose), Mrs. C. W. Ward (rose pink), White Enchantress, O. P. Bassett (scarlet), and Lady Elphinstone (pink) being shown in large bouquets of fine blooms. Amongst the Alpines were splendid spikes of

Iris reticulata and I. Sind-Pers. Other good things noticed were Magnolias, *M. amabilis* and *M. conspicua* being especially finely flowered; *Rhododendron Xmas* Cheer, a floriferous variety; *Boronia megastigma*; *Paphie indica rubra*; and *Dracena Bruantii* variegata, a handsome, greenhouse, foliage plant. (Silver-gilt Flora Medal.)

Messrs. STUART LOW & CO., Bush Hill Park, Enfield, staged a batch of well-flowered Cyclamens, including their fine Salmon King variety. This firm also showed Carnations, making a very pretty exhibit with vases, epergnes, and bowls of these flowers.

Messrs. W. PAUL & SON, Waltham Cross, Hertfordshire, showed pot trees and cut blooms of Camellias. At the back were large specimens of the old *alba plena* variety, still one of the finest of white sorts. *Fimbriata* is also a choice white variety, the petals being lightly fimbriated. Other good ones were *alba simplex* (single), *Donckelaarii* (crimson), *Marchioness of Exeter* (rosy-cerise), *Montionii vera* (white), *Mathotiana* (a very large, crimson-coloured flower), and *L'Avenir* (rose, striped with white). (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, again filled a large table with *Rhododendron* (*Azalea indicum*), Orange trees in fruit, and *Francisca calycina*, as at the last meeting. In addition were several fine plants of *Anætochilus* and *Bertolonia*, with splendidly-coloured foliage. (Silver Banksian Medal.)

Messrs. R. B. MAY & SONS, The Nurseries, Upper Edmonton, showed an interesting exhibit of epiphytal Ferns, in about 20 species and varieties, represented by the genera *Polypodium*, *Drymoglossum*, *Niphobolus*, *Anapeltis*, *Oleandra*, *Davallia*, *Asplenium*, and *Drynaria*. *Davallia heterophylla* has, as the specific name implies, two forms of leaves, one being entire, the fertile fronds only being pinnate. *Oleandra articulata* sends down long aerial roots from the cord-like rhizomes; the leaves resemble those of the common *Scolopendrium*. An interesting exhibit in this group was a board on which were arranged fronds of *Nephrolepis exaltata* and 15 varieties of this species. The type has a simple, pectinate frond, but in some of its derivatives the leaves had become so divided and sub-divided as to resemble a bunch of moss. (Silver Flora Medal.)

Mr. H. BURNETT, Forest Road, Guernsey, again exhibited a display of perpetual blooming Carnations, having the flowers finer than ever. The beautiful pink variety *R. F. Felton* was seen in magnificent blooms, whilst others specially fine were *Niagara* (white), *Britannia* (scarlet), *Marmion* (red on a white ground), *White Enchantress*, *Mrs. C. P. Raphael* (cherry-red), and *Dorothy Gordon* (cerise). (Silver-gilt Banksian Medal.)

Mr. C. ENGELMANN, Saffron Walden, Essex, made a pretty display with Carnations, having a large assortment of perpetual-blooming varieties, including *Carola* (maroon), *Enchantress* (pink), *Harlequin* (yellow, heavily marked with red), *Rose Doré* (reddish, with orange tint), *Britannia* (scarlet), *Regina* (salmon pink), and *Sarah Hill* (white). (Silver Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, again showed varieties of Zonal-leaved Pelargoniums and Cinerarias. Of the former, we may mention, as being especially good, *Mars* (crimson), *Clevedon* (orange), *Hibernia* (red), *King Victor* (cerise-red), *Venus* (white), *Jupiter* (scarlet), and *Lady Curzon* (pink). (Silver Banksian Medal.)

Mr. HERBERT CHAPMAN, Rye, Sussex, showed a number of seedlings of Cyclamen ibericum and varieties of *Freesia*. Of the latter, *Flambeau*, with pale-yellow upper and deeper-coloured lower segments, with an orange blotch on the anterior one, and *Virginalis*, white, with a yellow blotch, were the more noteworthy.

Messrs. W. WELLS & CO., LTD., Merstham, Surrey, showed a few novelties in Carnations, also *Chrysanthemum Kathleen May*, a single crimson variety with a raised, yellow eye.

Mr. HARRY DIXON, Spencer Park Nursery, Wandsworth Common, showed a double-flowered form of *Primula obconica*.

Messrs. G. MOUNT & SONS, LTD., Canterbury, exhibited choice blooms of *Rose Richmond*, on long, stiff stalks, making them valuable for decorative purposes. (Silver Banksian Medal.)

Messrs. R. WALLACE & CO., Colchester, showed a number of early-blooming bulbous plants, having a large assortment of *Crocuses*, *Iris reticulata*, *I. Bakeriana*, *Tulipa Kaufmanniana*, *Cyclamen*

ibericum, *C. Coum*, and *Fritillaria imperialis chitralensis*, with *Hepaticas*, *Saxifragas*, *Snowdrops*, *Primulas*, and other species in season. (Bronze Flora Medal.)

Messrs. J. CHEAL & SONS, Crawley, again put up a rock-garden exhibit, formed of large stones, and planted with an assortment of suitable subjects in flower, and a border of dwarf shrubs at the back. (Bronze Flora Medal.)

Mr. G. REUTHE, Keston, Kent, showed interesting and rare Alpines and uncommon shrubs. *Saxifraga kestoniensis* was about to expand its large, white flowers on crimson stalks; *S. Pauline* is a fine yellow-flowered variety; *S. Kyrillii* is also a yellow variety and quite new; *S. porophylla* is a crimson-flowered species. (Bronze Banksian Medal.)

Mr. MAURICE M. PRICHARD, Christchurch, Hampshire, exhibited Alpines extensively. Forms of *Primula denticulata* were shown well, also the rose-tinted *Megasea speciosa*, *Helleborus subpunctatus*, *Morisea hypogaea*, *Soldanella montana*, *Viola gracilis*, and *Irises* of sorts. (Bronze Flora Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, showed bulbous plants in bloom. There were many species of *Crocus*, including *C. Leichtlinii*, with petals of the palest blue colour; bulbous *Irises* were well represented, also hardy *Cyclamen*, *Snowdrops*, *Scillas*, *Adonis amurensis*, and many others.

Messrs. T. S. WARE, LTD., Feltham, showed Alpines set in rock-work, also *Bletia hyacinthina* and several greenhouse species of *Primula*. Amongst the Alpines, *Megasea ciliata* was conspicuous with its large, white, bell-shaped flowers. (Bronze Flora Medal.)

Messrs. JOHN PEED & SONS, Norwood, also showed Alpines in flower, having the plants in pots. At one end of the exhibit was a collection of succulent plants.

The Misses HOPKINS, Mere Gardens, Shepperton on Thames, showed a rock-garden exhibit planted with *Hepaticas*, coloured *Primroses*, *Helleborus niger*, *Petasites japonica*, *Snowdrops*, and other early-blooming subjects.

Messrs. HEATH & SON, Cheltenham, staged a rocky exhibit as a corner group, having a variety of Alpines in bloom, with dwarf conifers and small shrubs as a background.

Mr. H. C. PULHAM, Elsenham, Essex, was also the exhibitor of a small rock-garden exhibit.

Messrs. WHITELEGG & PAGE, Chislehurst, Kent, exhibited a large number of pot-plants in bloom of *Primula malacoides*.

Miss M. WALTERS ANSON, The Studio, 5, Broadway, Streatham, showed very fine paintings of flowers and vegetables.

AWARD OF MERIT.

Carnation "Coronation."—This is an attractive, pink-coloured *Carnation* of the perpetual-flowering type. Shown by Mr. B. BELL, Guernsey.

Orchid Committee.

Present: Mr. J. Gurney Fowler (in the Chair); and Messrs. Harry J. Veitch, Stuart Low, Fred J. Hanbury, Guney Wilson, T. Armstrong, A. McBean, Walter Cobb, J. Charlesworth, J. Cypher, W. H. Hatcher, H. G. Alexander, J. E. Shill, Arthur Dye, W. H. White, H. Ballantine, J. Wilson Potter, W. Bolton, de B. Crawshaw, C. Cookson, J. S. Moss, and Sir Jeremiah Colman.

Lieut.-Col. Sir GEORGE L. BOLFOED, K.C.V.O., Westonsbirt (gr. Mr. H. G. Alexander), received a Silver gilt Lindley Medal for an excellent group of *Laelia anceps*, which included most of the named white varieties. There were about 20 plants, several of them having as many as 36 flowers on each, the total number of spikes being 94 and carrying in all 350 flowers. A magnificent specimen of *Cattleya Trianae* Hydra received a Cultural Commendation (see fig. 54). *C. Dirce* Westonsbirt variety (*Vulcan* × *gigas*) was also shown in good form.

Sir JEREMIAH COLMAN, Bart., V.M.H., Gatton Park (gr. Mr. Collier), exhibited a group of the pretty *Dendrobium* *Lady Colman*, a large-flowered hybrid raised from *D. Artemis* × *D. Findlayum*.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), exhibited a richly-coloured variety of *Cattleya Trianae* named *Goodsonii*, the

petals were flushed with deep rose; *Odontoglossum ardentissimum* G. E. Day, a new variety with distinct markings, and shown for the first time; also *O. ardentissimum* var. *Lamas*, were noticed in this group.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed *Cypripedium Wellesleyae*, a pretty, light-coloured flower; *C. Little Gem* Westfield var., and a pleasing variety of *Cattleya Trianae*.

The Duke of MARLBOROUGH, Blenheim Palace (gr. Mr. Hunter), exhibited a dark-spotted form of *Cypripedium bellatulum*.

A fine plant of *Odontoglossum Valeria* (Edwardii × *Vuykstekei*) was shown by DE BARRI CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables). The plant had a spike of 36 flowers, which were of a mauvish-brown colour, the lip being reddish-brown with a light-rose apex. In *O. Verona* (*Adrianae* × *Vuykstekei*) the markings were of a reddish-brown colour. *O. Lambearianum* "Purple Queen" is a promising hybrid of intense purple colour. Mr. CRAWSHAY also showed *O. Vuykstekei* and a variety of *O. amabile*.

R. G. THWAITES, Esq., Chessington, Christchurch Road, Streatham Hill (gr. Mr. Black), showed *Sophro-Cattleya Wellesleyae* (*labiata* × *grandiflora*) and *S.-C. Saxa* (*Trianae* × *grandiflora*).

Messrs. CHARLESWORTH & CO., Haywards Heath, received a Silver-gilt Flora Medal for a fine group, containing in the centre some finely-flowered plants of the beautiful *Phalopsis Schilleriana*. The new *Cypripedium Nerissa* (*Maudiae* × *San Acteus*), a well-formed flower of a pleasing greenish-yellow colour, having a few spots on the dorsal sepal, was included in the group, also several *Brasso-Cattleyas*, a grand selection of *Odontiodas*, the richly-coloured *Sophro-Laela Marathon*, a good variety of *Zygocodax Charlesworthii*, and other interesting plants. The front row consisted of *Dendrochilum glumaceum*, which added a graceful effect to the display.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, received a Silver Flora Medal for a group containing many choice *Cypripediums* and *Laelio-Cattleya* *Wilhelmina* (*labiata* × *elegans*), a hybrid of intense mauve colour; the yellow *L. C. Daffodil* (*Hongheana* × *Mercia*); several *Brasso-Cattleyas*, and other interesting Orchids.

Mr. E. V. Low, Vale Bridge, Haywards Heath, was awarded a Silver Flora Medal for a good group of *Cypripediums*. Amongst varieties especially noticed were *Fulshawense*, *Lord Ivor*, *Olivia*, *Maudia*, and *Beryl* West Point var.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Banksian Medal for a group containing many rare and interesting Orchids, including the striking *Selenipedium caudatum*, a fine mass of *Odontoglossum coronarium brevifolium* with eight spikes; *O. Thompsonianum*, the bright-yellow *Laelio-Cattleya Oriens*, *Vanda Watsonii* with pure white flowers, and the curious *Maxillaria luteo-alba*. A fine variety of *Cattleya Trianae* named *Imperial* was also shown well.

Messrs. STUART LOW & CO., Enfield, obtained a Silver Flora Medal for a group, at the back of which were many good plants of *Dendrobium Wardianum*. Other interesting Orchids were *Cattleya Percivaliana* Little Gem, *Bulbophyllum comosum*, *Angraecum citatum* with several graceful spikes, a large plant of *Pleurothallis Roezlii*, and *Cypripedium Mimos Vomgii*.

Messrs. JAMES CYRER & SONS, Cheltenham, received a Silver Flora Medal for a large group which embraced many species and hybrids. *Cypripedium Beckmannii*, *C. Acteus*, two good plants of *Lycaste Skinneri* *alba*, the pretty *Cirrhopetalum picturatum*, and *Cymbidium eburneum* were the more noteworthy examples.

Messrs. J. & A. A. McBEAN, Cooksbridge, were awarded a Silver Banksian Medal for a neat group, in which were several good varieties of *Odontoglossum crispum*, two excellent forms of *Cattleya Trianae*, and a fine form of *Odontoglossum Lambearianum*, having a cream-coloured ground with reddish-brown markings.

Mr. JENSEN, Lindfield, Haywards Heath, exhibited *Cattleya Schroderae* *ilicina*, a well-shaped flower of a pleasing, pale-lilac tint.

Messrs. HASSALL & CO., Southgate, showed *Cypripedium Carola* (see Awards), *C. Beryl*, *Lycaste Skinneri* (with deep-coloured flowers and a white lip), and an almost white form of *Cattleya Mendelii*.

Messrs. KIEHLING & SONS, Westgate Hill, near Bradford, showed *Cypripedium Amanline*: the percentage is unknown, but it is probably derived from *C. Spicerianum*.

Messrs. THEODORE PAUWELS & Co., Meirelbeke, near Ghent, Belgium, exhibited *Brassica-Cattleya Senateur de Bast* (see Awards), a finely-blotched variety of *Odontoglossum crispum*, and *Cymbidium Pauwelsi*.

Flowers of *Dendrobium chesingtonense* Hanbury's var. were exhibited by FRED J. HANBURY, Esq., Brockhurst, East Grinstead.

AWARDS.

FIRST-CLASS CERTIFICATE.

Brassica-Cattleya Senateur de Bast (B.C. *Diphyana-Mossia* B.C. Mrs. J. Leemann), from Messrs. THEODORE PAUWELS & Co., Meirelbeke, near Ghent.—An extremely beautiful hybrid. The sepals and petals are very broad

with rose. The lip is marked with a large red blotch, the side lobes being spotted.

BOTANICAL CERTIFICATE.

Marillaria leontoglossa, from Sir TREVOR LAWRENCE, Bart., K.C.V.O.—The plant bore five spikes of cream-coloured flowers, which are slightly spotted.

CULTURAL COMMENDATION

to Mr. H. G. Alexander, Orchid grower to Lieut.-Col. ST GEORGE HOLFORD, K.C.V.O., Westonbirt, for a magnificent specimen of *Cattleya Trianae* Hydra, bearing 22 spikes, bearing altogether 96 flowers (see fig. 54).

Fruit and Vegetable Committee.

Present: G. Bunyard, Esq. (in the Chair); and Messrs. A. H. Pearson, J. Cheal, C. G. A. Nix, W. Bates, C. Walter, A. Dean, E. Beckett,

the old Wyken Tiffin. (Silver-gilt Knightian Medal.)

Messrs. T. RIVERS & SONS, Sawbridgeworth, staged a large group of Oranges, Shaddocks, and Lemons in pots, also many gathered fruits of the same. Amongst Oranges, fine varieties were seen in Dom Louise, The Egg, Achilles, Queen, and Navel; whilst Lemons, Shaddocks, and Limes were shown in many varieties. (Silver-gilt Knightian Medal.)

Mrs. DENISON, Little Gaddesden (gr. Mr. A. Gentle), exhibited a specially fine collection of vegetables, including 36 dishes of capital Potatos. Of these, Royalty, First Crop, Advance, Snowdrop, Surprise, Early Puritan, Imperator, and Goldfinder were white, and Exhibition, King of the Russets, King Edward VII., and Invieta, coloured varieties. The exhibit also contained splendid samples of Ailsa Craig and Record Onions, Holborn Marrow and

FIG. 54.—CATTLEYA TRIANA VARIETY HYDRA AS EXHIBITED BY LIEUT.-COL. SIR GEORGE HOLFORD.

(Received R.H.S. Cultural Commendation on Tuesday last.)

and of a pleasing rose colour. The lip is large, deeply fringed, and undulated, the centre being richly coloured with gold and prettily veined.

AWARDS OF MERIT.

Cypripedium Carola (*Thompsonianum magnificum* & *Euryale splendens*), from Messrs. HASSALL & Co., Southgate.—A well-shaped flower, the dorsal sepal being white, flushed with deep rose; the petals are broad, and stained a mahogany tint.

Cypripedium aurum lackense (*Sallieri Hypanis* & *Spicerianum*), from Mr. E. V. LOW, Haywards Heath.—The dorsal sepal is white, marked at the base with light greenish-yellow and slightly spotted. The broad petals are yellowish brown.

Cymbidium Pauwelsi (*Cinque* & *Laurinum concolor*), from Messrs. THEODORE PAUWELS & Co., Meirelbeke, near Ghent.—An interesting hybrid, which carried a single flower, having cream coloured sepals and petals slightly flushed

J. Willard, H. Humphreys, A. R. Allan, A. W. Metcalfe, G. Wythes, G. Kell, O. Thomas, G. Reynolds, W. H. Divers, T. Coomber, J. Harrison, H. S. Rivers, J. Jaques, and J. Vert.

Lord HILLINGTON, Uxbridge (gr. Mr. A. R. Allan), showed fruits of McIndoe's Russet Apple, an Australian variety bearing a close resemblance to Royal Russet.

The Duke of Rutland, Belvoir Castle, Rutlandshire (gr. Mr. W. H. Divers), staged a fine collection of Apples, grown in the open in that unfavourable district. Many of the fruits were of exceptional excellence, whilst all were clean, firm, and well preserved specimens. There were 45 dishes in all. The finest cooking varieties were Belle Pontoise, Stone's Pippin, The Queen, Anne Elizabeth, Lord Derby, Gascoyne's Scarlet Seedling, Bramley's Seedling, Mère de Moutage, and Lane's Pince Albert. Of dessert varieties there were excellent fruits of Ribston Pippin, Cox's Orange Pippin, King of the Pippins, Rosemary Russet, Barnick Beauty, White Paradise, King of Tompkin's County, and

Maltese Parsnips, Scarlet Perfection, Scarlet Horn, and Intermediate Carrots, several long and round Beets, Jersey Lily and Golden Ball Turnips, and other kinds. (Silver-gilt Knightian Medal.)

Messrs. SUTTON & SONS, Reading, put up a very attractive collection of vegetables, all from the open ground, including some 36 dishes or mounds, with a big group of Al Curled Kale in the centre. Notable dishes were Early White and Winter Mammoth Broccoli, Royal Favourite and Musselburgh Leeks, New Year Savoy, Tender and True Parsnips, Scarlet Intermediate Carrots, Six Weeks Turnips, Celoriae, *Stachys tuberifera*, and Sullivan Prize Celery. (Silver Knightian Medal.)

Sir WALTER GILBEY, Elsenham Hall, Essex, exhibited an interesting collection of bottled fruits, jellies, and essences. (Silver Banksian Medal.)

Some fine bottled fruits were also shown by Mr. W. POPPART, JUNR., Twickenham; whilst Mrs. MILLER, Moylan, Marlow, had a collection of bottled jams, jellies, and chutneys.

ANNUAL MEETING.

The President, Sir Trevor Lawrence, presided at the anniversary meeting of the Fellows, which took place at 3 o'clock, in the Lecture Room. There was a good attendance.

After 76 names had been proposed and accepted for Fellowship, the President submitted the Council's annual report, which was published in our last issue (see p. 95). He referred to the loss the Society had sustained in the death of King Edward, and said that much satisfaction was felt that King George and his Consort had consented to become patrons of the Society. Speaking of Wisley Gardens, Sir Trevor Lawrence praised the work of Mr. Chittenden, both as director of the laboratory and editor of the *Journal*. The students, he said, had done extremely well during the past year, and the Society possessed an excellent staff of under-gardeners, for whom a new bothy had been erected. Turning to the shows held during the past year, the President made reference to the exhibition at Holland Park, and regretted that it would be the last held in those beautiful grounds; at least, for the present. The show at Olympia was something of the nature of an experiment, but the Council had every reason to anticipate a magnificent exhibition. The Colonial fruit show was the finest of the series. The position of the Society with regard to the Lindley Library had been regularised, and the books had been placed under the control of the Council, with the sanction of the Charity Commissioners. Referring to the losses by death the Society had sustained during the past year, Sir Trevor Lawrence made special reference to Baron Schröder and Dr. Treub. Speaking of the admirable work of the permanent staff, he referred to a recent article in the *Times* newspaper, on the Royal Horticultural Society, in which the writer referred to "its cordial and tranquil efficiency." If such a condition existed, it was due, said Sir Trevor Lawrence, to their secretary, the Rev. W. Wilks. The President concluded his speech with a tribute to the good work performed by the various Committees.

The Treasurer, Mr. Gurney Fowler, seconded the adoption of the report, and referred to some of the items in the financial statement. He said they had closed the year with a balance of £3,370, which represented a gain of £721 over the balance of 1909. The principal items which showed an increase in revenue were subscriptions, dividends and interests on investments, hall lettings, shows, and meetings. The Holland Park Show proved a financial success, but there was a loss on the Colonial exhibition, which had never yet paid its way. The cost of the *Journal* showed an increase of £452, and Wisley gardens an increased expenditure of £154. There were some special items of expenditure in the accounts which were not yearly payments. These included £1,000 contributed to the funds of the Royal International Exhibition 1912, 100 guineas given to the King Edward Memorial Fund, and £557 14s. 6d. to fund the Schröder pension. If these extraneous items were omitted, it would be found that the Society was £2,383 better off than last year. A new bothy, stable, and Orchid house had been erected at Wisley Gardens; over £500 had been added to the depreciation fund, and £14,845 had been invested or re-invested in various stocks. With regard to the Lindley Library, Mr. Fowler said the Council would endeavour to make it second to none as a horticultural library. The Library Committee was holding fortnightly meetings, and would be glad to receive suggestions from the Fellows in respect to the acquisition of books they thought desirable to purchase.

Mr. H. J. Elwes next spoke as follows:—The Society has now accumulated a large capital, which is increasing at the rate of six thousand pounds or more a year, and it is, I think, the largest and wealthiest horticultural society in the world. We have invited the horticulturists of the world to visit England next year, and, no doubt, we shall be able to show them a greater number of well-grown plants than has ever been brought together before. In various ways the Council has shown that they realise the importance of the Society's work. But, in the matter of our publications, I do not think that we are doing justice to our position, for however useful the present *Journal* may be, I think that, if it is compared with what was published by the Society when it was first founded, there is no

ground for satisfaction. A great deal of the matter printed in the *Journal* shows signs of being hastily written, without serious study of the subject. Some of the papers are quite unworthy of the *Journal* of the greatest horticultural society in the world. I am not blaming anyone. The secretary and editor of this Society have to do their best to gather material without assistance from a publication committee, such as are found necessary to control the publications of the Zoological and Linnean Societies, empowered to reject papers which they do not think up to the standard, and to submit them to specialists if they think that such a course is necessary. I have previously advocated the appointment of such a committee to assist our editor, but, so far, nothing has been done. In many cases we are merely reprinting matter which has already appeared in the horticultural Press; in other cases, the papers are of ephemeral interest. In my own literary work, I very rarely have to refer to, or to quote from, the more recent volumes of the Society's *Journal*; while I have to quote frequently from the older volumes, and from the *Gardeners' Chronicle*. What I should like to suggest is that we should keep the *Journal* for all matter relating to exhibitions, committees, trials, and so forth, and institute a quarto publication, under the title of "Transactions," which might be liberally illustrated, and serve to perpetuate papers of permanent horticultural value. There are members of this Society who have found, as I have found, that, unless they are prepared to publish a work privately, they are obliged to put themselves in the hands of publishers, who naturally look principally at the financial aspect of the work. I am sure that, if it were known that this Society would welcome and do justice to a higher class of horticultural papers, by liberally illustrating them in colour when necessary, such papers would be forthcoming, and they would do as much credit to the Society as to their authors. I do not propose that such quarto "Transactions" should be issued gratis to all Fellows of the Society, but I am confident that, if 10 or even 5 per cent. of the 12,000 members were willing to pay an extra subscription, the additional cost of these "Transactions" would be very trifling.

Take, for instance, the very large number of new, beautiful and interesting plants which have been introduced from China by Mr. Wilson in the last few years. Many of them are as yet unknown to the great majority of horticulturists. Mr. Veitch has illustrated some in his *Horibus Veitchii*, the *Gardeners' Chronicle* has figured others, and the *Botanical Magazine* a few more. Professor Sargent, in America, is no doubt preparing to publish a great many more. A series of these plants properly described and figured might, I am certain, for the next 10 years be a most popular and valuable commencement for our "Transactions." Then take the great and horticulturally important family of Amaryllids, of which, since Herbert's work appeared 60 years ago, no collected account has been published except by Mr. Baker. Mr. Worsley has a mass of descriptions, cultural notes and beautiful drawings from his own plants, waiting for an opportunity of publication. What could be more valuable or more popular than an annual instalment of such a work as he could give us? How many members of the Society would be glad to subscribe for an up-to-date revision of such popular and difficult genera as *Primula* or *Saxifraga*. Are we to leave all such work as this to foreign authors or to the chance of amateurs being found who are sufficiently wealthy and enthusiastic to do this work themselves? Of Orchids I do not speak, because they receive a greater degree of attention than most plants on account of their high commercial value. Of fruits also I do not speak, because I know too little about them, but you have only to look at the papers by Knight and others in the old series of "Transactions" to see that in those days, when the income of the Society was not comparable to what it is now, much money was spent in describing and illustrating them. I am sure that, if the Council makes up its mind to make the most of its opportunities, it will be supported by many fellows of the Society of whom they now hear and see little or nothing.

The Rev. George Engleheart agreed with Mr. Elwes that the *Journal* was the one weak spot in the Society; it was not of such a literary or scientific standard as might be expected from such

an Institution as the Royal Horticultural Society. He agreed that a publication committee was necessary. The last volume of the *Journal* was a good one, but there was plenty of room for improvement. He thoroughly supported Mr. Elwes in his remarks, and hoped that the Council would take notice of the subject.

Sir Trevor Lawrence, in reply, said that the matter would receive the serious consideration of the Council, but he was bound to say that, in his opinion, the *Journal* fulfilled its purpose very ably.

The next business was the election of officers and members of the Council, and there being no opposition to the official list, it was carried.

The only other business of the meeting was the presentation of Victoria Medals of Honour to Messrs. Coomber, Cypher, Fielder and May (see *Gardeners' Chronicle*, vol. xlviii, p. 451), and the "Lawrence" Medal to Mr. Harry J. Veitch.

On the motion of Sir John Llewelyn, a vote of thanks was passed to Sir Trevor Lawrence for presiding.

PROPOSED DAFFODIL SOCIETY.

FEBRUARY 14.—A public meeting was held in the Royal Horticultural Hall on Tuesday last to consider the advisability of forming a society, to be called the National Daffodil Society. There was a moderate attendance; amongst those present we noticed Miss Willmott, Rev. G. H. Engleheart, Rev. Joseph Jacob, and Messrs. W. B. Cranfield, R. Sydenham, H. Smith, C. H. Curtis, P. R. Barr, R. W. Wallace, Chas. E. Shea, E. T. Cook, F. H. Chapman, E. M. Crossfield, H. R. Darlington, H. Thomas, J. Douglas, E. A. Bowles and J. Harrison Dick.

The Rev. Geo. Engleheart was appointed chairman of the meeting, and he called upon Mr. Cranfield to make some remarks.

Mr. Cranfield, at the outset, deprecated any suggestion that the work of the new society should conflict with that done by the Narcissus Committee of the Royal Horticultural Society. He considered there was special work which could be undertaken by a society, but which the Daffodil Committee of the Royal Horticultural Society was unable to do. It was not intended to interfere with the work of local associations, which are doing a good work; but they wanted a society centred in London that would hold a Metropolitan show and publish a journal, such as is done by the National Rose Society. Mr. Cranfield read letters from many who had promised their support.

The Rev. Engleheart said that, whilst in no way opposing the formation of such a society, he recognised that there were difficulties. He said there existed already a well-organised association in the Midland Daffodil Society, which almost fills the place of a National Society. There was also the position of the Daffodil Committee of the R.H.S. to consider. But there appeared to be a desire for a legislative body which would represent the Daffodil rather better than did the R.H.S. Committee. There was also a strong need for a metropolitan show.

Mr. Cranfield said he wanted the Royal Horticultural Society to still remain the premier Society. But the end would probably be that the Royal Horticultural Society's Committee would go and the National Society take its place. After Mr. Robert Sydenham had spoken, the Rev. Joseph Jacob brought forward a proposal to ask the Royal Horticultural Society to subsidise its Daffodil Committee, so that it would be enabled to arrange an annual show and pay for the publication of suitable literature, including a Year-Book. If the R.H.S. Council would accept such a proposal, the prestige of the Royal Horticultural Society would be preserved and Daffodil growers would obtain what was wanted.

Mr. Wallace said he considered Mr. Jacob's proposition irrelevant to the business before the meeting. He did not consider the Royal Horticultural Society would entertain such a proposal, and he would support the claims for a National Society.

Mr. Chapman said the Daffodil Committee was of no use, and no great loss would be experienced if it ceased to exist. What was wanted was an annual show to obtain the support of the public.

Mr. Barr supported the scheme for a National Daffodil Society, and said he considered such a body could do the work at present undertaken by the R.H.S. Committee, as well as absorb the Midland Daffodil Society. What was wanted was a

two-days show in London and a Year-Book. He suggested the amalgamation of the Royal Horticultural Society's Committee and the Midland Daffodil Society to form a new body, to be known as the National Daffodil Society.

Mr. C. L. Adams, a member of the Midland Society, strongly deprecated the suggestion of his society losing its individuality. He considered if the Daffodil Committee could be made to meet the needs of the Daffodil world that was all that was needed.

(At this stage Mr. Engleheart was obliged to vacate the chair, and Mr. Barr took over his duties as chairman.)

Mr. Adams proposed that "the meeting be postponed until the Daffodil Committee finds out what the Council of the R.H.S. would be willing to do."

Mr. C. H. Curtis seconded, and Mr. J. Harrison Dick supported the proposition. Several others, including Mr. Bowles and Mr. Darlington spoke, but Mr. Adams's proposition appeared to be in accord with the feeling of the few that remained, and the meeting was therefore adjourned until March 14.

SCOTTISH HORTICULTURAL.

FEBRUARY 7.—The monthly meeting of this association was held in the Goodd Hall, 5, St. Andrew Square, Edinburgh, on this date. The retiring president, Mr. Whytock, occupied the chair, and there was an attendance of 120 members. After the formal business of the meeting was concluded Mr. Whytock introduced his successor in the presidency, Mr. W. H. Massie, who took as the subject of his inaugural address, "Looking Forward or the Future of Our Association." He gave an interesting historical account of the efforts of the association to attain its chief aim, the formation of a horticultural institution in Edinburgh, and he appealed to the members to give their serious consideration to the following proposals which he put before them for their acceptance, namely:—

- (1) To start a fund to provide for a Horticultural Institution, to contain at least a library, and reading room, hall for meetings, and suitable offices, and other accessories.
- (2) To readjust the finances of the Association and of the Chrysanthemum Exhibition.
- (3) To adopt means for the encouragement of the younger members to take a larger share in the work of the Association by providing more facilities for the reading of papers and for discussions amongst themselves, and by offering prizes to those who acquit themselves with most merit, and by instituting examinations and granting to young gardeners certificates of proficiency in theoretical and practical horticulture.
- (4) By instituting a Scottish Benevolent Fund for the behoof of gardeners and others and their widows and children.

On the motion of Mr. McHattie, seconded by Mr. Whytock, and supported by Messrs. Cuthbertson and Todd, Mr. Massie's proposals were remitted to the Council for consideration and report.

Thirty-four new members were elected.

The paper for the monthly meeting on March 7 will be by Mr. Wm. Cuthbertson, J.P., the subject being "A Talk About New Sweet Peas."

BRITISH GARDENERS' ASSOCIATION.
(LONDON BRANCH.)

FEBRUARY 9.—The monthly meeting of the London Branch took place at Carr's Restaurant on this date, when Mr. W. H. North presided. An interesting paper was read by Mr. F. J. Longmire on "Rosaceae." The speaker dealt with the species of the different genera, and gave many interesting facts concerning their history, economic value, and horticultural usefulness.

The chairman announced that the Concert sub-committee had arranged to hold a social evening on Saturday, February 25, commencing at 7.30 p.m., in aid of the Royal Gardeners' Orphan Fund. Mr. Preece and many other artists had kindly offered their services, and everything pointed to the concert being a success. Tickets and programmes, single, 1s., lady and gentleman (double tickets), 1s. 6d. each, may be obtained from the Hon. Sec., Mr. V. Cockram, 37, Bolin Street, Battersea Park, S.W.

ROYAL GARDENERS' ORPHAN FUND.

ANNUAL MEETING AND ELECTION.

FEBRUARY 10.—The 24th annual meeting of the supporters and friends of the Royal Gardeners' Orphan Fund took place on the above date at Simpson's Restaurant, Strand. The Chairman of the Executive Committee, Mr. Henry B. May, presided, and the attendance was equal to the average on these occasions.

The minutes of the last general meeting were read by Mr. Brian Wynne, the secretary, after which the Chairman proposed the adoption of the report and balance-sheet for 1910. These were as follow:—

REPORT OF THE EXECUTIVE COMMITTEE.

In presenting their twenty-second annual report, covering a period of public unrest and excitement which involved the managements of all charitable institutions in great anxiety and concern, the committee are much gratified in being able to congratulate the supporters of the fund on the continued steadiness of its progress and increasing usefulness. With great regret, however, they have to acknowledge that the receipts from annual subscriptions do not show the same amount of expansion as other sources of revenue. The total receipts for the year are satisfactory on the whole, but the committee would be glad indeed to welcome more support in the form of annual contributions, however small, and once more appeal for greater consideration on the part of those for whose children the fund is designed to benefit in their hour of need.

At the commencement of the year there were 117 orphan children receiving the full benefits of the fund, and 18 candidates waiting for election were in receipt of compassionate allowances. Fifteen of them were elected to receive full benefits at the annual meeting, bringing the roll of duly elected beneficiaries up to 132. During the year 28 nominations of candidates were carefully examined and accepted, and from this list 26 have been selected to appeal for election. It is with extreme regret that the committee can only recommend the election of 15 children at the annual meeting, and therefore it has not been considered desirable that the name of more than one child from a family should be placed on the voting list. The total amount disbursed in allowances again exceeded any previous total by some £20, the increase being largely due to the increasing number of candidates appealing for assistance while waiting for election. Since the fund was established the total amount disbursed in allowances made to orphans amounts to no less a sum than over £22,958.

The number of children who have received the benefits conferred by the fund is 203, and it has been a deep source of gratification to the committee to know that one of the earliest girls to be elected on the fund has shown her gratitude for the benefits she received in the past, by becoming an annual subscriber, an example which in due time it is sincerely to be hoped others will follow.

Through the deeply lamented death of his most gracious Majesty, King Edward VII., the annual festival was held at the Hotel Cecil in May, under the shadow of a great national calamity, but the committee rejoice in being able to record the fact that under the able presidency of Sir Jeremiah Colman, Bart., the festival was well attended, and the length of the chairman's list of contributions greatly exceeded their expectations, the total, indeed, exceeding all previous collections. Sir Jeremiah Colman's great love for horti-

culture and the sincerity of his kindly regard for the workers in gardens, was admirably shown on that occasion by his deeply sympathetic appeal for support from those who derive pleasure from their gardens, and by his own munificent donation. The committee are deeply grateful to Sir Jeremiah Colman for all his kindness and encouragement, and they invite the subscribers to share in their gratitude by to-day electing him a vice-president of the fund.

To the stewards on that occasion, through whose kindly efforts the length of the chairman's list was so greatly extended, and to all who so generously assisted in the floral decoration of the Victoria Hall and the adornment of the dinner tables, the committee tender their grateful acknowledgment with the assurance that the results of their labours greatly contributed to the enjoyment of all present.

Arrangements have been made for the next festival to take place at the Hotel Cecil, on Thursday, May 4, and the presidency of one of the earliest supporters of the fund—Nathaniel N. Sherwood, Esq. It will be within the recollection of the earlier supporters of the fund that Mr. Sherwood was one of the first to give the movement, for the establishment of the charity, a helping hand, and gave proof of the sincerity of his desire to set the new institution on a solid foundation, by presiding at the second annual dinner in 1889, and by later undertaking the duties of the responsible office of treasurer. From the first the fund has had no more generous supporter or more ardent friend than Mr. Sherwood, and the committee feel assured that his occupancy of the chair at the Coronation festival will give pleasure to every well-wisher of the fund, and ensure for him their presence and support on that occasion.

The members of the Chislehurst Gardeners' Society, the Scottish Gardeners' Association, the Bradford Chrysanthemum Society, the Leeds Gardeners' Lodge and Panton Societies, the Reading Gardeners' Association, and other gardening bodies are all most cordially thanked for their continued exertions on behalf of the fund, and the committee would most gladly welcome the support of other combinations of horticultural workers who could give valuable help in the same way.

The various honorary local secretaries are also heartily thanked for their much valued assistance. To Mr. George Carver and his horticultural colleagues in the Leeds district, special thanks are due for having organised amongst themselves a system of monthly collections of small sums from gardeners and under-gardeners, and with the happiest results, the fund having benefited considerably by their action.

To Mary, Countess of Echester, Sir Frank Crisp, Mr. Sherwood and his sons, Mr. Leonard Sutton, the Messrs. Rothschild, Mr. E. Rochford, Mr. J. C. Eno, Mr. Anthony Waterer, Mr. H. J. Veitch, Mr. Thomas Smith, Messrs. Parr & Sons, the Messrs. Cuthbert and others who have given most generous support during the year, the committee acknowledge their indebtedness with hearty thanks.

It is again the Committee's regrettable duty to record their sense of the heavy loss which the Fund has sustained by the deaths of old and well-proved supporters whose places it will be most difficult to fill. In Baron Schroder, who bequeathed to the Fund a legacy of five hundred pounds, the horticultural charities in particular, and horticulture in general, have indeed suffered a grievous loss. The name of Mr. William J. Nutting will also be sadly missed by all who knew him, so greatly was he esteemed. In Mr. E. C. Mott and Mr. William Denning, the Fund has also lost friends who always had the welfare of the Fund very near to their hearts.

The members of the Committee who retire by rotation are Mr. William R. Alderson, Mr. George H. Barr, Mr. George H. Cuthbert, Mr. William Howe, Mr. John Lyne,

CASH STATEMENT FOR THE YEAR ENDING DECEMBER 31, 1910.

Obituary.

JAMES WALKER.—It is with deep regret that we record the death, on the 12th inst., of Mr. James Walker, in his 74th year, from pleurisy. Mr. Walker was a conspicuous example of those men who take up a new pursuit comparatively late in life, yet, by diligent study and observation, attain a high rank amongst competent judges and experts. Mr. Walker was born at Rutherglen, one of the oldest burghs in Scotland. In 1875 he relinquished a grocery business, in which he was then engaged, and came to London, determining to devote himself to horticulture. For this purpose, he acquired a market-garden at Whitton, near Hounslow, formerly occupied by Mr. Decimus Clarke. Eight years later, he removed to his present well-known and extensive nurseries at Ham Common. At the commencement, he made a speciality of Cyclamens, and, later, was extremely successful in the cultivation of Peaches and other fruits. He took up the cultivation of Daffodils, and, by assiduous study, aided by a wonderful memory for form and colour, he became one of the foremost of Daffodil experts. Mr. Walker was a member of the R.H.S. Daffodil Committee from its inception, and was a pioneer in Daffodil culture for the market. Since 1885 he has been a member of the R.H.S. Floral Committee, where his peculiar knowledge of most florists' flowers rendered his services invaluable. He was offered the Victoria Medal of Honour, but his characteristic modesty led him to decline this richly-deserved distinction. For some years he served on the Committee of the Royal Gardeners' Orphan Fund, and after his retirement he continued to take a lively interest in the prosperity of this charity. A shrewd, typical Scot-man, he possessed a quaint and kindly humour, coupled with an outspoken candour that caused him to be loved and respected by all who knew him. The funeral took place on Wednesday last at Ham in the presence of a very large number of mourners, amongst whom we noticed many horticulturalists, including Miss Willmott, Mr. Henry B. May, Mr. Poupatt, Mr. J. F. McLeod, and Mr. W. Bates.

ALFRED W. G. WEEKS.—The announcement of the death, on the 9th inst., of Mr. Alfred W. G. Weeks, for many years associated with the old-established firm of John Weeks & Co., horticultural builders, Chelsea, will be received with deep regret. Few men in the horticultural building trade have been better known, or were more deeply respected than Mr. Weeks, who was a man of wide sympathies and great kindness of heart. He was a son of the Mr. Edward Weeks (a member of an old Welsh family) who, at the commencement of the last century, carried on a market-gardening business on the site now occupied by the nursery of Messrs. William Bull & Sons, and the old manufactory of John Weeks & Co., Chelsea. From the market-garden sprang the nursery of Messrs. John Weeks & Co. It was in this nursery, in 1851, that the Victoria regia was flowered in an open-air tank, heated with hot water. The horticultural building business seems to have originated with the patenting of a plant protector by Mr. Edward Weeks in 1818, and to have been greatly developed by Mr. John Weeks, his brother. Mr. Edward Weeks was also the inventor of the kitchen range (afterwards patented by Dr. Kitchener), and subsequently of the system of heating by hot water on what is called the ascending and descending principle which superseded the old flue system, and worked a complete revolution in the mode of heating horticultural and other buildings. Some 40 years ago the firm of John Weeks & Co. consisted of Mr. Alfred Weeks, Mr. George Deal, and Mr. A. O. Saunders, of whom the last-named only now survives. Mr. Alfred Weeks was a lifelong supporter of the Gardeners' Royal Benevolent Institution, and on the death in 1890 of Mr. George Deal, the first chairman of the Royal Gardeners' Orphan Fund, he became a member of the committee, and subsequently a vice-president of that charity. He was also a supporter of a number of other charitable institutions. ☞

mation was conveyed to the committee that the child had expressed a desire to become a gardener, and further that, for certain reasons, it was desirable that he should be removed without delay from the immediate locality. Steps had been taken to provide a place for him in the School of Handicrafts at Chertsey, where he would be taught gardening, but that school would not take him unless a sum of 5s. a week for two years was guaranteed. In these circumstances he, the Chairman, had asked the committee to guarantee that sum, and he now asked the general meeting to approve of the step the committee had taken in this matter. After some remarks by Mr. Alexander Dean, the meeting unanimously approved of the expenditure.

The meeting then proceeded to the re-election of officers and the retiring members of the committee. Mr. Brian Wynne was re-elected secretary. Scrutineers of the ballot were appointed,

THE LATE JAMES WALKER.

and the meeting adjourned till 4.30 p.m. On re-assembling, the Chairman announced that the 15 successful candidates were as follow:—

	Votes.

The unsuccessful candidates were:—Evelyn M. Stokoe, Ralph G. Deadman, William Sprackling, Marjorie E. Billings, Winifred G. Lockyer.

The Chairman stated that there were, in addition to the five unsuccessful candidates, 10 fresh candidates whose claims had already been allowed by the committee, and two candidates whose claims would be considered at an early meeting. These made a list of 15 or 17 candidates already for their election next February. In these circumstances, he need hardly say how important it was that every effort should be made to increase the income of the Fund.

In the evening of the same day, the members of the committee and a few friends dined together at Simpson's, when Mr. Henry B. May again presided.

Mr. William Poupatt, Mr. Thomas A. Sanders and Mr. William P. Thomson, and being eligible, offer themselves for re-election.

The auditors, Mr. M. Rowan and Mr. P. Rudolph Barr, are again most cordially thanked for the great care which they have taken in the examination of the accounts, a duty which yearly becomes more onerous, but always most cheerfully discharged. Mr. Barr is the retiring auditor, and the Committee are glad to have received his consent to be nominated for re-election.

Mr. May said that he thought all present would agree with him when he said that the report and balance-sheet were equally satisfactory. If the Fund had not made phenomenal strides, there had, at the least, been steady and continual progress. Like other institutions of a kindred nature, the committee of the Orphan Fund had found it more difficult last year than usual to collect subscriptions and donations. This difficulty seemed to be felt more acutely towards the end of the year, and certain sums which should have been received in the autumn, were not actually paid until the commencement of January. These facts were shown in the balance-sheet to some extent, but subscribers might bear in mind that any deficiency noticed in this respect had been made good since the turn of the year. He was sorry that the committee felt itself unable to recommend more than 15 candidates for election that day out of the 20 printed in the list. But earnest consideration had to be given to ways and means in respect to the responsibility the fund incurred. He might tell them that they had for the time being gone almost to the extent of their tether. This and similar institutions were governed by rules in regard to their main policies, but he felt that beyond the observance of these rules there was room for the exercise of common-sense on the part of those charged with the responsibility of management. In their own case they had not merely to provide 5s. per week for elected orphans, but there were frequent applications for "grants in aid." Half-a-crown a week was given to accepted candidates whose circumstances made it impossible for them to wait for election before receiving any aid from the fund. Then there were further grants in aid to children about to leave school. For his own part, he considered it would be a most unwise policy to maintain children for several years and to withhold a little extra help from them at a time when it was most essential they should be helped to make a good start in life. He was glad to say that the committee made grants to enable a child to be provided with clothes or with other requisites at the period when they were leaving school for some kind of work. Again, in some cases beneficiaries were found to be in such circumstances at the age of 14 that it was desirable to continue the allowance for another year. This had been done in several cases, and in one at least the allowance had been extended for two years. Last year the committee had distributed in weekly allowances a sum of £1,565 5s. and in grants-in-aid a sum of £145 11s. 8d.; these results were fairly satisfactory. Mr. May then made an appreciative reference to the grant of £20 which had been made by the Société Française d'Horticulture de Londres, and expressed the thanks of the committee and subscribers to that society. He hoped that Mr. Schneider, the president, would soon be restored to his usual health. The motion having been seconded by Mr. Alderson, it was accepted without comment.

The Chairman then rose to make an explanation in respect to a grant which had been made to an orphan who was above the age of 14 at the time of his father's death. It appears that the committee possess the power to continue the allowance, in particular cases, beyond the age of 14 years, but they have not the power to grant a fresh allowance to an orphan who has already attained that age. During last year a particularly sad case had arisen, in which the father died in February at the age of 38 years. His wife was confined on the day previous to her husband's death, and she was buried two days later than her husband. They left seven children; the oldest was just turned 14 years, and the youngest was three days old. The circumstances were so distressing that a local subscription was made to help the children to tide over a short period. Later, some were sent to one institution, and some to another, but the boy of 14 years was found to be too old for any institution, and, unfortunately, he was past the age when a child is eligible for the Royal Gardeners' Orphan Fund. The infor-

LAW NOTE.

AN ORCHID DISPUTE.

BEFORE the Lord Chief Justice and a special jury on the 8th inst., the hearing was concluded of an action in which Mr. Horace Thos. Pitt, of Rosslyn, Stamford Hill, claimed damages for alleged breach of warranty on the sale of a plant against Mr. Henry Whateley, of Spring Gardens, Kentworth, Warwickshire. The defendant denied that the plaintiff was entitled to recover.

Mr. Vachell, K.C., and Mr. Groser appeared for the plaintiff, and Mr. Hugo Young, K.C., and Mr. H. Maddocks represented the defendant. Mr. Vachell, K.C., explained that the plaintiff bought a specimen of *Odontoglossum crispum* from the defendant for 100 guineas in April, 1904, the bargain being made between them at a house of refreshment in Chipping. The defendant said the variety was of the finest blotched type, though he had never himself seen it in flower. In buying it, Mr. Pitt relied upon the custom that he would be able to have his money back if the plant did not turn out as represented. The plant was christened "Hidden Treasure," which was a good name, said counsel, because the treasure had not been discovered yet. The plant was sent by the plaintiff to be looked after by a gentleman in the country. In 1903 the plant came into flower. Mr. Pitt then found it was perfectly worthless from a commercial point of view, the bloom not being of the kind expected. The plaintiff sent the plant back to the defendant and wanted his money returned.

Mr. Pitt gave evidence in support of his case. When the flower appeared it was "perfect rubbish," worth about half-a-crown.

Cross examined by Mr. Hugo Young, the witness said he had given as much as £1,000 for an Orchid. He had bought one parent plant for £300 and sold three bits from it for £3,000.

Between 1904 and 1905 has there not been a slump in Orchids, so that plants which formerly fetched pounds now fetch shillings?—That is true of cheap Orchids, but not of valuable ones. Really good "crispums" have gone up in price.

The witness said he knew the plant was a weakly one when he bought it, and that is why he called it "Hidden Treasure." He denied that he purchased on the authority of a third person who was present at the sale.

Mr. Gods-f, manager to Messrs. Sander & Sons, was shown a picture of the Orchid in dispute, and said it was worth £5.

The defendant, giving evidence in support of his case, said he had not seen the Orchid in question in flower before he sold it. He had previously sold one of the same variety for 700 guineas. Mr. Walters, plaintiff's agent, went with the witness to Birmingham to inspect this plant, which was in bloom. Mr. Walters offered him £105 for the plant in question in this case. The witness said, "You will buy it at your own risk," and he did not say anything as to how it would turn out. Subsequently, the plant was delivered to Mr. Walters. Later, in London, he saw the plaintiff, who said the plant did not look as though it would live. The witness never said that the plant was one of the finest blotched crispums in the world. The Orchid was returned in bloom in 1903. Had the plant in 1904 a bloom like it had in 1910 he would have asked 100 to 150 guineas for it.

Cross-examined, witness said that on an invoice of Orchids everything was described as "fine."

The Lord Chief Justice remarked that everything his gardener supplied to him was always described as fine.

A verdict was returned for the defendant, and judgment was given accordingly, with costs.

GARDENING APPOINTMENTS.

Mr. WM. EDWARDS, for the past 3 years Gardener to Mrs. DE BOEFIELD LARSEN, Hollowood, London, Colchester, and presently Foreman at Stoke Park, Guildford, Surrey, as Gardener to THOS. HENDERSON, Esq., 11, Breckchurch Hall, Colchester, Essex. (Thanks for donation of 2s. for R.G.O.F. box.—F.H.S.)

Mr. F. ARLES, for the past 4 years at Albury Hill Gardens, Woking, as Gardener to E. MATHIAS SMITH, Esq., Godalming, Surrey, near Welwyn, Bedfordshire.

Mr. C. FELL, for the past 5 years Foreman in the plant and fruit department at Hebbury Gardens, Moor Green, Birmingham, as Gardener to CORA COURLESS OF STRAIGHTON, Houghton Hall, King's Lynn. (Thanks for your contribution of 1s. for the R.G.O.F. box.—F.H.S.)

ANSWERS TO CORRESPONDENTS.

ABUTILON VITIFOLIUM: *C. Prentis.* As your tree is in good health and it blooms profusely, it is scarcely likely that the treatment is at fault. The individual flower does not usually last more than two or three days. It is a characteristic of the natural order—Malvaceae—to which it belongs that the flowers should be of short duration. In certain species of Hibiscus, for example, the flower only lasts a single day.

AQUILEGIA: *Amateur.* When the garden area is limited, it is essential that the ground be deeply dug, so as to bring as much new soil as possible under climatic influences. Every other year a good supply of stable or farmyard manure (six barrow loads per square rod) should be well incorporated with the soil at the time of digging during the winter season. In the early spring before the soil is levelled down, sow over the surface the following manurial mixture at the rate of 6 ounces per square yard, 4 parts superphosphate or basic slag, 3 parts bone-meal, and 2 parts kainit. Lightly dig this mixture in before planting. Aquilegias are true perennials not biennials.

BRUSSELS SPROUTS: *D. C. Tambridge Wells.* There is no reason to assume that the seed stocks of your Brussels Sprouts were at fault in the plants failing to produce solid, hard Sprouts. The soil was no doubt too rich, soft and porous. Sow the seeds this season at the end of March, scattering them thinly in shallow drills on ground of medium quality. When the seedlings are 6 inches in height, plant them in ground that has not been manured recently. Lift the plants from the seed-drills with the aid of a fork, preserving intact as many roots as possible. Plant them without unnecessary delay and tread the soil firmly about the roots. The very best of all Brussels Sprouts are produced in market fields, where the soil is made quite hard. Plant in rows at 30 inches apart, and allow the plants a distance of 15 inches in the rows.

CELERY DISEASED: *Hants.* The plants are affected with heart-rot caused by the fungus *Sclerotinia*. The soil is infected, and should be treated with gas-lime.

EARTHWORMS IN POTS: *J. N.* Add three or four handfuls of freshly made quicklime to one gallon of water, and apply the liquid, when clear, to the soil. Worms in potting soil may also be killed by applying a solution of corrosive sublimate at a strength of ½ ounce in 15 gallons of water. Messrs. Cooper, Taber & Co. sell a preparation known as "Chinese Worm Soap," which will cause worms to come to the surface of the soil in pots or in lawns. See that the drainage of the pot is in proper order, as when worms are present in pots the crocks frequently become clogged with fine soil.

ELM TREE DISEASED: *V. H. L.* The tree is attacked by *Nectria ditissima*, the same fungus which causes the "canker" of Apple trees. Diseased branches should be removed. The treatment you have followed is the correct one.

GRUBS IN ASPIDISTRA POTS: *J. G. O.* The plant is infested with the common white spring-tail, *Larva Ambulans*. Soak the soil with lime and soot water at intervals, and sprinkle a little lime on the surface.

HARDY FRUIT: *O. R. J.* The following varieties are amongst the best for training with horizontal branches against a wooden fence. There are eight Pears, four Plums, and three Cherries. The varieties are arranged in their order of ripening, and consist of early, mid-season, and late sorts. *Pears*.—Beurré Giffard, Williams's Bon Chrétien, Marguerite Marillat, Conference, Marie Louise, Doyenné du Comice, Winter Nelis, and Le Lectier. *Plums*.—Bayer's Early Prolific (dessert or cooking) Greengage, Kurke's, and Jefferson (American Gage). *Cherries*.—Bigeurau Schrecken, Governor Wood, and The Noble. In respect to the double cordons, as your fence is low the cordons should be trained obliquely in order to permit of a greater length of stem. The following varieties are suitable for the purpose: *Pears*.—Sonvenir du Couerès, Triomphe de Vienne, Louise Bonne of Jersey, Emile d'Heyst, Doyenné du Comice, (Gou Moreau), Santa Claus, and Marie Benoist. *Plums*.—The Czar, Oulin's Greengage, Coe's Golden Drop, and Late Transparent Gage.

HEATHS: *Rosa.* 1, *Erica gracilis alba*; 2, *E. gracilis*.

MARISCUS OVULARIS VAR. ROBUSTA: *B., M.-R.* This plant belongs to the natural order Cyperaceae. It is a native of the southern United States, where it is said to grow in dry, rocky woods, and in the Pine barrens of New Jersey. The variety *robusta* grows from 2 feet to 3 feet high, and in appearance somewhat resembles our native *Cyperus longus*, but it does not get so tall. It should be planted in a sheltered, shady position in well-drained, loamy soil with plenty of leaf soil added. As the plants come mainly from Texas protection should be given them in severe weather. The species is also known as *Cyperus ovularis*.

MUSHROOM SPAWN: *Correspondent.* To obtain an increase of spawn stable sweepings, with other manures, are mixed with loam and moistened, so that they can be made into "bricks" or cakes. They are then placed to dry. When moderately dry a small piece is cut or scooped out of the centre of each. A small portion of an old cake is inserted into the cavity formed. The cavities of the two cakes are then placed opposite each other, the sides of each two meeting. The cakes when done are placed in one heap, closely packed and fitting together, and either by aid of well-seasoned fermenting material, a flue or otherwise, a dry warmth is maintained throughout this mass, the result being that the spawn permeates the whole. Immediately this is seen the cakes are separated and dried. Thus is maiden spawn held in suspension, as it were, until such time as it is again set to work growing in the prepared beds.

NAMES OF FRUITS: *James Wilson.* Gascoyne's Scarlet Seedling or Glory of England.—*Regular Subscriber.* Reinette Van Mons.

NAMES OF PLANTS: *J. B.* *Garrya elliptica*.—*G. J.* 1, *Juniperus chinensis*; 2, *J. communis*; 3, *Sequoia sempervirens*; 4, *Cephalotaxus drupacea*; 5, *Abies Lowiana*; 6, *A. nobilis*.—*Pat.* 4, *Thuja orientalis*; 5, *Cupressus pisifera squarrosa*; 6, *C. p. var. filifera*.

ORCH SPROUTS WITH SWELLINGS: *Nomad.* The swellings are caused by groups of arrested buds. No disease is present.

PRIMULA OBOVATA AND CATS: *R. C. W.* We have never heard of any animal being poisoned by *Primula obovata*, and it is unlikely that a cat would eat the leaves. When cats have no ready access to a garden they have been known to nibble Ferns in pots in a dwelling room. In the garden they generally prefer to eat the striped grass. The only way to decide if the death of the cat was caused by eating *Primula obovata* leaves would be to examine the contents of the stomach. You will find information on the poisonous properties of *Primula obovata* in an article on "Plants and Skin Irritation" in the issue for August 8, 1908, p. 110.

RICHARDIA (CALLA): *S. P. & Sons.* The crowns are badly infested with a fungus which spreads and passes into the new portions, which should not be used for purposes of propagation.

VIOLETS UNHEALTHY: *J. N.* No disease is present. The decay is due to unsuitable cultural treatment.

YOUNG VINES: *J. S.* The vines should not have been planted until the buds showed signs of bursting in spring. At that time there is a moderate amount of sunshine, and a proper temperature can be maintained without the use of much fire-heat. Since you have already planted them, they should be started into growth, but do not employ too much fire-heat till the shoots and roots are active. Close the house for a week or two, and then apply fire-heat sparingly till the vines are growing freely. Do not cut the rods back now, or the vines will bleed. The better plan is to disbud the rods to the point from which you desire the leading shoot to grow. Should the vines make fairly good progress, in seven or eight years they may be allowed to furnish a trellis of the length you mention.

THE RISE OF SYSTEMATIC BOTANY IN ENGLAND.

THE third lecture of the course of advanced lectures on the History of British Botany was delivered on February 3, at University College, Gower Street, by Dr. Vines, F.R.S., Professor of Botany in the University of Oxford, the subject being "The Rise of Systematic Botany in England," with special reference to Morison and Ray.

The lecturer began by stating that the earliest attempt at a classification of plants that had come down to us was that of Theophrastus of Eresos, who lived B.C. 371-286. It consisted in grouping plants as trees, shrubs, under-shrubs and herbs. This very elementary method remained in force until the time of Linnaeus. No material progress in the science of classification was made during the 2,000 years or so that elapsed between Theophrastus and Morison, though in the works of the later herbalists, such as Boeck, Dodœns and de l'Obel, some attempt at arranging plants otherwise than alphabetically or by their medicinal or economic properties, can be traced. De l'Obel, in particular, succeeded in grouping together most of the plants which now constitute the class Monocotyledons (*Nova Stirpium Adversaria*, 1570).

No definite system of classification was, however, propounded until 1583, when Andrea Cesalpino published his *De Plantis Libri xvi.*, and thereby founded systematic botany. His system was based upon the characters of the fruit, and was, therefore, to some extent artificial; nevertheless, it sufficed to bring together a considerable number of plants into groups which were the antecedents of several of the existing natural orders.

Cesalpino's method was not received with any enthusiasm, and it failed to produce any effect upon the botanical writings of his time. The

need of some method of arranging plants in accordance with their botanical characters seems to have been less and less regarded, as the 17th century came on, and Caspar Bauhin's *Pinar* (1623) may be cited to illustrate the utter lack of any reasonable system at this period.

It was about this time that Morison was born (1620), at Aberdeen. He grew up and studied in his native city, and had begun to teach in the university when the Civil War broke out, in which he took part on the Royalist side, and was severely wounded in 1644. As soon as he was well enough, he fled to France, and pursued there the study of natural science and medicine. Eventually he devoted himself entirely to the study of botany, and was appointed by the Duke of Orleans, in 1650, to take charge of the Royal garden at Blois, a post that he held for 10 years. In 1650, he was presented to King Charles II., who was about to return to England, and immediately after the Restoration the King summoned Morison to London, giving him the title of King's Physician and Professor of Botany with a salary. Morison found time, during the nine years that he spent in London, to write his first work, the *Præudia Botanica*, that appeared in 1669.

In the meantime, by the munificence of Lord Danvers (afterwards Earl of Danby), some progress had been made in the development of botany in the University of Oxford. A physic garden was founded in 1621 (not, as is generally stated, in 1632); but it was not in full operation until about 1640, when it was placed under the charge of Jacob Bobart the elder. At length, in 1669, the state of the funds permitted the appointment of a professor of botany, and Morison was elected the first professor.

Morison, in his *Præudia Botanica*, had called attention to the crying need of a system of classification, and, without actually formulating a system, had made suggestions of importance. He set to work, whilst at Oxford, upon his great *Historia Plantarum Universalis Oronensis*, which was to illustrate his system of classification, and he produced a volume of it (called *Pars Secunda*) in 1680. This volume dealt with only about one-third of the herbaceous plants. Whilst actively continuing his work, Morison was unfortunately run over by a coach in the Strand, in November, 1683, and was so much injured that he died the next day. His unfinished work was entrusted by the university to Jacob Bobart the younger for completion; after many delays, a second and last volume (the *Pars Tertia*), dealing with the remainder of the herbs, was published in 1699. The *Pars Prima*, which was to have treated of trees and shrubs, was never published nor, indeed, written.

Morison died without leaving behind him any complete statement of his system of classification. Such a statement was, however, published in 1720, long after his death, and after Bobart's death, in the form of a small tract, called the *Historia Naturalis Scenographia*, but it is no doubt a very much modified expression of Morison's views. The system is in many respects so similar to that of Cesalpino as to leave no doubt as to the source of Morison's inspiration; nevertheless, as both Tournefort and Linnaeus have testified, Morison's system, although it cannot claim any great originality, yet it accomplished a most useful work in arousing interest in the subject of classification and in reviving the forgotten method of Cesalpino.

Another system of classification was already in the field when Morison began to publish his botanical works, the system of John Ray. Ray was born at Black Notley, Essex, in 1728. He went up to Trinity College, Cambridge, in due course, graduated with distinction, and became Fellow and Lecturer of his College. He was obliged to give up his Fellowship and to leave Cambridge in 1662, on his refusal to sign the declara-

tion against "the Solemn League and Covenant" prescribed by the Act of Uniformity. From that time Ray devoted himself entirely to those studies of natural history in which he had already made considerable progress. His first essay in the department of systematic botany was an article, the *Tables of Plants*, contributed to Dr. John Wilkins's encyclopedic work, *Real Character and a Philosophical Language*, published by the Royal Society in 1669: this is the first systematic work in the English language. The method therein adopted is not of any great value, and called down such severe criticism from Morison that a life-long hostility between him and Ray was the result (see Blair's *Botanick Essays*, 1720). After a few years, Ray produced a more elaborate systematic work, the *Methodus Nova*, 1682. So far as comparison is possible, it does not appear to be very different from Morison's; in fact, it seems clear that Ray, as well as Morison, followed the lead given by Cesalpino a century earlier. Shortly before his death in 1705, Ray issued a new version of his system, the *Methodus Emendata et Lucta*, 1705, which marked a great advance, particularly in the sub-division of flowering plants into Monocotyledons and Dicotyledons. The influence of Ray on the development of systematic botany is to be traced, through Tournefort, to A. L. de Jussieu, who, in 1789, established definitely the Natural System.

Ray was probably more of a naturalist than Morison. The latter wrote nothing on field-botany, whereas Ray produced a *Flora of Cambridge* (1660), as well as a *British Flora* (1670), which was almost the earliest work of the kind, having only been anticipated by William How's *Phytologia Britannica* (1650). Ray's alphabetical catalogue of British plants developed, however, into the first systematic flora, the *Synopsis Methodica Stirpium Britannicarum* (1690).

Thus it is clear that the renaissance of systematic botany was due to the labours of the two distinguished Britons, Morison and Ray; Morison laid the foundation, and Ray built upon it.

The lecture was illustrated with lantern slide portraits of Morison, Ray and the two Bobarts. A printed syllabus, giving a summary of the systems of classification mentioned in the lecture, was distributed.

THE ROMANCE OF A GRASS.

THE *Agricultural Gazette* of New South Wales contains the following interesting history, by Mr. H. C. L. Anderson, of the introduction and spread of the grass *Paspalum ovatum* in the state of New South Wales. In the year 1890 a small packet of grass seed named *Paspalum ovatum* was sent by Baron Von Mueller, Government Botanist of Victoria, to the Department of Agriculture in New South Wales, in the hope that the grass would succeed better under the sub-tropical conditions in this state than it had hitherto done in Victoria, where it had been tried with but partial success for several years.

The packet was divided amongst a number of men who used to experiment with new seeds, and about ½ ounce was sent to Mr. Edwin Seecombe, of Wollongbar, who was the keenest experimenter in the State, and had already done much to introduce new economic plants to the Richmond River district, so little known in those days.

In 1891 Mr. Seecombe, who was the only one that ever took any trouble with this grass, reported that he did not think much of it, as it was rather tussocky, but would continue to propagate it. On May 19, 1892, he sent a specimen of a grass in full seed to be named, and said: "I have only four roots, which are now well rooted. They grow right through our dry summer and keep beautifully green." The grass was identified as

Paspalum dilatatum by Mr. Fred Turner, the Botanist of the Department at that time.

In the following year Mr. Secombe had a small area covered with this grass, which is identical with the *Paspalum ovatum* that Baron Von Mueller had obtained from South America, and which was known under that name in many of the States of North America.

A year afterwards seed was being sold at £1 per lb. To-day there are 190,000 acres of land in this State planted with this grass along the whole of the coast, from the Tweed River to Eden. It is found in such widely different places as Glen Innes, in the New England district, with 30 inches annual rainfall, and at Pera Bore, beyond Bourke, where it grows excellently with 8 inches rainfall, supplemented by artesian water. Its real home, however, is on the coast between the Manning and Tweed Rivers, where it has doubled the productive value of the best land, and has quadrupled the grazing value of inferior land, which 20 years ago was useless for dairying. Mr. Secombe reported in 1890 that there were many farms for sale on the Richmond River at from £2 to £5 per acre, and more sellers than buyers. To-day these farms are eagerly sought by buyers at from £20 to £40 an acre, and many tons of *Paspalum* seed are now yearly exported at 5d. per lb.

Much of this is due to the wonderful properties of *Paspalum dilatatum* as a forage grass, but its very success gives cause for concern now, and the dairy farmers are beginning to realise that this grass alone is not a complete fodder for their milking cows, and that they must either conserve and encourage the white clover or any other leguminous plants which will grow in combination with it, or must cultivate cowpeas and other leguminous plants suitable for the district, to be fed with the *Paspalum*, in order to make a complete ration.

It must be recognised that even the rich North Coast soils cannot continue indefinitely to produce such heavy crops of this prolific grass as they have done in the past without showing signs of exhaustion; but the greatest danger of this grass is its very dense and rank growth, which is apt to choke out the Clover and other subsidiary herbage, and make a single crop for the cows' pasture, which can never be a well-balanced ration for dairy cattle.

It is intended to experiment in the direction of top-dressing *Paspalum* paddocks with bone-dust and other phosphatic manure, both alone and in conjunction with lime and potash manures, to ascertain whether the feeding value of this valuable grass can be maintained and perhaps improved for another generation.

TRACHYMENE CÆRULEA.

This half-hardy annual is a member of the Umbelliferae, a family that is not remarkable for the number of its attractive flowering plants. Growing from 1 foot to 2 feet high, the flower-stems are erect and much branched, each branch terminating in a flat umbel about 2 inches in diameter (see fig. 56). The flowers, which are small and of a pleasing shade of blue, are produced freely during the late summer months. Seeds should be sown in heat in spring, and when the seedlings are large enough they should be pricked off into boxes, and finally transplanted into the border where the plants are intended to flower in April or May. The seedlings are impatient of excessive moisture in the early stages of their growth, and hence require careful treatment in watering. *T. cærulea* is a native of Western Australia, whence it was introduced in the early years of last century, and is the only member of the genus worth growing. There is another species, *T. pilosa*, with small umbels of rather dull flowers, grown in botanic gardens. *T. cærulea* may be sown out-of-doors in April, when the seeds germinate freely, and the plants flower late in the autumn. The plant is also known as *Didiscus cæruleus*. W. I.

THE ROSARY.

CULTURAL NOTES FOR MARCH.

TOWARDS the middle and end of March, the pruning of Roses should be generally undertaken. The Austrian and Scotch Briars, the Penzance Sweet Briars, the Wichuraianas, Macartney, Japanese, and most others of the stronger-growing type need no pruning after the first year from planting, at which time they do best if cut down rather closely. Afterwards it is only necessary to cut out the dead and decaying wood. But the Provence, Damask, and Moss Roses should be pruned rather closely each year. Banksian and other strong climbers trained on

classes need special pruning. A few that should not be cut too closely are (Hybrid Perpetuals) Clio, Dupuy Jamain, Duke of Edinburgh, Hugh Dickson, Magna Charta, John Hopper, Maharajah, Rev. Alan Cheales, and Paul Neyron; (Hybrid Teas) Bardou Job, Augustine Guinoisseau, La France, Grace Darling, Gloire Lyonnaise, Gustave Regis, Gruss an Teplitz, Marguerite Appert, Mme. Pernet Ducher, Papa Gontier, Marquise de Salisbury, and Viscountess Folkestone. The beautiful Lyon Rose needs only the tips of the branches and growths injured by frost cut away. China and dwarf-growing Polyantha Roses also need thinning in the centre, cutting the shoots a little below the old flower trusses. Some few varieties from each section

FIG. 56.—TRACHYMENE CÆRULEA.

walls or trees should have the whole of the sound wood retained; but no shoots that have been injured by frost should be retained.

The more hardy Hybrid Perpetual Roses may be cut back about two-thirds of their length, and should be well thinned in the centre to admit as much light and air as possible. Should extra good flowers be required, much closer pruning must be adopted, and this also applies to the Hybrid Tea varieties. Tea-scented Roses need only thinning where the shoots are crowded, and the remainder cut back about half-way. If specially fine flowers are desired in this section, thin out the young shoots as soon as it can be determined which are the strongest, leaving those that are developing in the best positions.

Some few varieties in all three of these main

being but indifferent growers, need very close pruning. It is a good general rule to prune the weaker growers much harder than those that grow freely. Standard plants need not be pruned quite so closely as would be practised with dwarfs of the same variety.

Pruning should vary a little according to the locality of the garden. From the middle to the end of March is generally suited for the more hardy growers, but the first two weeks of April is better for Tea and other tender varieties. Much will depend upon the season and on whether the plants are growing in a warm or cold district. The dates I have given are suited for gardens in the Midlands during an average season. Pruning should not be hastened simply because the young growth is precocious, as early pruning will cause

the plants to push the dormant buds, and growths thus formed are liable to injury from frost. The first growths that develop at the tips of the shoots assist to keep the more valuable lower eyes in a dormant condition until danger from frost and cold winds is over.

Always cut close down to the last eye or bud, and see that this is so placed that the resulting shoot will grow away from the centre of the plant. By collecting the prunings as soon as possible, and burning them, numbers of insect and fungous pests are destroyed.

After pruning is finished, make good any dead plants, and replace weakly ones from the reserve plants in pots, which I recommended to be grown for the purpose in a former note. Apply a mulch after planting, and dig it in very lightly as soon as the weather permits, preferably after a shower has washed into the soil some of the fertilising properties of the manure. On no account dig the ground deeply; but a slight moving of the top soil will prove an advantage in destroying weeds, and the hoe will work to better advantage throughout the summer.

If Roses trained on walls and fences are unevenly distributed it is advisable to release the shoots and relay them afresh. Bare spaces at the base of the plants can be furnished with dwarfier growing varieties; Tea Roses with a habit similar to Marie Van Houtte, Anna Olivier, and Souvenir de Pierre Notting, are very suitable for the purpose.

ROSES UNDER GLASS.

THE last batch of plants should be started into growth. Care should be taken to destroy insect pests, which are always troublesome during March and April. Feed the more forward plants freely with liquid manure, giving weak but frequent doses. A rise in the temperature of 10 degrees or more during bright sunshine will do no harm, especially towards mid-day. An excessively high temperature may be rendered harmless by sprinkling water among the plants and on the walls or paths, but do not do this so freely as to cause the atmosphere to be so moist at night-time that the house is still damp on the following morning.

Young grafted Roses will need repotting as the plants progress, first warming the pots and the compost to the temperature of the house in which they are growing. This precaution is often neglected, and cold causes a serious check to the roots. Most of the strong growers will need a copious watering with some liquid stimulant, preferably diluted drainings from a cow-stall, or where beasts are being fattened. Let it be given freely, but not too strong. The borders where Roses are planted are frequently dry a little below the surface, and the roots need a considerable amount of moisture at this season. A capital and perfectly safe wash for mildew and insects generally is made from Mo. Effie and Cylin soft soap. Use them together, but at a slightly lower strength than is recommended by the makers. *Practice.*

VEGETABLES.

SELECT VARIETIES OF PEAS.

Owing to the unfavourable summer of 1909 the seeds of culinary Peas ripened badly, and certain varieties in particular germinated unsatisfactorily. The summer of last year proved little, if any, better than the previous one, and much disappointment will probably be experienced with Peas again this season. In looking through the seed catalogues I find that some varieties are omitted from the lists owing to failure of the seed crops. It is well-known that some varieties do better in a wet and unfavourable season than others, and it may be of service to growers to give a list of those which

did best with us last year. Chelsea Gem proved itself worthy of its reputation, and produced a heavy crop of well-filled pods for early supplies. Early Giant, a grand Pea in every respect, proved one of the best and most reliable varieties. Hundredfold, grown here for the first time last year, proved a most useful and profitable Pea. After having furnished an average crop of pods, the fruiting was, to all appearances, finished; but in a short time the plants broke into fresh growth, and flowered, giving a splendid second crop of pods.

Centenary proved to be a thoroughly reliable maincrop variety; while for late supplies, Gladstone and Latest of All proved satisfactory. Another variety which did especially well here was an unnamed sort, which I received for trial from Mr. E. Molyneux, of Swanmore Park Farm. This variety produced a heavy crop of delicious Peas, the flavour being especially good. It is a tall-growing plant, and the pods (though freely produced) are somewhat small. There were no signs of mill dew. *Wilmot H. Yates, Rotherfield Park Gardens, Hants.*

TREES AND SHRUBS.

BAMBOOS AT KEW.

FROM time to time enquiries are received with regard to the species of Bambuseæ in cultivation at Kew; a revised census, based on the Kew *Handlists*, and brought up-to-date, has therefore been printed in the *Kew Bulletin*. This list is as follows:—

- Arundinaria anceps (Mitford).
- " argenteo-striata (Hort.).
- " aristata (Gamble).
- " auricoma (Mitford).
- " chrysantha (Mitford).
- " falcata (Nees).
- " " var. glomerata (Gamble).
- " Falconeri (Mitford).
- " Fortunei (A. & C. Rivière).
- " Hindii (Munro).
- " " var. graminea (Bean).
- " Hookeriana (Munro).
- " humilis (Mitford).
- " intermedia (Munro).
- " japonica (Sieb. & Zucc.).
- " khasiana (Munro).
- " Kokantsik (Kurtz).
- " Kumasasa (Kurtz).
- " macrosperma (Mchcz.).
- " " var. tecta. (A. Gray).
- " nitida (Mitford).
- " pumila (Mitford).
- " pygmaea (Kurtz).
- " racemosa (Munro).
- " Simoni (A. & C. Rivière).
- " " var. Chino (Makino).
- " " variegata (Hook. f.).
- " Veitchii (N. E. Brown).
- Bambusa "Alphonse Karrii" (Hort.).
- " angustifolia (Mitford).
- " arundinacea (Willd.).
- " disticha (Mitford).
- " himalayensis (Hort.).
- " macroculmis (A. Rivière).
- " Nagashima (Marliac).
- " nana (Roxb.).
- " " var. variegata (Hort.).
- " nepalense (Hort.).
- " quadrangularis (Fenzl).
- " tesellata (Munro).
- " vulgaris (Schradi).
- " " var. striata (Lodd.).
- Cephalostachyum flavescens (Kurtz).
- " pergracile (Munro).
- Dendrocalamus giganteus (Munro).
- " latiflorus (Munro).
- " sikkimensis (Gamble).
- " strictus (Nees).
- Gigantochloa atra (Kurtz).
- Melocanna bambusoides (Trin.).
- Olyra floribunda (Raddi).
- Oxytenanthera abyssinica (Munro).
- " albo-ciliata (Munro).
- Phyllostachys aurea (A. & C. Rivière).
- " bambusoides (Sieb. & Zucc.).
- " fastuosa (Hort.).
- " flexuosa (A. & C. Rivière).
- " tulva (Mitford).
- " Henonis (Mitford).
- " mutis (A. & C. Rivière).
- " nigra (Munro).
- " " var. Boryana (Hort.).
- " " " Castillonis (Hort.).
- " " punctata (Bean).
- " puberula (Munro).
- " Quiloi (A. & C. Rivière).
- " " var. Marliacea (Mitford).
- " ruseifolia (Hort. Kew).
- " sulphurea (A. & C. Rivière).
- " violaceus (A. & C. Rivière).
- " vivid-glaucescens (A. & C. Rivière).
- Schizostachyum Zollingeri (Steud.).

NOTICES OF BOOKS.

GARDEN FOES.*

IT seems a pity that the proofs of this work did not pass through the hands of some scientific expert, as then this cheap and admirably got-up book could probably have been unreservedly recommended; as it is, the errors which have escaped correction detract considerably from its usefulness.

To mention a few of the mistakes in the entomological part:—The Apple Tree Mite is stated to do considerable damage, whereas it is innocuous or even beneficial; the larva of the Blue Cabbage Flea (*Haltica*) do not form tunnels in foliage; the hibernation of the viviparous females of the Woolly Aphis is the rule, and not the exception; the statement that the lime and salt wash destroys *ora* is erroneous; the scientific names given for the Celery Fly, Narcissus Fly, Onion Fly, Diamond Black Moth, and others are either wrong or obsolete.

With regard to fungous pests, in the case of many of the diseases, insufficient information is given as to the life-history of the fungus, with the result that a gardener (if relying on this book) would be seriously handicapped in the practical work of dealing with the pest. For instance, no mention is made of the fact that the Apple "scab" or "black spot" fungus attacks the young wood of the Apple—here reliance has evidently been placed on the obsolete leaflet of the Board of Agriculture. Again, in the treatment of the Rose mildew, no mention is made of the "winter-stage" on the shoots. In both these cases, a lack of knowledge on the part of the gardener as to where to look for these fungi in the winter might easily lead to continued ill-success in dealing with the disease. The two scabs of the Potato, viz., *Oospora* and *Sorosporium*, are hopelessly confused; and the erroneous statement first published by the Board of Agriculture that the "Black Scab" of the Potato attacks Mangold and Beet is here repeated. The erroneous identification of the Chrysanthemum "Rust" with *Puccinia Hieracii* is perpetuated also. The conidial stage shown at p. 152 is ascribed to *Plasmopara*, whereas it is that of *Uncinula spiralis*; the illustration at p. 246, purporting to be a "fruiting tuft" of *Septoria*, bears no resemblance to this genus, but is apparently a *Cercospora*. The account of "Finger-and-Toe" is unsatisfactory; for instance, no mention is made of the fact that *Plasmodiophora* is liable to attack common Cruciferous weeds, such as Shepherd's Purse, Charlock, &c.; and the reason adduced for not using sulphate of ammonia on soils liable to this disease is quite wrong. The European Gooseberry-mildew is described as covering the *under* surface of the leaf with a white mould; it is the *upper* surface which is thus attacked. Whilst some of the photographs, e.g., that of "Black Scab" are excellent, others, e.g., that of *Eutypella*, show no recognisable characters of the disease.

The advice given with regard to fungicides is also open to criticism. The only recipe given for the making of Bordeaux mixture—that best of all fungicides—is with "lime water"; it is a serious omission not to mention the well-tried and thoroughly efficacious mixture made with "milk of lime." This latter form of Bordeaux mixture—containing an excess of lime—is invaluable for the gardener for use against Potato "blight" and Apple and Pear "scab." The frequent recommendation to use "Bordeaux emulsion" (a combined insecticide and fungicide) when only a fungicide is needed, as e.g. for Potato "blight," is likely, if followed, to cause gardeners much trouble. The term "dilute Bordeaux mixture" is used without any definition of what is meant by dilution. The formula given for the lime-sulphur spray (if not a

By T. W. Sanders, F.L.S. (London: Collingridge.) 21s pp., Numerous illustrations. 2s. 6d. net.

misprint) is quite out of date. Among insecticides the Paris Green wash (together with Blundell's Paste) should not have been recommended for use; they are often unsafe and are quite superseded by Arsenate of Lead.

The scope of the book is wide; beside the insect and fungus pests of fruit, vegetables, hardy and greenhouse plants, such "foes" as cats, moles, mice, rats, rabbits and hares, lawn and path weeds are well dealt with. There is certainly a mass of very useful information in this book—which, moreover, is well illustrated. *E. S. Salmon.*

GUIDE TO MUSHROOMS.*

MR. WORTHINGTON SMITH'S series of coloured drawings of field and cultivated Mushrooms, which is exhibited in the Botanical Gallery of the Museum of Natural History, South Kensington, has been rendered yet more valuable by the issue of a *Guide*, which contains reproductions of the drawings and descriptions of the varieties figured therein. With this *Guide* in his hand, the student should have no difficulty in determining the several varieties of Agarics, and also in ascertaining whether a given specimen of "Mushroom" is edible or poisonous. Readers of these pages in particular will need no assurance that Mr. Worthington Smith's drawings are wholly admirable and conceived not only in the spirit of an artist, but also in that of a man of science, who has devoted many years to the study of this group of plants.

PRACTICAL AGRICULTURAL CHEMISTRY.†

(A Course for Senior Students.)

TEACHERS of advanced classes in agricultural chemistry will find Professor Wood's syllabus, issued in pamphlet form, of great assistance. The course, which is well planned, is the outcome of 17 years' experience of teaching practical agricultural chemistry. Though designed primarily for use in the Agricultural Laboratory of the University of Cambridge, it will be found invaluable to teachers in similar institutions, and will doubtless, in spite of its high price, find its way generally into their hands.

A JOURNEY TO JAPAN.

(Continued from p. 87.)

THE Buitenzorg botanical gardens are situated on the banks of the River Tjiliwong. Rivulets, streamlets and lakes abound, and in these the Victoria regia, Nelmumbiums, and varieties of *Nymphaea Lotus* grow. Tropical trees, Palms and woody climbers are found in rich collections in the gardens, besides great numbers of Aroids, Bambusas and species of Pandanus. The gardens have existed for 150 years, and during that period have passed through many vicissitudes, at times being nearly demolished. They were founded in 1817 at the suggestion of Reinwardt, and were managed for some years by C. L. Blume, and later, up to 1830, by James Hooper, a Kewite. Teysmann, who followed, was guided by a clear insight, and possessed a keen aptitude for organisation. He was assisted by two clever men, T. K. Haskarl and S. Binnendyk. There are some 10,000 plants in an area of about 150 acres. Binnendyk followed Teysmann in 1869, and later was succeeded by Dr. R. H. C. C. Scheffer, who founded a special garden of more than 180 acres for agricultural and experimental purposes. Dr. Treub, whose recent death was chronicled in these pages, became director in 1880. He enlarged the botanical gardens, the collections and laboratories, also the branch gardens at different localities of Java, especially at Tjibodas and the gardens and instru-

tutions at Buitenzorg. The present chief is Mr. Lovrak.

Buitenzorg makes a special point of the study of trees. The Malayan Islands produce timber trees of high quality, and their straight, up-growing stems are only surpassed in height by North American forest trees, such as Wellingtonia and *Abies Douglasii*, or the Australian Eucalypti. The habits of the tropical giants differ largely from those of trees of more temperate regions. Their leaves are mostly evergreen and of a very firm structure, not exposing their whole surface to the full rays of the sun, but to one side, so that rain and light pass through the trees. The most striking feature are the many trees with broad "buttress" roots, the upper surface of which rises out of the ground and reaches a height of several yards. Sometimes the ground is covered with these thick, board-like, roots twisted in all directions and growing one within the other. The many species of Ficus are especially notice-

time, finally sending down roots to the soil. These young plants grow rapidly, and in time overwhelm the older tree, covering it with roots and branches.

Of fruits, that of *Durio zibethinus* (the Durian) is often praised as being the finest flavoured of any, but it has a very disagreeable smell. Most Europeans never taste it, because they object to the smell. The fruits are heavy, and grow on tall trees.

Nephelium mntabile and *N. lappaceum* are delicious fruits, having a taste much in the way of Grapes. They have a thick skin, something like that of a Horsechestnut and of a beautiful red colour. In the centre is a delicious, pearl-white, roundish, soft fruit, like the inside of a very large Grape. Fruits of *Garcinia Mangostana*, too, are plentiful.

At Buitenzorg, is a fine collection of Palms, which plants grow well in the rich, fibrous loam that is found in most parts of Java. Some, such as *Oreodoxa oleracea* and *O. acumi-*

FIG. 57.—*THLASPI ROTUNDIFOLIUM* GROWING ON A MORaine IN A SWISS VALLEY.

able in this connection, and so also are the tropical species of *Quercus*, *Canarium*, *Shorea*, and many *Stereuleas*. The branches, too, are very often broadened near the stem, forming firm structures capable of resisting every storm. The plant associations are different from those of temperate regions, and it is uncommon to find two trees of the same kind near one another or even in the same neighbourhood. I have mentioned already the trees remarkable for their buttress roots; others have not less remarkable aerial roots, which, when they reach the soil, increase enormously in size, forming new stems, which soon supplant the old ones that pass to decay. They cover, in this way, large areas, and form shelter for many cottages. *Ficus elastica* is planted largely all over this part of the tropics; it forms a gigantic tree, sending out aerial roots from the stem and forming large masses of root and trunk. Seedlings of the same *Ficus* appear on the bark of the trees; they grow as epiphytes for some

nata, have stems nearly 3 feet in diameter close to the ground; others that grow to a large size are *Raplia vinifera*, *Scheelea insignis*, *Elaeis guineensis*, *Attalea spinosa*, *Cocos oleracea*, *C. coronata*, *Borassus flabelliformis*, *Arenga saccharifera*, *Livistona*, and *Sabals* in many species. *Livistona altissima* is a fine, fan-leaved Palm, the fresh green leaves being developed along the stems for several yards. *Acclorhaphie Wrightii* has small, fan-shaped leaves, but the plant forms a large bush of graceful habit 4 to 5 yards high. *Caryota mitis*, *Chrysalidocarpus* and *Phoenix* in many species are represented in these gardens by graceful and large specimens. There is also a remarkable collection of rotans, including species of *Calamus*, *Desmoncus*, and *Dæmonorops*, some with stems several hundred yards long. Very remarkable, too, are such Palms as *Eugeissona triste*, *Oncosperma filamentosum*, *O. horridum*, and *Metroxylon Rumphii*, which has stems of very large size. There are very many other rare, beautiful, and showy

* *Guide to Mr. Worthington Smith's Drawings of Field and Cultivated Mushrooms and Poisons or Worthless Fungi often Mistaken for Mushrooms*, 1910. 1s.

† *A Course of Practical Work in Agricultural Chemistry for Senior Students*, by T. B. Wood, M.A. (Cambridge: The University Press.) 2s. 6d.

Palms. Two large areas of ground are covered with them, each kind being planted in two's or threes, and they grow exceedingly well. Specimens of Pandanus are equally flourishing, their stems sometimes rivalling those of the Palms, whilst all are very graceful. Pandanus graminifolius, the well-known, small, dark-leaved species, covers large areas. P. labyrinthicus develops its branches on thick, stick-like roots; the leaves of P. furcatus are used for making mats and other useful things. But the Bamboos are the most graceful plants. Bambusa arundinacea has most claim to beauty, whilst Dendrocalamus giganteus is the largest. Next to it in size are Gigantochloa verticillata, G. robusta, G. aspera, G. ater, and G. Apus. Detdrocalamus strictus and Bambusa polymorpha form graceful heads, the stems arising very near together, but branching at some distance from the ground. Only the tree Ferns can rival with them in gracefulness. Like the

THE ALPINE GARDEN.

HOW TO BUILD A MORAINE.

(Concluded from p. 100.)

PLANTS FOR A MORAINE GARDEN.

THE following plants will succeed in a moraine: —*Ethionema coridifolium*, *Androsace Laggeri*, *Anemone vernalis*, *A. narcissiflora*, *Campanula Allioni*, *C. alpina*, *C. cenisia*, *C. morettiana*, *C. pulla*, *C. Zoyssii*, *Cyananthus lobatus*, *Dianthus glacialis*, *D. alpinus*, *D. neglectus*, *Draba pyrenaica*, *Eritrichium nanum*, *Gentiana bavarica*, *Geum reptans*, *Gypsophila cerastoides*, *Douglasia vitaliana*, *Houstonia cerulea*, *Linaria alpina*, *Lychnis alpina*, *Papaver alpina*, *Aquilegia alpina* (true), *Primula integrifolia*, *P. glutinosa*, *P. viscosa*, *P. minima*, *Ranunculus glacialis*, *R. alpestris*, *R. parnassifolius*, *Saxifraga aizoides*, *S. oppositifolia* (see fig. 58), *Silene acaulis* and

spread upwards to the stone itself, so that the original patch on the moraine can be removed afterwards.

When autumn approaches the water supply should be reduced, and at about the end of October the corks should be withdrawn from the bottle-necks. These improvised valves may be covered with a flower pot turned bottom upwards and sunk in the soil.

It will be readily seen that rain-water will sink through the stony soil to the bottom of the moraine, and then escape through the bottle-neck into the next compartment, and finally on to the bog. In winter it is necessary to protect the plants from rain, as well as from smoke and dirt during foggy weather, by pieces of glass, each a little larger than the plant, and supported on wires. If these are arranged about 3 inches or 4 inches above the plants, the latter will be kept quite dry.

FIG. 58—*SAXIFRAGA OPPOSITIFOLIA* ON THE MORAINE AT ROSENLAUI, SWITZERLAND.

Pandanus, they form forests, but mostly in mountainous regions, where they grow nearly as high as Palms. The collection of Ferns is interesting, though not large, and there are many climbers, including climbing Aroids. The woody climbers are planted on an island, opposite the Tjiliwong River, where they grow on all sorts of trees. It is very interesting to observe how they grow and fasten themselves to their hosts. There are climbing Bamboos, *Dmochloa Tjankorreh*, the giant *Bauhinias* and *Entadas*. Many, like some of the *Anonaceæ*, have beautiful flowers; others are interesting in the way they cling for support; some, including many species of *Asclepia*, *Dischidia*, and other allied genera which associate with ants and develop roots inside cup-like structures formed by the leaves, are real epiphytes. Nearly 2,000 different Lianes may be found at Buitenzorg. *Fr. Henkel*.

(To be continued.)

varieties), *Thlaspi rotundifolium* (see fig. 57), *Trifolium alpinum*, *Viola biflora*, and *V. calcarata*. This list is not an exhaustive one, as there are other subjects which can be introduced if desired.

Care should be taken when turning the plants out of their pots to dislodge the loose soil without unduly disturbing the roots, and especially to remove any mould that is attached about the neck of the plant. The plants will need watering carefully overhead for the first fortnight or so after planting. Most of them are comparatively slow-growing species; many of them develop fine, thread-like rootlets, which cling to the adjacent stones, forming a matlike growth. The bare spaces between the plants may be carpeted with *Ionopsidium acaule*, and the big stones may be draped with *Arenaria balearica*, which, if planted at the base of the stone, will quickly

It is especially important to afford this protection to plants, such as *Draba androsace* and *Eritrichium*, which have leaves that hold the moisture.

The glasses allow a free current of air to pass over the plants and do not in any way "coddle" them.

It is advisable, once or twice each year, to lightly dust the surface of the moraine with finely-sifted leaf-mould: the merest sprinkling will suffice. The leaf-mould will in time be washed down amongst the stones. In spring, as soon as the plants become active, but not during the first few warm days of February or March, the plugs may be reinserted, and when growth is well advanced, water may be again introduced. The first season in the moraine garden will find strong, healthy plants that will flower profusely, and much better than in the ordinary garden. *R. J. Gold A. Malby, Essex.*

The Week's Work.

THE KITCHEN GARDEN.

By JOHN LYNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

ONIONS.—The main crop of Onions may be sown as soon as the state of the soil permits. If the ground for this purpose was trenched early in the winter, the soil should now be forked over and allowed to remain loose until it is dry enough to crumble under the foot, when the whole surface of the bed should be trodden as even as possible, and raked level with a wooden rake. The drills should be drawn 15 inches apart and 1 inch deep. Let the seeds be sown thinly, lightly covering them with fine soil. Afterwards, the bed should be trodden very carefully and raked lightly, taking care not to disturb the seeds. There are many good varieties of Onion, but those of good keeping quality are the best for general use. At Windsor we grow about 2 acres of Onions, and we prefer those varieties which are known to keep best.

CARROTS.—Make a small sowing of Early Gem or some other stump-rooted variety on a south border, first breaking the ground very finely. Sow the seeds in shallow drills drawn at 9 inches apart, to allow the free use of a ditch hoe between the rows. Slugs are troublesome amongst early Carrots, but may be kept in check by frequent dustings of soot, which will also benefit the crop if applied in moderation.

TOMATOS.—If seeds were sown a month ago, the young plants should now be ready for potting. Employ a compost of loam and leaf-mould in equal parts. After potting, they should be placed quite close to the glass, in order to promote a stocky growth. Plants in fruiting-pots should be confined to single shoots, all side growths being removed as they appear. When the plants are in flower, special care should be taken to fertilise the flowers as they become ripe, by conveying the pollen from one to the other by means of a camel's hair brush or by frequently shaking the trellis on fine, sunny days. Sow seeds for raising plants for out-door cultivation, sowing them thinly in pans or boxes and placing them in a temperature of 65° until the young plants are well above the ground, when they should be placed near to the roof glass.

POTATOS IN PITS.—Air should be admitted freely to this crop during mild weather. Let the plants be earthed up as soon as they are 6 inches high. If sufficient space has been allowed between the rows, the soil may be drawn up to the stems in the usual way without injury to the roots, but if the limited space will not permit this operation, some old potting soil may be placed among the plants. Previous to the earthing up, the bed should be watered carefully with clear, tepid water. Further plantations should be made under glass to maintain a supply until tubers can be obtained from the garden. A small plantation of the variety May Queen may be made in a sheltered part of the garden, where a covering can be applied without being unsightly. Tubers intended for planting should not be allowed to remain together in large quantities after this date, or they will make spindly shoots, and their value for planting will deteriorate. The tubers should be laid singly in a well-ventilated shed, where protection from frost can be applied if necessary.

FRUITS UNDER GLASS.

By E. ECKERTY, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

THE ORCHARD HOUSE.—Make the house tidy and have everything in order so that it may be closed for starting the trees whenever required. Fruit trees in pots that have been plunged out-of-doors during the winter months in ashes or other materials must be lifted and prepared for housing. Plants that were potted last autumn will only require the surface soil to be cleaned and made tidy. Those that were not repotted should have a quantity of the surface soil removed and be given a good top dressing of a compost con-

sisting principally of loam. The soil should not be in too fine a condition, and a sprinkling of wood-ash, bone-meal, and mortar-rubble should be incorporated with it. The top-dressing should be pressed firmly. Examine the drainage, and wash the pots. The plants in Orchard houses containing a variety of fruits should be started into growth very gently. In the early stages of forcing the night temperature should not exceed 45° with artificial heat. An abundance of fresh air should be admitted throughout the day, and the trees started into growth as naturally as possible. Watering must be done carefully, and though an excess of moisture must be guarded against, the soil must never become dry. To ensure a proper degree of moisture at the roots much judgment will be required, especially when new compost has been placed on the surface of the pots. Keep the surroundings moist, and syringe the trees lightly on favourable occasions. Before the flowers expand, fumigate the house with XL-All vapouriser to destroy any aphid that may be present.

THE MUSCAT VINERY.—Vines of Muscat varieties require a long season of growth to properly mature the bunches, and, for general purposes, houses containing Muscat Grapes should now be closed. For a commencement, a night temperature of 50° will suffice, and it may be even lower during very cold weather. Maintain a moist atmosphere by frequently damping the bare spaces and spraying the rods once or twice daily according to the weather. Early vines of Muscat varieties that are approaching the flowering stage should have the growths stopped at two joints beyond the bunch, and, if the shoots are in danger of coming in contact with the glass, draw them down carefully and secure them with strands of raffia; if there is no danger of them touching the glass do not train them in for the present, as the flowers set better, and especially at the lower part of the rods when near to the light. At this stage ventilation must be afforded carefully, and, until the flowers commence to expand, a humid atmosphere must be maintained, with a night temperature of 65° to promote a strong growth. When the vines are in flower a rather drier atmosphere is required, but not excessive atmospheric dryness. The temperature may be slightly increased, but do not employ an excessive amount of fire heat, and much of the syringing and damping should be withheld, although on bright mornings, and when ventilation can be given without danger of a check, the border and paths may be sprayed. Muscat Grapes are very uncertain in setting the berries, therefore artificial pollination should be resorted to, either by tapping the trellis sharply, dusting the bunches with a rabbit's tail, or drawing them carefully through the hand.

LATE VINERIES.—These will now require closing, for if the vines are grown gradually they will furnish well-coloured bunches that will keep much better than those that have to be hurried at the last in order to get the berries coloured properly. In the case of Black Hamburgh, the vines will need retarding, as this Grape matures much quicker than most sorts, the houses may therefore be ventilated freely until the vines show signs of growth. Houses containing Gros Colmar, Lady Downes, and Lady Hunt will merely require to be kept closed at night time, freely ventilating them during the day. The vines must be sprayed frequently during fine weather to encourage them to break evenly, and the rods should be allowed to hang down to check the flow of sap to the top.

GENERAL REMARKS.—Examine carefully any bunches of Grapes still in the fruit room, and remove any berries that show signs of decay. Replenish the water in the bottles, and remove a portion of the old stalk with a sharp knife. Such plants as Melons, Strawberries, and Cucumbers require all the light possible at this season, therefore, with the aid of a flat brush or mop, attached to a stout bamboo rod, wash the roof glass thoroughly and rinse the panes afterwards with clear water. Make arrangements for obtaining a good supply of manure water for the fruit trees in pots. The drainings from a farm-yard, when obtainable, provide an excellent stimulant for plants in pots and borders, but it needs to be diluted. Failing this, cow manure mixed with soot should be placed in a coarse bag and dropped in a tank to provide liquid manure.

Endeavour to keep the borders in forcing houses free from weeds, and, once a week, lightly stir the soil with a fork. Oftentimes, and especially under trellises and stages where the drainings from pot plants fall, the border is apt to become soddened and sour. An occasional stirring of the surface promotes aeration and assists in drying the border besides disturbing woodlice and other ground pests.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

PRUNING WALL TREES.—The pruning of all kinds of wall fruit trees should be completed as quickly as possible. Peaches, Nectarines, and Apricots growing upon south walls are the most pressing, as the buds will soon be so advanced as to make it impossible to handle these without causing damage. Espalier and other trained trees in the open should next receive attention. Remove all the old ligatures, and tie the branches afresh, arranging them in such a manner that the sun and air may have free access to every part of the tree when in full leaf. Prune newly-planted trees, and stake all standard and half-standard trees, making them secure against high winds. Lately-planted bush trees, especially those on shallow soils, should be mulched before the advent of drying winds and sunny weather.

FRUIT TREE BORDERS.—Complete the digging and dressing of fruit borders as advised in a former Calendar. Bush fruit trees showing signs of weakness may be assisted by giving them a surface dressing of Guano or some other quick-acting stimulant; this is best applied during showery weather. The pruning of outdoor vines and Figs, whether growing on walls, pergolas or arches, should be completed during the present month, or bleeding will result if it is left until the sap is on the rise.

PROTECTION FROM BIRDS.—A sharp lookout should be kept for bullfinches amongst the Gooseberry and Plum trees at this season, for if left undisturbed, even for a few days, they will do much mischief. The gun should be brought into use. We have found sometimes, by spraying the trees at about this date with an approved "Bud Protector Composition" that the mischief usually wrought by small birds has been lessened.

PLANTING WALNUTS.—Walnut trees may yet be planted, and, unless the soil and situation are unfavourable, they will soon become established and rapidly grow into handsome trees of considerable size. They thrive best when growing in a rich, loamy soil with good natural drainage. Although the Walnut may easily be grown from seed, few growers now resort to this method of propagation beyond raising stocks, on which the choicer varieties are grafted, preferring rather to purchase from the nurseries worked trees that have been properly prepared for removal. The tap root is removed to make the tree more fruitful, and the branches trained to incline to an outward, rather than in an upward direction; trees so treated always spread their roots nearer to the surface of the soil, and are more satisfactory to deal with in every way. Sometimes a line of Walnut trees is planted at the end of an orchard to serve as a screen to other fruit trees; in this way they conveniently serve a double purpose if planted at about 25 or 30 feet apart. If planted on park land, the distance from tree to tree should be not less than 80 feet, that is, if fully-developed trees are desired, and especially if the trees are seedlings. If worked trees are planted, it may become necessary from time to time, to remove any growths that may appear below the point of union, otherwise the common stock will outgrow the more valuable variety. Like other fruit-bearing trees, the Walnut may, if showing signs of deterioration, be brought into a state of fertility by giving the trees a suitable top dressing or mulching of well-decayed manure. Although there are several varieties of the Walnut, which vary considerably in size, flavour, and fertility, the "Thin shelled" is now generally considered to be the best. The shells are well filled, and the nuts are of excellent flavour, whilst, if properly stored, they keep better than some other varieties.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, K.T., Tynninghame, East Lothian.

SPRING-FLOWERING BULBS.—Narcissi and other bulbs in beds are showing signs of growth, and it must be decided whether it will be advantageous to apply a dressing of superphosphate between the rows. This manure exerts a marked influence for good when Narcissi have been two or more years in the same ground. A sufficient dressing is as much as will cover the surface of the ground lightly. The soil should be dug at the time the manure is applied, and be very lightly forked over immediately afterwards. The same manure is sometimes beneficial for late Tulips, Spanish and English Irises. Lily-of-the-Valley should be top-dressed with a layer of fresh compost, applied evenly, $\frac{1}{2}$ inch thick. The finest variety of this popular flower is Fortin's, but here it has never been the success that it is on a heavier soil, nor does the Berlin variety succeed so well as the ordinary English sort, therefore do not root out the latter until it is seen how the others are likely to do.

LILIUMS.—Many species of Lily are unsatisfactory "doers." They grow all right for two or three years, and then dwindle away. The more useful kinds and easiest to grow are *L. pomponium*, *L. croceum*, *L. Martagon*, especially its varieties *album* and *Dalmaticum*, *L. chalcidonicum*, *L. tigrinum splendens*, and *L. tigrinum Fortunei* are valuable for an autumnal display. The last named sometimes flower too late in the North to be useful, but the other, though less stately, never fails. The bulbs of the Lilies may be planted at once, and it is well worth the trouble to stir the soil deeply before they are inserted, and to replace some of the natural staple with a turfy compost. The bulbs should be placed not less than 6 inches below the surface, and a much of exhausted Mushroom dung pressed through a fine sieve should be spread evenly over the whole. Much of the beauty of these Lilies lies in their stately stems and handsome foliage.

CELSIAS.—Seeds of *Celsia Arcturus*, *C. cretica*, and others should be sown at once in order to secure strong flowering plants. After the seedlings have been transplanted into boxes to gain strength, they should be kept growing in an intermediate house till the middle of April. The plants are, if not absolutely handy, at least practically so. Planted in a fertile soil *C. Arcturus* makes a fine addition to the border flowers in autumn, but the others are rather coarse-growing plants. *C. Arcturus*, *C. pontica*, and *C. coromandelina* have flowered the same year here from seeds sown in the open, but it is preferable to raise the plants under glass.

LARKSPURS.—Seeds of Emperor and Stock-flowered Larkspurs should be sown in boxes and germinated under glass in order to have plants in flower at a reasonably early date. The Stock-flowered is one of the most meritorious of the taller types of this plant for massing, Sutton's Rosy Scarlet being the most popular variety; Double Blue and Veitch's Branching Blue are also of much value. The plants are, unfortunately, liable to a root affection, which sometimes destroys them almost wholly. To lessen the effect, if not to prevent attack, the seedlings should be dibbled into the positions set apart for them while they are quite small, and as a precaution the surplus ones should be retained to make good any losses. These are varieties of *Delphinium consolida*, and are absolutely hardy. They have been cultivated in gardens since the 16th century. Some of the Rocket Larkspurs (*D. Ajacis*) are also pretty, but they should not be sown till April, and then in places where they are to flower. Other plants that require sowing now include the large-flowered varieties of *Scabiosa*, *Statice Suworowii*, which should be very strong when planted out to obtain the best results; *Perilla Nankinensis*, *Polygonum orientale*, this also needs to be well advanced at the time of planting; *Chamaepeuce diacantha*, and any others requiring a long period of growth before they are finally planted.

GRASS PATHS.—In not a few walled gardens grass paths have been substituted for gravel paths, and always to the enhancing of the effect of the borders they separate. There is not much difficulty in transforming a gravel into a grass walk.

Those which I have altered have merely had the hard gravel loosened with a pick, levelled, and a layer of soil placed on the top to bring it to the higher level necessary for sowing the grass or placing the turves. The seeds may be sown any time after the middle of March, but a turf of fine grasses, where it can be procured, is to be preferred for immediate effect and use.

THE ORCHID HOUSES.

By H. C. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

EPIPHYTAL ORCHIDS.—Plants of *Vanda*, *Aerides*, *Angreecum*, and *Saccalabium* are commencing to grow again, which may be seen in the activity of the roots. All these plants require fresh rooting material annually, but healthy established specimens need not be disturbed beyond having all the old material picked out from amongst the roots, an operation that should be performed without damaging or unduly disturbing the latter, especially those that are clinging to the receptacle. All decayed roots should be cut away, and the sound ones re-laid amongst the new material, at the same time burying the ends of any long, aerial roots present. Specimens that have become ungainly through loss of foliage should, after the soil has been carefully shaken away, have sufficient of the lower portion of the stem removed to allow the plant to be placed deeper in the receptacle, so that when it is repotted the lower leaves are on a level with the rim of the receptacle. Ample drainage should be afforded the plants, and the compost should consist of equal parts *Osmunda* fibre, *Polypodium* fibre, and *Sphagnum*-moss, with a liberal addition of coarse silver sand, finely broken crocks, and charcoal, well mixed together. Pot moderately firmly, and finish with a layer of clean-picked fresh *Sphagnum* moss. For a time, and until growth becomes active, water must be afforded the roots sparingly, but there should be plenty of moisture in the atmosphere. The majority of these Orchids are best accommodated in the warmest division of the Orchid houses, but they are sometimes found growing well in a house having an intermediate temperature. *Vanda cœrulea* is usually a difficult plant to cultivate satisfactorily for any great length of time. Like many more in the genus it is a free-blooming, healthy-growing plant under favourable conditions, but, unfortunately, it is not always easy to find the position and conditions which suit it best. During this season the plants may be accommodated in any light, airy house, where they can enjoy plenty of heat by day, with moisture and air in abundance, whilst at night time they prefer a cooler temperature. *V. Amesiania*, *V. Kimballiana*, and *V. Watsonii*, are three dwarf-habited species that thrive under similar conditions to *V. cœrulea*, but in a cooler day temperature. When the weather is bright, shading is necessary, but when the plants are established the light they receive must not be too much subdued, or the foliage will not be so healthy and solid, and flowering will be unsatisfactory.

RENANTHERA IMSCHOOTIANA.—This fine, showy species thrives well in the *Cattleya* house. The plants do well in pots placed on the stage or in baskets suspended from the roof-rafters. These are now exhibiting signs of fresh growth, and the affording of new rooting material should receive attention forthwith. The compost and procedure in potting should be similar to that advised for the Epiphytal Orchids.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

STOVE PALMS.—*Hvophorbe* (*Areca*) *lutescens* is an excellent Palm for many purposes. Both this species and *Cocos Weddelliana* should be kept during the winter in a hot plant house, but in the summer they may be used freely for decorations like *Kentias*. Such Palms thrive well in quite small pots, and the cultivator should guard against over-potting. Through careless potting and unsuitable soil many a *Cocos* is quite ruined. *Enterpe edulis* is another valuable Palm for vases of moderate size, and it is quite distinct with its graceful and arching foliage. Examine

all the Palms and only repot those that require more root space. Palms are often troubled with scale insects whilst they are kept in a stove temperature, but these can be destroyed by careful sponging.

CALADIUM.—If the *Caladiums* have been stored in the pots in which they were grown last season, the tubers may now be shaken out of the soil and cleansed of any decaying matter. *C. argyrites* is very useful in many ways, too, therefore an increase in the stock may be found serviceable. I prefer to start this variety dibbled into seed pans, potting them up later on when they have made some growth. The smaller bulbets are quite useful in thumb-pots, and even those of a larger size must never be overpotted. If a wall in the stove has to be covered with varied growths, a few plants of *Caladium argyrites* will be of service for the purpose. The larger-growing *Caladiums* should also be started into growth in small pots, and some at least should be kept in small pots for furnishing. The aim should be to grow more of those with moderate-sized foliage and compact habit rather than the more robust varieties.

GLOXINIA AND ACHIMENES.—The seedling *Gloxinias* of last year, and any older corms, should now be shaken out, carefully examined and repotted into smaller pots than those in which they were flowered. After potting, give one watering, and afterwards be careful not to apply much moisture until active growth is manifest. *Achimenes*, not now so much grown as formerly, are nevertheless useful decorative plants in 6-inch pots, whilst the more scendant varieties are of considerable service as basket plants in the stove, and also in the conservatory during the summer months. *Achimenes* should be shaken out of the soil in which they have been grown and each corm carefully dibbled into shallow pans. When they have grown 2 or 3 inches high they may be transferred to their flowering pots or to baskets and placed near to the glass. Some of the plants should be kept cool to form a succession.

BEGONIAS.—Varieties of the *Gloire de Lorraine* section should now be looked after for propagating purposes. If the growths have not been cut down, do not lose any time in getting this done. See that the stock is kept quite free from insect pests, otherwise the troubles with these will increase rapidly. We prefer to propagate from basal shoots rather than from leaves. Each cutting should be inserted into a thumb-pot containing sandy soil. If the stock is short then leaf-cuttings can also be taken. Our plan used to be to insert each leaf with its petiole intact, one plant will result in this way from one leaf, not as in the case of the *B. Rex* varieties, which produce young plants from the leaf veins. The stock of the "Rex" varieties may now be increased in the way mentioned or by division. The tuberous-rooted varieties should be shaken out and repotted, keeping them somewhat cooler than the others, and keeping them in batches to flower in succession.

THE APIARY.

By CHLOEIS.

FEEDING.—The honey season in 1910 was a very bad one, and, unless sufficient artificial food were given the bees last September, there is a danger that they will die from starvation between now and the end of March. Whenever a fine day occurs, apiarists should place a cake of candy under the quilts. Breeding is proceeding, and an increasing number of young bees will be hatched daily, so that there will be an extra demand for food. When brood-rearing has commenced and the supply of pollen is short, it is advisable to give the bees some pea-flour. It should be mixed with some shavings and placed in a warm corner, where the sun can shine upon it.

PLACING OF ORDERS FOR MATERIALS.—Many beekeepers delay ordering their requisites until something is required urgently, and then they find fault with the manufacturers because they are kept waiting for the goods. Some makers of beekeeping requisites offer special terms to those who order before the middle of March, when the rush of trade generally commences, so that ordering early has a double advantage.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but they cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 28—

Roy. Hort. Soc. Coms. meet. (Fifth Masters' Memorial Lecture at 3 p.m., by Mr. G. F. Scott-Elliott, M.A., on "Recent Work in Seed Selection.")

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—40.4°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 22 (6 P.M.): Max. 51°; Min. 45°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, February 23 (10 A.M.): Bar. 29.5; Temp. 49°; Weather—Dull.

PROVINCES.—Wednesday, February 22: Max 50° Ireland S.E.; Min. 40° Scotland, N.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Herbaceous and Border Plants, Hardy Bulbs and Roots, at 12; Roses, Fruit Trees, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—

Hardy Bulbs, Perennials, Border Plants, &c., at 12; Roses, at 1.30. Trade sale of Miscellaneous Bulbs and Plants, at 12; Japanese Lilies, at 2.30. Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

Choice Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Wart Disease of Potatos. The most recent, and, in many respects, the most valuable, contribution to our knowledge of wart disease of Potatos is contained in a recent bulletin issued by the Harper Adams Agricultural College. The bulletin records the results of experiments made by Messrs. Malthouse & Williams, and its special value lies in the proof which it appears to afford that certain varieties of Potato are immune from the disease. The experiments and observations described in the report cover a considerable amount of ground, and deal with the effects of fungicides and of soil dressings on the disease, the modes whereby wart disease spreads, and its present geographical distribution in England and Scotland. Horticulturists generally are greatly indebted to Mr. Belleville Stanier, M.P., who not only proposed to the authorities of the Harper Adams College that they should undertake this experimental inquiry, but who also bore the cost both of the inquiry and of the publication of the present bulletin. Public-spirited generosity of the kind exhibited by Mr. Stanier is to be encouraged, and it is therefore particularly gratifying that this instance thereof has resulted in information of considerable practical value.

Wart disease is due to the infection of the Potato by a micro-organism (*Synchytrium endobioticum*, Percival), which gains access to

the tubers from the soil. Though it is probable that there is yet more to be learned of its life-history, the essential fact is well established that, as is the case with the organism responsible for "Finger and Toe," the infecting stage of the wart disease organism consists of motile spores. The diseased tuber contains large bodies (sporangia), each of which encloses vast numbers of spores. When the tuber rots, the sporangia are set free in the soil, their walls burst, the spores are liberated, and from each spore there escapes a minute, flagellated organism which is able to move through moist soil and to penetrate and infect a new host. Whence it follows that the disease is distributed in two main ways, namely, by "seed" and by soil. Diseased tubers used for seed may not only produce diseased plants, but may serve as centres for soil-infection. Again, diseased tubers fed to pigs or other stock may lead to further soil infection through the manure. Infested soil may also spread the disease, for any agency which distributes the soil—implements, workers on the soil, poultry and so forth—may distribute the resting sporangia. We dwell upon these matters, which are well brought out in the report, because it is evident that control of this, as of any other disease, depends on a knowledge of the mode of life of the parasitic agent which produces it. A further point which deserves notice is that the disease may progress in the tubers after they have been lifted and stored. It follows, therefore, that "clean seed" must be used, that is to say, seed from a region where the disease is unknown; for tubers from a diseased field, though they do not show the external signs of wart disease (*Gard. Chron.*, July 31, 1909, figs. 33, 34) may nevertheless carry it. It follows also that, till preventive methods are discovered, infected land should not be planted with Potatos, at all events in the following season. Another matter of practical importance, to which attention is drawn in the report, requires emphasis; that is, that boxing and greening the Potatos tend to lessen the risk of diseased tubers being planted. For, evidently, the symptoms of the disease will have had more time to manifest themselves in tubers which have been treated in this manner than in those which are purchased just before sowing. A further method of combating the wart disease consists in giving the widest publicity to its existence and nature. Thus it is significant that the malady is much more widely spread in allotments and gardens than in the field, a fact that suggests that many small cultivators are unaware that tubers with wart like excrescences are anything more than interesting curiosities.

As is to be expected from a knowledge of the life history of *Synchytrium endobioticum*, spraying the crop with various fungicides fails to arrest the progress of the disease. The more promising method of preventive treatment, that of drenching the soil with a fungicide with the object of destroying the motile spore, has unfortunately not given decisive results. There is, however, some evidence that soil-spraying with copper sulphate in July produced beneficial effects, and it is to be hoped that further experiments in this direction will be made. Associated with these various methods designed to prevent the motile spores from reaching the tubers is the

practice of earthing up, which practice, as the report makes clear, has a decidedly beneficial effect on Potatos grown in infected land. But, as we have already indicated, the most promising method of prevention consists in the planting of immune varieties, and it is encouraging to find that, according to the various trials which have been made at Newport, immune varieties not only exist, but are also fairly common. We cannot give here the complete list of immune varieties (see p. 122), but may note that it includes Longworthy, Discovery, Southern Star, Peacemaker, Laird, White City and many others. The final selection made by Messrs. Malthouse & Williams is as follows:—Early: Aberdeen Early, Milecross Early. Second Early: Abundance, Conquest. Maincrop: Provost, Crofter, Golden Wonder and What's Wanted.

Among the most interesting features of the report is a series of maps showing the geographical distribution of wart disease. A glance at the map of Great Britain shows that the disease has spread north and south till it extends now through a section of the western and western-midland counties from Perth to Warwick. So far, the whole of the East Coast counties of England remain free from the disease, as do also the counties south of a line drawn from the estuary of the Severn to the Wash. The interesting enquiry is thus opened up, whether the wart disease is closely associated with some special geological or climatic conditions? In conclusion, we commend this excellent report to all our readers interested in Potato cultivation, and have only one or two minor adverse comments to make. First, we suggest that the bulletin should bear a number for purposes of reference, and second, we confess to being puzzled by the cryptic remarks (p. 40) with respect to the possibility of other crops being attacked by wart disease. We read that Finger and Toe has been suspected to be identical with wart disease, and that the nodules of leguminous crops have been subject to like suspicion. For our part, we know of no particle of evidence for either suggestion, and unless the writers have some serious evidence in their favour, we think that it would be wiser to refrain from giving currency to hypotheses of which the latter at all events must, in the present state of our knowledge, be regarded as fantastic.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees of this Society will take place on Tuesday, the 28th inst. At 3 p.m. the fifth "Masters" Memorial lecture will be delivered by Mr. G. F. SCOTT-ELLIOTT, M.A., F.R.S., V.M.H., on "Recent Work in Seed Selection."

ONE THOUSAND POUNDS FOR SWEET PEAS.—The *Daily Mail* has announced that it will hold a show in the month of July next, when prizes will be given for bunches of Sweet Peas, consisting of not more than 12 sprays, and each bunch representing not fewer than three varieties. The 1st prize for the best bunch will be £1,000, 2nd prize £100, and the 3rd prize £50. A thousand medals will also be given. Those who grow flowers for profit and amateurs who employ more than one gardener are debarred from the competition. In case the judges should not be able to choose between two or more competitors, the prize or prizes will be awarded to the competitor or competitors exhibiting Sweet Peas grown without the assistance of a gardener.

Photographs by W. J. Vasey.

VIEWS IN THE GARDENS AT BARON HILL, BEAUMARIS, THE RESIDENCE OF
SIR RICHARD H. WILLIAMS-BULKELEY.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—The spring exhibition of the society will take place on Wednesday and Thursday, April 5 and 6, in the Waverley Market, Edinburgh. The show will remain open until 10 p.m. each day. The schedule embraces some 135 classes, and there are sections for plants, cut flowers, fruits, and vegetables. The most valuable prizes are offered for groups of plants. As on former occasions there is a competition, open to under gardeners only, for laying out a portion of land as pleasure ground and kitchen garden, an outline sketch of the estate being furnished.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The members of the Liverpool Auxiliary will hold their 10th annual concert in aid of the funds of the Institution on March 3. The treasurer, Mr. HARRY J. VEITCH, V.M.H., will preside, and the secretary, Mr. GEO. INGRAM, will be present. Mr. R. G. WATERMAN, Woolton, is the hon. secretary for the Liverpool district.

ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.—According to a paragraph issued by the Hon. Press Secretary, Mr. R. HOOPER PEARSON, several valuable cups have been presented for competition at the Royal International Horticultural Exhibition to be held in May, 1912, at Chelsea. Amongst the donors are: the Treasurer (Sir JEREMIAH COLMAN, Bart., V.M.H.); the Chairman of the Executive Committee (Mr. J. GURNEY FOWLER); the Worshipful Company of Fruiteers; and the Worshipful Company of Gardeners; the Proprietors of the *Gardeners' Chronicle*; Messrs. SANDER & SONS, St. Albans; J. CHARLESWORTH & Co., Haywards Heath; DOBBIE & Co., Edinburgh; BARR & SONS, Covent Garden; and GEORGE BUNYARD & Co., Maidstone. Others wishing to contribute cups should communicate with the Hon. Secretary, Mr. EDWARD WHITE, 7, Victoria Street, Westminster, or Mr. HARRY J. VEITCH, Chairman of the Schedule Committee.

—A Science and Education Committee has been appointed to promote a congress and advance the scientific section of the exhibition. The Chairman of this Committee is the Rt. Hon. A. H. DYKE ACLAND, P.C., and Mr. E. J. CHITTENDEN will act as Hon. Secretary. The members include: E. A. BOWLES, Chairman of the Royal Horticultural Society's Scientific Committee, Professor WILLIAM BATESON, F.R.S., Prof. BAYLY BALFOUR, F.R.S., Sir THOMAS ELLIOTT, K.C.B., ANDERSON GRAHAM, Dr. BRET-LAND FARMER, F.R.S., GEORGE GORDON, V.M.H., H. RIDER HAGGARD, Sir EVERARD IM THURN, K.C.M.G., Dr. D. JACKSON, F.L.S., Dr. F. KEEBLE, M.A., DONALD MACDONALD, W. MARSHALL, V.M.H., FRED W. MOORE, M.A., SPENCER PICKERING, F.R.S., Lt.-Col. D. PRAIN, C.I.E., F.R.S., Dr. A. B. RENDLE, M.A., B.Sc., T. A. H. RIVERS, A. G. L. ROGERS, E. S. SALMON, ARTHUR W. SUTTON, V.M.H., Prof. SOMERVILLE, HARRY J. VEITCH, V.M.H., Prof. S. H. VINES, D.Sc., F.R.S., and Rev. W. WILKS, M.A.

BOSKOOP POMOLOGICAL SOCIETY.—We have received further particulars of the flower show which will be held at Boskoop in April, to celebrate the jubilee of the Boskoop Pomological Society. It will consist largely of forced shrubs and perennials, and will be accommodated in a heated building that will be illuminated during the evening by electric light. The committee has received already a large number of entries, including more than 100 for novelties. The nearest railway station to Boskoop is Gonda, and, during the time of the exhibition, there will be a steamboat service hourly between the two places. A committee consisting of 40 members has been appointed.

TURIN INTERNATIONAL EXHIBITION, 1911.—In connection with the forthcoming international exhibition at Turin, a permanent horticultural exhibition will be held from April to November, 1911, and also three temporary shows. The permanent section forms part of the general exhibition, and includes matters relating to the cultivation of fruits, vegetables, and flowers; garden implements and tools; and teaching and appliances for teaching. The three temporary flower and fruit shows will be held as follows:—Spring show, May 15 to 25; summer show, September 16 to 24, and the autumn show, October 25 to November 4. Copies of the regulations and schedules relating to these shows may be obtained from the Secretary to the Horticulture Committee, 21, St. James's Square, S.W.

ROYAL WARRANTS FOR NURSERY AND SEED FIRMS.—We are informed that the Royal Warrant of Appointment to the King (see pp. 90, 105) has been conferred on Messrs. SANDER & SONS, Orchard Growers, St. Albans. Messrs. THOMAS GREEN & SON, LTD., Leeds, have received the Royal Warrant of appointment as horticultural machine makers to the King, and Messrs. DICKSON & ROBINSON, Manchester, have been appointed seedsmen to her Majesty Queen Alexandra.

PLANT PHYSIOLOGY AND PATHOLOGY.—Professor V. H. BLACKMAN, M.A., Sc.D., formerly Hutchinson Research Student and Fellow of St. John's College, Cambridge, and Walsingham (Biological) Medallist of the University, who has since 1907 occupied the Chair of Botany in the University of Leeds, has been appointed to the Professorship of Plant Physiology and Pathology at the Imperial College of Science and Technology at South Kensington.

PROTECTING SEEDS.—The season when some sort of protection will be necessary for small seeds in the kitchen garden being at hand, Mr. ELLISON sends us a sample of the Dunsmore Gosamer Seed and Plant Protector. This is a half-circular metal disc with notched edges and steel feet for inserting in the ground. Most gardeners employ wire-net guards, or fish netting to keep off birds, but some adopt the more simple device of strands of cotton or thread secured to pegs of wood. These metal discs are said to have an advantage over wooden pegs for securing the cotton or thread.

MUNICIPAL GARDENERS AND THEIR WAGES.—The Parks and Open Spaces Committee of the London County Council recently intimated to the Education Committee that they proposed to recommend the Council to increase by 2s. a week each, as from April next, the wages of three gardeners in charge of the Botanical Gardens at Victoria Park, Battersea Park and Horniman Gardens respectively during such time as these men were employed on their present duties. The Committee stated that they were advised that these men were highly qualified in gardening work, that they had carried out in a most satisfactory manner their duties, which, having regard to their educational character, required special knowledge and ability, and that they had also proved of considerable assistance to students using the gardens. The Parks Committee also expressed the opinion that the additional expenditure involved in the proposal should be charged against the education account, and asked the Committee to concur in the course proposed, and to arrange for the grants from the education account in respect of the maintenance of the gardens to be increased by the extent of the additional remuneration. Provision has been made in the annual maintenance votes for the current financial year for the sum of £170 to be transferred from the education account to the

general county account in respect of the use made for educational purposes of the botanical beds at Victoria Park and Horniman Gardens. In the draft maintenance estimates for the financial year 1911-12, the sum of £255 has been provided for similar purposes in connection with the three parks referred to by the Parks and Open Spaces Committee. This sum, the Education Committee think, is quite adequate as an inclusive payment in respect of the facilities afforded at these parks. At the meeting of the Education Committee on February 15, it was decided to inform the Parks and Open Spaces Committee that the Committee regret that they are not prepared to agree to the increase.

THE KEW GUILD "JOURNAL."—The members of the Kew Guild are to be congratulated on the number of the *Journal* recently published. It contains much information upon the happenings in the Royal Gardens, Kew, explains recent alterations and additions, gives lists of appointments and retirements, and interesting notes upon the doings of Kew men in various parts of these islands. This is the kind of news that makes the *Journal* so valuable to Kew men in India and the Dominions, who are thus enabled to maintain touch with horticultural activities at home. In return for this many of the oversea members contribute descriptive letters from their own stations, and these are excellent reading for gardeners who have no personal experience of any other vegetation than that of a temperate clime. There are letters from Zomba, Nyassaland, Portuguese East Africa, United States of America, Singapore, and other places. Kew men are widely distributed; as Sir William Dyer once said, "They dot the Cape to Cairo Railway," and representatives of the Kew Guild may be found in every quarter of the globe. It is this fact that makes the *Journal* so much appreciated, for it serves as a link, uniting the older men who are taking their part in the work imposed by the responsibilities of Empire, with the youngest members now in training at Kew. The present issue, which has been prepared by Mr. HERBERT COWLEY, the new Secretary and Editor, is so much enlarged and so interesting that it compensates in some measure for the non-appearance of the *Journal* last year. The frontispiece is a portrait of Mr. R. HOOPER PEARSON, who forms the subject of a few personal notes by "W. W."

THE NATIONAL VEGETABLE SOCIETY.—The Society's pamphlet containing the schedule of prizes to be offered at the second annual exhibition of vegetables on August 30 next comprises 40 pages. There are some 80 classes, which are so varied in character as to encourage exhibits from every description of grower. The Duke of PORTLAND (the president) repeats his prize of 10 guineas in the first class for a collection of 12 dishes, and Lord HOWARD DE WALDEN adds a second prize of seven guineas, the Society adding a third prize of four guineas. A class for nine dishes follows, and Lord NORTHCLIFFE gives prizes to the value of £12 in two classes, one for six dishes of vegetables and one for six dishes of Tomatos. Mr. GEORGE MUNRO's prizes are offered for Tomato plants in pots, those of *Country Life and the Garden* for six dishes of Peas, and Messrs. CLAY & SONS offer prizes for six dishes of Potatoes. The Chairman continues his prizes for Surrey cottage gardeners and allotment workers. A large number of firms offer prizes for classes in which the competition is more or less restricted. Finally, there are 18 classes for amateurs and cottagers. The trials report is included. Those wishing for copies of the schedule should write to Mr. E. J. QUICK, "KelmScott," Harrow View, Wealdstone.

BARON HILL, ANGLESEY.

(See figs. 59 and 60, also Supplementary Illustration.)

BARON HILL, the residence of Sir Richard II. Williams-Bulkeley, is situated near Beaumaris, on the banks of the Menai Straits. Those who have passed through this narrow stretch of water will recall the beautiful scenery of the Anglesey and Welsh coasts which border it. Anglesey appears to be covered with beautiful woodlands, whilst, on the Carnarvon side, rises in majestic splendour almost from the water's edge, a range of mountains that run through the centre of Wales. Baron Hill nestles amongst the woodlands, and is reached by a road which runs along the coast-line from Menai Bridge towards Beaumaris, and is overshadowed for miles with Oak trees. The residence at Baron Hill is situated a distance of two miles beyond the entrance to the grounds, and is reached by a carriage drive. My first visit was made in summer time, and I found, immediately on entering the gates, groups of Veronicas and Fuchsias in bloom, with a background of Hollies, conifers, and Beeches. The long road-

road passes beneath the dense shade of Beech trees, and later the scene opens out, affording a view of the town of Beaumaris, with its ancient Ivy-covered castle. There are yet two bridges which must be passed before the mansion is reached. The ground rises to a considerable height in front of the main entrance of the residence, and is planted with groups of Rhododendrons, amongst which are intermingled very large plants of Fuchsias, some of them being 15 to 20 feet in height. Between the groups of flowering shrubs, are patches of Heather which show well against a background of graceful trees at a higher level. A part of the pleasure grounds near to the house is known as the "pulpit" garden, from a stone structure, on either side of which is a row of Laurels 12 feet high. A gravel path runs at right angles to the "pulpit," and divides the garden in two parts. On either side of this pathway are flower-beds cut in the turf. In summer time, they are planted with Antirrhinums, Larkspurs, Godetias, Gladioli, Nigella, and other plants of this type. An oval bed in the centre is furnished with sub-tropical

bounded by a stone wall. This wall is covered with Rambler Roses, and between the shoots of the Roses Ferns peep out from many crevices. Vases are arranged at intervals along the wall, and are filled with suitable flowering plants. At the base of the wall is a mixed border planted with herbaceous subjects. Numerous rambling Roses are trained to brick columns about 3 feet high and 14 inches square. From the Rosary, the pathway leads to a Cedar walk, and this leads in turn to the terrace garden (see fig. 59). This latter is formed of beds of various shapes, most of them being outlined in Box. In summer time they are filled with Pelargoniums, Heliotropes, Petunias, Calceolarias, Begonias, and other showy bedding plants; each bed having only one kind of plant. The hedges of Myrtles, some of them 10 feet high, Pittosporum Tobira, Choysia ternata, Oleandra fragrans, and Ceanothus are conspicuous objects. On the sides of the steps which lead to the terrace garden are specimens of Aloysia citriodora (Lemon plant), more than 10 feet high. Two large Bay trees growing in iron boxes stand at the top of the steps. The climate is so genial in this region, that Ivy-leaved Pelargoniums, trained up the walls of the mansion, live throughout the winter. On the lawns are to be found at intervals Camellias, Palms, Dracaenas, Bamboos, Pampas Grass, Myrtles, Fuchsias, Azaleas, Yuccas, Acers, Maples, Gunnera manicata, Hydrangeas, Magnolias, and others. In the midst of woodland is a side walk, leading to a nook cut in the rocks, wherein is a sarcophagus containing a stone coffin. Near by this spot Ferns grow in great numbers, making a natural Fernery. A number of Alpines have been planted amongst the Ferns, and by a pool, water-loving plants, such as Montbretias, Spiræas, Iris and Liliums, brighten the surroundings with their showy flowers.

The kitchen gardens are situated in a lower part of the grounds, at some distance from the house, and contains extensive ranges of glass-houses. Mr. R. Carter has been gardener at Baron Hill for the past two years. F.

FIG. 59.—BARON HILL: THE TERRACE GARDEN.

way passes in places between the solid rock, which had to be removed by boring and blasting; sometimes it is diverted to avoid rugged points which every now and again present obstructions. At other places it skirts a sloping bank, which is planted at intervals with groups of Rhododendrons and common and Portuguese Laurels, these shrubs being clipped in a dome shape. The bank rises in places to a height of 300 feet above the roadway, which is flanked on the opposite side by a dwarf wall. Ivy and numerous Ferns grow on this wall. Looking downward from the roadway, the landscape is seen to be covered with trees that appear to reach to the water's edge.

The scenery constantly changes as the visitor traverses this long drive; here and there are to be seen perpendicular rocks, in front of which hang festoons of Ivy, their summits being crowned by aged trees of Fuchsia, which spread out their graceful shoots laden with blossoms. In other places, the banks are covered with bushes of Escallonia, which were in flower, and, further on, were masses of Rhododendrons interspersed with variegated Hollies. At one point is a beautiful dell, with a natural waterfall. The

plants, and other beds contain standard Roses. Turning to the left, and passing between an avenue of standard Rhododendrons, the part of the grounds shown in the upper picture of the Supplementary Illustration is reached. There are some exceptionally fine trees at this spot, including three large specimens of Araucaria imbricata, one of which is shown in the picture. There are also imposing specimens of Cryptomeria japonica, Sequoia gigantea (Wellingtonia), and Cedars. Continuing in this direction, the visitor reaches a garden containing a Lily pond (fig. 60) and herbaceous borders, surrounded by a large clipped Yew hedge, over which Tropæolum speciosum creeps in summer time. Some ornamental iron gates lead to a herbaceous garden, but if the opposite direction is taken, a good view of the summit of Snowdon may be obtained through an opening in the trees. The Palm garden (see Supplementary Illustration) is planted with a variety of Palms, Dracaenas, Bamboos, Aralias, Fuchsias, Yuccas, Acers, Andromedas, Phormium, and other sub-tropical species. The garden is surrounded by hedges of Fuchsia and Myrtle. Near to the Palm garden, is a Rosary, situated on a slope, the higher side being

WART DISEASE OF POTATOS.

A BULLETIN issued recently from the Harper Adams Agricultural College, Newport, Salop, deals very fully with this subject (see p. 120). The college authorities in part at the request of the Board of Agriculture have carried on during the seasons of 1909 and 1910 a series of experiments to discover *first*, the varieties that are immune to the disease; *second*, the result of the application of certain fungicides.

In looking over the varieties reported on both in 1909 and 1910 one is struck with the fact that all varieties of the Up to Date type seem most susceptible to wart disease. In short varieties, which are the farmers stand-by and are the best resisters of the ordinary Potato disease (*Phytophthora infestans*), are most liable to suffer from this new wart disease or black scab (*Synchytrium endobioticum*), and some varieties of the Abundance type which succumb quickest to the old or ordinary Potato disease are resistant to the wart disease. Why should this be? It is just here that accurate pedigrees would be helpful. Varieties of the Langworthy type again are resistant both to the old and the new disease, and they, as all growers know, are quite distinct from both the Up to Date and Abundance types.

In 1910 the Harper Adams College trials embraced 57 varieties, nearly all in duplicate. Those which were immune were:—

Early varieties.—Aberlady Early, Milecross Early, Snowdrop, Southern Queen, Southern Star, Twentyfold.

Second early varieties.—Abundance, Conquest, Dobbie's Favourite, Supreme.

Maincrop varieties.—Chiswick Favourite, Crofter, Discovery, Golden Wonder, Laird, Langworthy, Prolific, Provost, Reading Giant,

Rector, Schoolmaster, White City, Peacemaker, What's Wanted.

The crops of some were very poor, and the report puts forward the following eight varieties as the best in their respective classes:—

Early.—Aberlady Early, Milecross Early (for rapid maturing).

Second early.—Abundance, Conquest.

Maincrop.—Provost, Crofter, Golden Wonder, What's Wanted.

Some thoroughly practical suggestions are made as to the mitigation of the ravages of the disease: "The application of raw nightsoil tends to increase the severity of the attack." "Ridges should be well crowned up and no hollow left at the top." "The indiscriminate use of tools on infected and clean ground is to be deprecated." "Poultry should not be allowed to roam over infected plots and clean ground." "Diseased tubers should not be used for pig feeding." These are a few of the trite hints set forth. *W. Cuthbertson.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE R.H.S. JOURNAL.—The remarks upon this subject made by Mr. Elwes at the annual meeting will be echoed very sincerely by many members, and thanks are due to him for calling the attention of those in authority to this matter. Now that the library, thanks largely to his efforts, has been placed upon a sound footing, the *Journal* is, without doubt, the most pressing question. It must be realised that the Society is attempting to supply in one publication the needs of two different classes of readers. The amateur is, of course, interested in the cultural and descriptive articles, and the ethics of rock and water gardening are to him questions of the gravest import. Another section of amateurs is doubtless interested in details of elementary botanical study, but these may be found in any primer dealing with this subject, and are certainly not suitable matter for a quarterly journal. The other class of reader is found in smaller numbers, perhaps, but the geographical distribution of the species is wide. It is for this class that the *Journal* offers but little material, and this little, it would seem, in a diminishing quantity. For example, the Society did great service in translating and publishing Mendel's epoch-making paper, but since then the student of heredity has a steadily-diminishing cause to refer to the files of the *Journal*. The description and registration of the hundreds of new plants introduced are not treated in a systematic manner, and are left to the chance of private trade members' efforts, with the result that much information obtainable at the date of introduction is lost. The neglect of fruit in recent times, as compared with the great interest shown in the days of Knight, Salisbury and Thompson, is conspicuous, and if it be charged that public interest is not now so keen as it was—a debatable point—the answer can surely be made that it should be the object of the Society to direct, as well as follow, horticultural tastes. The more punctual publication of the *Journal* at the present time should make it an attractive medium of publicity to the scientific worker, but one notes with regret the few original papers now contributed by the worker in the borderlands of horticulture and botany. Many features, such as the "Science Abstracts," are of great value, and if these and scientific and botanical papers were published, as Mr. Elwes suggests, in a separate form and under the supervision of a publication committee, it would, in the writer's opinion, greatly increase the utility, as well as the prestige, of the Society. *A Fellow.*

SAXIFRAGA × CLIBRANII.—There is no perplexity that besets the amateur more constantly than *Pembarras de choix*, the difficulty of choosing the best from the excessive abundance and multiplicity of varieties in the different species of flowering plants. In no group has more variety been developed of late than in the red-flowered, mossy Saxifragas. We were delighted some years ago by the appearance of "Guildford Seedling," and a charming little plant it is; but it has been quite eclipsed, both in flower and foliage, by the variety called after the raiser, *S. Clibranii*. This plant has a very robust constitution, increasing rapidly, and its foliage, consisting of closely-set rosettes of grass-green colour, is particularly decorative in winter, and never turns rusty in summer. The flowers are set on firm, erect stalks 5 inches or 6 inches high, and are of a deep, clear rose colour. In the original *S. Rhei* and *Guildford Seedling* the colour is fleeting, fading away when exposed to sunshine. I have *S. Clibranii* in various exposures, and although when facing full south the blossoms do get paler with age, they keep their beautiful colour longer than any other variety known to me. When cultivated in positions facing west or

best. Will anyone argue that price is remunerative? Taking English varieties of desert Apples, what is there that is worth eating after Cox's Orange Pippin is finished at Christmas? It is all very well to praise varieties like Baumann's Red Reinette, Sturmer Pippin, Lord Burghley, and the many other so-called late dessert Apples, but none of them is comparable to Winesap, Golden Newtown, White Winter Pearmain, Golden Russet, and other foreign sorts obtainable in magnificent condition after Christmas. The British grower is not altogether to blame for his inferior fruits. In British Columbia, the Wenatchee Valley, for example, no rain falls from the end of July until the fruit is gathered; the district enjoys a cloudless sky and brilliant sunshine. What have we experienced during recent years: more often rain than sunshine, and that during the most critical period. Climate is the salient point in the whole question, and over that we have no control. Quite recently I was talking to a grower from British Columbia who has a fruit farm of 160 acres, and he said it was merely a question of climate, soil, irrigation, and an enforced system of spraying that was responsible for the great success which

FIG. 60.—WATER-LILIES AT BARON HILL.

north-west, the flowering season is greatly prolonged, and the bright colour does not fade. *Herbert Maxwell, Monroith.*

IMPORTED V. HOME-GROWN APPLES.—Only those who grow English Apples for sale and those who are in business as fruiterers are capable of giving an opinion as to whether English Apples can be grown and sold at a profit in competition with the imported Apples. Persons who judge from exhibits of fruit staged at the R.H.S. meetings by nurserymen for the purpose of selling their trees are not qualified to express an opinion on the subject. What loss must have occurred between the time such fruit was first stored and when it was shown? What was done with those of second quality as none but the best specimens would be reserved for exhibition? The opinion expressed in one line from *Southern Grower* contains more weight than a column from *A* on this subject. Does it pay the ordinary grower to store his fruit, say Bramley's Seedling, from October until January, or even later, on the chance of obtaining 2s. or 4s. per bushel more than would be obtained at the time of gathering? Personally I do not think it would, as I have tested the matter. In Southampton, last October, the best price obtainable for a bushel of 48 lbs. of fruit was 6s., and in this case the sample was of the

prevailed there in Apple culture. The small fruits are used for making cider. My advice to English growers is to grow early varieties and market them before the imported fruits come to hand. *E. Molyneux.*

—It is very pleasant to again see Mr. Herrin's signature in the *Gardeners' Chronicle*: time was when it appeared frequently, but the claims of a business are inexorable. I am sorry to say I cannot give exact replies to his pertinent questions, for I am living in a temporary home and am unable to unpack my notes and books. The Apples treated as described on p. 58 comprised such sorts as Alfriston, Annie Elizabeth, Beauty of Kent, Bismarck, Dumelow's Seedling, Loddington Seedling (Stone's Apple), Lord Derby, Peasgood's Nonesuch, Striped Beefing, and Tom Putt. Such kinds as Lord Derby and Bismarck, which, under ordinary conditions, are in season at about November, were gathered, I believe, during the last half of July, whilst the later Apples were gathered about a fortnight afterwards. *A. C. Bartlett.*

LARGE ORCHID PLANTS.—The illustration of a splendidly-grown variety of *Cattleya Triana* on p. 108, affords an excellent example of the greater decorative value of Orchids when large

plants are grown. Far too often gardeners aim at increasing the number of their plants, and in the houses under their charge one sees scattered about a number of small plants which, generally speaking, have little decorative value. Last autumn, I saw in a west-country Orchid house quite a number, probably 30, small plants of *Cypripedium Spicerianum* growing in 3-inch pots. They were flowering well, and were arranged in straight lines at the edges of the stagings. The comparative rareness of the *Cypripedium* arrested attention, but had it been one of the commoner Orchids, a passing glance would suffice. But if, instead of a number of tiny plants in small pots, *Cypripedium Spicerianum* had been potted in a few goodly-sized pans and arranged in a group, what an admiration-compelling display there would have been! *B.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 14.—*Present:* Mr. E. A. Bowles, M.A., F.L.S. (in the Chair); Sir J. T. D. Llewelyn, Bart., Drs. J. A. Voelcker and O. Stapf, Messrs. A. D. Michael, J. Fraser, W. Cuthbertson, W. Hales, G. Gordon, H. J. Elwes, E. M. Holmes, A. Worsley, R. Hooper Pearson, C. T. Drury, J. Douglas, R. A. Rolfe, and F. J. Chittenden (hon. sec.).

Variation in Wheat.—Dr. J. A. VOELCKER showed grains of wheat from plants grown in pots to which had been added successively larger quantities of magnesium oxide. The examples varied much in appearance, from a plump, starchy-looking grain, where the proportion between the calcium and magnesium present in the soil was low, to a hard-looking grain, where the proportion of the two elements was nearly equal. The nitrogen content varied in the same way, so that it was much higher where the calcium and magnesium content of the soil approached equality than where the calcium content was much in excess of the magnesium. The crop also increased with the increased content of magnesium, until the ratio between calcium and magnesium reached unity. Dr. VOELCKER exhibited these specimens to illustrate the influence of the chemical composition of the soil upon the character of a variety. The experiments were carried out in triplicate, and with three different varieties, with similar results. Mr. ELWES expressed himself in agreement with Dr. VOELCKER's views as to the influence of soil and climate in changing the characters of Wheat, and said that his own experience led him to the belief that many of the supposed varieties of Wheat were not fixed, and, probably, could not be fixed.

Hymenocallis macrostephana.—Mr. H. J. ELWES showed flowers of this plant (figured in *Botanical Magazine*, t. 6456). *H. macrostephana* is reputed to be a hybrid between *Ismene calathina* and *Hymenocallis speciosa*. Both species are now included in the genus *Hymenocallis*. Mr. Hoog, of Haarlem, some time ago, repeated the cross, and raised the fine form *Hymenocallis "Daphne,"* very similar to, but finer than the original *H. macrostephana*. (See note by Mr. Worsley in *Gardeners' Chronicle*, XXIX. (1901), p. 72.)

Galanthus.—Mr. ELWES also showed a fine and vigorous form of *Galanthus*, which Mr. BOWLES thought to be of hybrid origin, and took for further examination.

Dasyliion glaucophyllum.—Mr. HOLMES showed portions of a plant of the fodder plant, to which attention was drawn by Dr. VOELCKER at a recent meeting, and which was then thought to be a species of *Hechtia*. He was now able to identify it as *Dasyliion glaucophyllum*.

Achillea millefolium var. rubra.—Mr. FRASER showed a dark-red form of *Achillea*, similar to that often grown in gardens, which he had found growing wild at Killin, Perthshire.

Polypodium vulgare var.—Mr. C. T. DRURY showed a form of a *Polypodium* very nearly approaching the beautiful variety *combiense*, which had been found growing near Barnstaple, North Devon.

Odontioda × Cr. uniana.—Mr. R. A. ROLFE showed flowers of this hybrid, raised by Messrs.

Charlesworth & Co., between *Cochlioda Noezliana* ♀, from Ecuador, and *Odontoglossum cordatum* ♂, from Mexico, and remarked upon the great differences between the parents. The hybrid was bright scarlet, like the *Cochlioda*.

Fasciated Wallflower.—Mr. E. KNOWLDIN sent from Dublin a fasciated Wallflower, which had been found growing on a wall. The specimen broadened out and forked at the top of the stem.

HORTICULTURAL CLUB. (ANNUAL DINNER.)

FEBRUARY 14.—The annual dinner was held on this date at the Hotel Windsor. The president, Sir John Llewelyn, Bart., presided, and there was a fairly good attendance of members and friends, including ladies. The tables were prettily decorated with flowers by the kindness of Messrs. Veitch.

After Sir John Llewelyn had proposed the loyal toasts, the Rev. Joseph Jacob proposed in happy terms the toast of the "Royal Horticultural Society." Mr. Harry J. Veitch responded in a speech which showed how thoroughly satisfactory the affairs of the premier horticultural society really are. Incidentally, he stated that the Council was about to form a rockery at the Wisley Gardens, and that already a sum of £1,000 had been voted for the purchase of stone and other materials for this purpose.

The president proposed the toast of "The Club," which he said intended to heartily fulfil its social functions on the occasion of the great International Horticultural Exhibition of 1912 by extending hospitality to the visitors that event would bring to our shores. Mr. Rudolph Barr responded. The toast of "The President" was proposed by Mr. Bilney, and received with all the honours. The toast of the visitors proposed by Mr. George Paul, J.P., was responded to by Mr. Chiappini, the commercial agent in this country for United South Africa. He related interesting incidents in South African life, and said that the trade between Britain and South Africa was increasing by leaps and bounds. Some figures and other details given to illustrate this latter statement caused considerable surprise and satisfaction. The speeches were interspersed with songs and instrumental music.

Previous to the dinner, the annual meeting of members took place in the club room, and a report for the year 1910 was presented by the committee. The number of members was stated to be 127, but two deaths have taken place since the report was compiled, namely, Mr. George Hobday and Mr. T. Simpson. The financial statement submitted by the hon. treasurer, Mr. Harry Veitch, showed that the accounts were satisfactory.

STIRLING AND DISTRICT HORTICULTURAL.

FEBRUARY 14.—A lecture on "Weeds, their Control and Extermination" was given before the members of this society on the above date by Professor Macalpine, of the West of Scotland Agricultural College, Glasgow. The president, Mr. Jas. Johnston, presided over a large assemblage of the members. Professor Macalpine dealt with the uses and foods of plants, and described the methods by which seeds of weeds were distributed.

WEST OF ENGLAND CHRYSANTHEMUM.

FEBRUARY 15.—The annual meeting of this Society was held at the Mutley Grammar School, Plymouth, on this date. The president, Mr. C. Bewes, occupied the chair. The society has been in existence for 21 years.

The report showed that the past year had been a successful one, there being a balance in hand of £17 4s. 6d., being double that of the previous year.

On the motion of the president, the report and balance-sheet were adopted. The president, Mr. Bewes, and the vice-presidents were re-elected. The resignation of the hon. secretary, Mr. Wilson, was accepted, and a vote of thanks was accorded him for his services during 21 years. Mr. E. Arnold was elected hon. secretary, and Mr. F. T. Bulteel hon. treasurer.

SCOTTISH HORTICULTURAL.

THE PRESIDENT'S ADDRESS.

FEBRUARY 7.—In our last issue we referred briefly to Mr. Massie's presidential address at the annual meeting of the Scottish Horticultural Association. The following extracts from the address relate to Mr. Massie's proposals in respect to the future work of the Association. The proposals were remitted to the Council for consideration:

Our aims, I hope, as an association, will rise yet higher than the reading and discussion of papers, profitable as these have been. A horticultural institute was one of our early dreams, and I see no reason why we should not have one by-and-by. It would serve as home of horticulture, where a systematic course of theoretical and technical instruction is available to all young gardeners, and where an examining body grants diplomas of fitness that would be a certain passport to all gardeners possessing them to the highest places of preferment in the profession. Why should there not be a Faculty of Gardeners, admission to which would be a certificate of fitness? It is often said that the remuneration of gardeners is, as a rule, so low that there is no encouragement to pursue higher attainments. No doubt the wages of gardeners are much too meagre for the varied services rendered and expected, but still we find the highly qualified men generally get the few prizes that are going, and I am certain that high attainments will always find some fitting reward, and many an employer would soon see it to be to his best interest to retain the services of a really qualified man, even at the cost of a considerable rise in wages. It would be a crowning success to our association to be the means of thoroughly educating and fitting gardeners for the very best positions, and also of effecting the long-wished-for improvement in remuneration. To establish such an institute might be a matter of difficulty, but difficulties only exist to be overcome, and there are brains and enterprise and energy enough amongst the members of the Scottish Horticultural Association to overcome greater difficulties than any likely to be met with here. It might be quite possible to raise the necessary funds by some such spirited movement as the carrying through of a great open-air summer carnival and floral festival. Such fêtes have already raised large sums for public objects, and no public body I know of is more capable of more successfully inaugurating and carrying through such an undertaking as ourselves. To hold our meetings, gentlemen, in our own room, its walls hung with the portraits of great horticulturists to inspire us, a well-stocked library, a thorough system of technical education going on, and young men going out into the world periodically bearing the stamp of our approval, and a thorough system of benevolence to aid the widows and orphans of gardeners or those of their number who by misfortune might come to poverty, would be indeed a consummation devoutly to be wished. This concludes my historical references to this subject, which have necessarily been full in order to show those of you whose connection with the association is of somewhat recent date that this question has from the very first been kept in the forefront among the aims and objects of the association, and to show you that what I am about to propose is no innovation, but would merely be the logical outcome of this persistent advocacy. I propose nothing new to you except that you should exchange a philosophy of words for one of deeds and actions.

FIRST CHRYSANTHEMUM SHOW IN WAVERLEY MARKET.

It is now 19 years since Mr. Welsh referred to the formation of a gardeners' institute as being almost within our reach. Three years before that, in 1889, the association had commenced to hold its Chrysanthemum shows in the Waverley Market, and, owing to the great success with which these were attended, it may be that the office bearers and members alike became so obsessed with them that the greater question was completely lost sight of, at any rate, with the exception of the allusion to it by Mr. Todd in his address 14 years ago, no further reference to it is to be found until four years ago, when it was resuscitated by one of my immediate predecessors in this chair, Mr. D. W. Thomson, who, in his

presidential address, strongly urged the formation of a great horticultural centre for Scotland in this city, and at the present moment an undischarged motion by our friend Mr. King to make a commencement by raising a fund for the purpose stands in our council minutes.

Ex nihilo nihil fit is a classical phrase as trite as it is true. Out of nothing nothing can come, and unless we cease our talk and begin to act we shall be no further forward in the next decade than we were in the last, or than we are to-day, if, indeed, we have not retrogressed. Times have changed. There is no reasonable prospect at present or a return to the palmy days of Chrysanthemum shows of 5 to 20 years ago. There is small prospect at present, even with the greatest attractions we can legitimately offer, of drawing £1,200 at the gates, nor of any sum approaching it. In 1908 and 1909 we had a heavy loss. Last year, with a somewhat novel departure in our show-procedure, we scraped through with a small surplus, but it was only accomplished by exercising the most rigid economy. The unpleasant fact has to be faced that there is at present a steady decline in the attendances at our shows, and we have no assurance that the decline will not go on. The question then, comes to be, how far can we go in this direction? There must be a limit to our economy if there is none to the smallness of our attendances, and if the decline in the latter goes on, what then? I sincerely hope we have reached bed-rock in our attendances, but who can tell? Counter attractions, which 10 years ago had no existence, have sprung up—and are still springing up—in all directions. The best military bands can be heard elsewhere in the city almost any season. The Waverley Market, when compared with other up-to-date halls for entertainments, has earned an unenviable notoriety as a kind of refrigerator in the month of November, a fact which cannot be too strongly impressed on the Corporation, to whom the building is a source of very large revenue, most of which is derived from rents for shows and other entertainments. Times are bad, and, above all, in spite of the huge efforts which are being made by educational authorities to raise them to a higher level intellectually than they ever had an opportunity of rising to before, there seems, generally speaking, a strong desire on the part of our youth for less intellectual forms of enjoyment than was formerly the case. Flower shows have ceased to attract as they used to do, and as the holding of them was not part of the original work of this association, I think we should pause and reconsider the whole question afresh. As I have said, we cannot hope for an immediate return at present of the palmy days of our Chrysanthemum shows of 20 or even 5 years ago. Our funds are not increasing, but our association is growing, and its work is increasing. But restricted revenue will strangle its efforts to expand. How, then, are we to exist? For years the revenue of the association has not met its expenditure, and the deficit has had to be made up out of show surpluses. But if these, too, are to cease, how is the work to be carried on? It seems to me that we must move, and move at once.

PUBLIC LIBRARIES. BOTANICAL MUSEUM. SECTIONAL LIBRARIES WANTED. HORTICULTURAL INSTITUTION. JOURNAL. TRANSACTIONS.

I have already given you a résumé of what has been done since the starting of the association with regard to a library, museum, and reading room, the acquirement of which, according to its original constitution, was one of its principal objects. In the matter of libraries, there has been a great change since the association was formed, and we have now in Edinburgh, and many of our other towns, thanks to the munificence of our honoured countryman, Mr. Carnegie, excellent public libraries. In this city, too, we have a museum in connection with the Royal Botanic Garden, and a very excellent botanical collection is now housed in the Royal Scottish Museum, and as the latter institution is open on certain evenings, this collection, being more accessible is, perhaps, of even greater value to the working gardener than that of the former institution. So far as we are concerned, the formation of a museum seems now not to be so necessary as it formerly was—if it is necessary at all—but it is otherwise with a library. The public libraries are intended chiefly to supply the wants of the great general reading public, and for purposes of reference; but sec-

tional libraries, it seems to me, in these days of technical training, are more urgently required than ever, for the literature on specific subjects is vast compared with what it used to be. One could not expect to find in, say, the Edinburgh Public Library all the weekly and monthly and other horticultural papers and magazines, but that is what our young men require, and it goes without saying that a reading room is necessary where such literature is provided. This then was what was aimed at in the original constitution. In the revised constitution of 1908, the words "Horticultural Institution" are used, and this embraces all that was stipulated for in the original constitution, and more if necessary. As for the starting of a journal, this, I think, however much the want might be felt at the time the demand was made for it, is in these days unnecessary. But there is no reason why our transactions should not be improved, more especially as they are the only medium by which members living in the distant parts of the country are kept in touch with the centre. Not only should they contain reports of the papers read at the meetings, and of the proceedings, but they should be made a medium of reference to papers, &c., of outstanding importance published elsewhere, so that the members may know where to lay their hands on what they want.

FINANCES OF ASSOCIATION. FLOWER SHOW FINANCE. SUBSCRIPTIONS.

Having said so much about the attainment of one of its objects, I now wish to glance at the financial working of the association. As I have already mentioned, the ordinary revenue of the association does not meet its expenditure, and any deficit there is has to be made up out of flower show surpluses. But if there is a loss on the show, as there was in 1908 and 1909, it means that this, plus the deficit on the association account, has to be taken out of the funds. Now this, I think you will admit, is not only unsatisfactory—it is very bad finance. The association ought to, and must, be self-supporting if it is to go on progressing. It should be quite independent of show surpluses, and, of course, it follows that it should not be involved in losses on the show. How is this to be done? Well, I think that show surpluses should be carried to a reserve fund to provide against losses on the show when these occur, and the revenue of the association from members' subscriptions and interest on its investments should be so adjusted as to cover its expenditure. But it is quite apparent to me that it is impossible to make ends meet in the association account on the present basis of a £2 2s. life membership subscription and an ordinary annual subscription of 2s. 6d. At the rate of interest we at present receive on our invested funds (and it is likely to decrease when we realise the major portion of our stocks and invest them in Trust securities), we are getting about 1s. 6d. yearly out of every life member's subscription, and out of this we are paying 1s. in actual cash for the publications they receive and the postage of them, leaving 6d. as the price of the season ticket which they get for the show and to help to cover the working expenses of the association. We are in a little better position as regards the ordinary members, for, allowing the same out-of-pocket expenses in their case (it is a little more), there remains 1s. 6d. as the price of the show ticket, and the covering of the working expenses of the association, but this is too favourable a statement of the case, for it takes no account of expense connected with members who fall into arrear, which has to be met. According to our method of accounting, the show is not credited with any portion of the interest on the life members' subscriptions, or of the ordinary members' annual subscriptions as the price of admission; if it were, how long would it take to exhaust the life members' subscriptions? And where would the revenue from ordinary subscriptions in the association account be? I put the question to any business man present, is this good finance? Now, my proposal—there is nothing alarming about it—is that there should be a graduated scale from, say, £2 2s. downwards to 2s. 6d. in the annual subscriptions, but that none but under gardeners or other horticultural employees should be admitted at the lowest figure. I recognise, however, that it might be somewhat unfair to compulsorily raise the subscription in the case of the present members, and I would suggest that they should have the option to continue on the present basis, but that anyone resigning or lapsing would be

required to pay on the new scale on rejoining. Only in this way do I think it possible to put the finances of the association on a sound basis, and I appeal to you to give the matter your earnest consideration in the best interests of the association, the welfare of which I am sure you all have at heart.

YOUNGER MEMBERS OF THE ASSOCIATION.

There is another aspect of our work, which, I think, does not receive sufficient attention from us, and that is our interest in the younger members of the association. The young members do not, as it seems to me, take a large enough share in the work. It is to them that we must look to carry on the work of the association after those of us who are now in the sear and yellow leaf have fallen out of its ranks, and I think they should lose no time in buckling on their armour and entering the lists. About a dozen years or so ago, there was in existence in connection with this association what was called the "Junior Horticultural Association." This was composed of young men who were members of our association, who formed themselves into this body for the purpose of reading papers and conducting debates, and the association lasted for several years. I do not advocate the reformation of such a body, but I do think that the young members should have more consideration at our hands, and in order to give them facilities for the reading of short papers, the council have, at my suggestion, arranged to give up the April meeting this session to their exclusive use, and I appeal to them to come forward and take their legitimate share in the work. Many sermons have been delivered to the youth from this chair. I do not propose to preach at them, but I do invite—may, urge—they to take a fuller advantage of our meetings in training themselves to giving intelligent reasons for the faith that is in them. In order to give a stimulus to the project, I may say that the council have arranged to offer prizes in books to those who acquit themselves most creditably at the April meeting.

TEACHING OF HORTICULTURE. EXAMINATIONS FOR CERTIFICATES.

As regards the teaching of horticulture, which is referred to in some of the past president's addresses, from which I have quoted as a thing which this association should take a part in, I am of opinion that, while we no doubt should keep a watchful eye on what is being done in the matter, we should have no active hand in it. The time for this association taking up teaching as part of its work has gone past. We have now an Agricultural College in Edinburgh in which horticulture is taught by an efficient staff, and it would only be waste to overlap the work of the college in any way. But there is one thing in connection with the teaching of horticulture in which it seems to me this association might be of use to young gardeners. The time is not far distant, we hope, when the Edinburgh and East of Scotland College of Agriculture, to the governors of which your council have already made a representation on the subject (which has been courteously responded to), will institute a diploma in horticulture, and this will meet the case of all those who have the time and the means to go through a prescribed curriculum of study in the college; but there are many working gardeners who have neither the time nor the means to attend prescribed courses of lectures in the colleges, and who must, perforce, pick up their technical knowledge in any haphazard way they can, to whom some hallmark would be valuable, and it is in such cases as these that this association might be of some service by granting to them certificates of proficiency. This, of course, would involve an examination by competent examiners in the theory and practice of horticulture, but it would in no way overlap or interfere with the work of the colleges; it would, in fact, benefit them, for many of these young men would be induced thereby to take advantage of the evening classes in these institutions, and this association might also materially assist in this by granting small bursaries to deserving young men so as to enable them to take advantage of these classes. By instituting lectures on horticulture and allied subjects, this association has done a great deal for the technical training of gardeners in the past, and it would not be at all inappropriate were it now to take up this question of granting certificates such as I have described.

BENEVOLENT FUND.

There is one other matter to which I wish to refer before I close, and it is one which, I think, deserves your serious consideration; and, like some of the other subjects I have touched upon, I find it has not escaped the attention of some of my predecessors in this chair. It is the question of aiding the widow and the fatherless, and those who, through no fault of their own, have met with misfortune amongst the gardening fraternity. I am not prepared now to go into the details of such a scheme, for it would require a great deal of careful thought and consideration before it could be launched, but I for one feel that it is a scheme which should be faced, and I am sure that if it were gone about in the proper way it would succeed. I have frequently noted a generous spirit amongst you in the voting of doles from the association funds for various benevolent purposes, but I am strongly of opinion that these contributions should come direct from the pockets which we individually control. We have, of course, great charities like the Gardeners' Royal Benevolent Institution, and the Royal Gardeners' Orphan Fund, both of which are doing splendid work, but the sphere of the former is restricted to the relief of aged, distressed and disabled gardeners and others and their necessitous widows, and that of the latter to the relief of the orphans of gardeners and others. In the case of the Gardeners' Royal Benevolent Institution, the only persons who are eligible for the pension are those who have been head gardeners or their foremen, market-gardeners, market-growers, nurserymen and seedsmen, and foremen of nurserymen and seedsmen, and the widows of such persons. To be eligible, gardeners must have served in the capacity of head gardeners or their foremen in the establishments of ladies or gentlemen for 30 years, and the foremen to nurserymen and seedsmen must have served as such for the same number of years. Market-gardeners must have cultivated not less than five acres of land for 30 years, and market-growers, nurserymen and seedsmen must have been regularly engaged in the business for thirty years. Further, unless totally incapacitated through accident or incurable disease, no person is eligible for the pension under 60 years of age. No provision is made for the relief of distress in the case of the large army of younger gardeners and their widows in this charity. In the case of the Royal Gardeners' Orphan Fund, the beneficiaries must be the orphans of gardeners, foremen in gardens, or managers or departmental foremen in nursery or seed establishments. We have also in operation now a State Old Age Pension Scheme, but as no one is eligible under this till he or she is 70 years of age, it, like the Gardeners' Royal Benevolent Institution, of course, does nothing for the young or middle-aged who may require pecuniary assistance to tide them over a period of distress. Such a fund as would aid the journeyman gardener and those dependent upon him when misfortune overtakes him in early or middle life, is a desideratum, and I think we should make an effort to have a benevolent fund of this sort instituted for Scotland.

[The summary of Mr. Massie's proposals was published in our last issue, p. 110.—Eds.]

NATIONAL FRUIT-GROWERS' FEDERATION.

FEBRUARY 15.—The annual meeting of the above association was held on this date in the Royal Horticultural Hall, Vincent Square, Westminster.

Mr. C. S. Martin, the president, stated that eight important societies had been affiliated to the Federation. The Council had, he said, been able to do a great deal of good in influencing the railway companies to prevent the pilferages of which complaint had been made, and he was convinced that a meeting with the representatives of the companies as business men would bring about better results in the interests of the trade than any legislation. The Council was considering the establishment of a standard for Apple boxes, to enable British growers to compete with foreign produce which, to a great extent, held the market. The balance-sheet showed a deficit, towards the wiping off of which they had received some donations, and he reminded the members that the more the Council had to do the more they had to spend. The report was adopted.

Professor E. S. Salmon read a paper on "Lime

Sulphur Washes for Use on Foliage," describing various experiments for determining the effect of these washes on various fruit trees.

Dr. W. Goodwin dealt with "Soil Analysis and its Use to Fruit-growers," advocating mechanical as distinguished from chemical analysis, for the purpose of determining the texture of the soil and the size of its particles.

Mr. J. E. Newman described some experiments in "Electricity as Applied to Agriculture," and Mr. W. Masters, a member of the Evesham Growers' Association, read a paper on "Market Growers and Trade Protection."

SOUTHERN COUNTIES GARDENERS (SCOTLAND).

FEBRUARY 16.—The first annual dinner of the Association was held in the King's Arms Hotel, Dumfries, on this date, and was a great success; more than 50 being present. The chairman, Mr. T. Young, C.R.I., Dumfries, gave a short address on the objects of the association, and it was decided to hold a general meeting on March 4 for the purpose of appointing a committee. The proceedings included a musical programme.

IRISH GARDENERS' ASSOCIATION AND BENEVOLENT.

This society was established in 1895 as a horticultural association. Subsequently it was considered advisable to enlarge its scope of usefulness, and in 1897 it was converted (under the Friendly Society Act) into a Benefit and Mutual Improvement Society.

Monthly meetings are held in the Society's rooms, when papers on practical gardening subjects are discussed, and occasional excursions to gardens of interest are also organised.

The annual report shows that the membership continues to grow. The past year's balance-sheet shows a marked increase on the credit side, due principally to an item of £52 contributed by the seed and nursery trade.

Some two years ago a special committee was appointed to draft new rules for the better guidance and working of the association. The results of their deliberations were confirmed at a special general meeting called for the purpose. These rules have since been duly registered under the Friendly Society's Act, and copies have been circulated among the members.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 22.

Forty-one days with less than three-quarters of an inch of rain.—This proved a warm week for the time of year. On the two warmest days the temperature in the thermometer screen rose respectively to 55° and 54°, making these the two warmest days as yet of the present year. On the warmest night the exposed thermometer did not fall lower than 45°, which is an exceptionally high minimum reading for the month. The ground is now getting warmer, and is at the present time 1° warmer at 2 feet deep, and 4° warmer at 1 foot deep than is reasonable. Rain fell on four days, but to the total depth of only one-third of an inch. The present dry period has now lasted 41 days, during which less than three-quarters of an inch of rain has been deposited. We have to go back to January and February, 1909, in order to find any consecutive 41 days as dry. But what makes this dry period so remarkable is that it has followed immediately a similar number of days which were as persistently wet. For the first time for nearly 5 weeks there was to-day some measurable percolation through both of the soil gauges. The sun shone on an average for 3 hours, 10 minutes a day, or for half-an-hour a day longer than is usual at the same period in February. The winds continued high throughout the greater part of the week, and in the windiest hour the mean velocity reached 21 miles—direction W.S.W. For the last 11 days the wind has come exclusively from some southerly or westerly point of the compass. The mean amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by five per cent. E. M., Berkhamsted, February 22, 1911.

SCHEDULES RECEIVED.

Clevedon Horticultural Society's 35th annual flower show, to be held in the Clevedon Hall Paddock, on Tuesday and Wednesday, August 8, 9. Hon. secretary, Mr. F. Seckington, Seavale Road, Clevedon.

Lymington Horticultural Society's annual exhibition, to be held in the Public Hall, Lymington, on Saturday, August 26. Secretary, Mr. T. Hamilton, Schoolhouse, Lymington.

Knaresborough and District Horticultural Society's show, to be held in the grounds of Convingham Hall, on Tuesday, August 8. Secretary, Mr. Wm. Gelder, Hambleton View, Knaresborough.

MARKETS.

COVENT GARDEN, February 22.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Eds.]

REMARKS.—The Grape trade shows a decided improvement all round. Imported Apples are fairly plentiful, and the best samples are realising good prices. English Apples are limited to Dumelow's Seedling (Wellington), Bramley's Seedling, and Newton Wonder; these also are selling well. A consignment of Cape fruit, per s.s. "Kildonan Castle," received this week, amounted to 10,000 cases, consisting of Peaches, Pears, Plums, Nectarines, Melons, White and Black Grapes and about 150 boxes of well-coloured, kidney-shaped Mangos of first-rate quality. Strawberries are being sent from the Worthing district in increasing quantities. The berries are of much finer quality and appearance than earlier ones. Tenerife Tomatoes are arriving in larger consignments, and prices are lower than those of last week; the quality of the berries is very good. The supply of Mushrooms is in excess of the demand. Broad Beans and Peas are a limited supply, and are realising high prices. Ordinary vegetables continue to sell well. Trade generally is firm in all departments. E. H. R., Covent Garden, February 22, 1911.

REMARKS.—Trade still keeps very steady, and prices have not altered. Stocks of tubers in London are very heavy, and there are no prospects of obtaining higher prices at present. Edward J. Newborn, Covent Garden and St. Pancras, February 22, 1911.

Obituary.

CHARLES FOSTER.—It is with great regret that we record the death of Mr. Charles Foster, director of the Times Experimental Station, at Sutton Green, near Guildford. Mr. Foster, who had been seriously ill for some months, died on the 16th inst., at the early age of 43. He was born in Lincolnshire, where his father is still in business. Early in his career he was employed in the celebrated gardens belonging to the late Mr. A. H. Smee, at Hackbridge, in Surrey, at the time when Mr. G. W. Cummings

THE LATE CHARLES FOSTER.

was head gardener there. On leaving Hackbridge, he was appointed head gardener at Dolwais, in South Wales. There he laboured strenuously and successfully until his appointment to the charge of the gardens at Aberpergwm, Glyn Neath. Though a most beautiful place, the gardens of Aberpergwm were scarcely in a condition at the time of his appointment to satisfy Mr. Foster. He entered into the task of remodelling the grounds with characteristic zeal and energy. The present writer remembers visiting him at Aberpergwm, when Mr. Foster was frequently to be found in the gardens at 4 a.m. in the morning, and till dusk in the evening. His great industry and capacity soon received their reward. Although still under 30 years of age, and having only the facilities afforded by a small garden, Foster, nevertheless, ventured forth to meet in competition the most successful vegetable exhibitors at the Shrewsbury Show, and at the exhibitions at Cardiff, Chester, and other places. When he was successful at these shows, it was such men as Edwin Beckett, William Fife, and William Pope whom he excelled; and they were among the first to congratulate him and to urge him to further efforts. His fame as a gardener spread

far and wide, and Foster of Aberpergwm became a name of weight in the horticultural world. After a little time he was called upon to take a more important charge, that of Doddington Hall Gardens, near Lincoln. Here, again, Foster made remarkable improvements, whilst his untiring energy became more and more known amongst gardeners. Later, he was appointed as gardener to the Earl of Stradbroke, Henham Hall, Suffolk. He was as successful at Henham as he had been elsewhere. Under his care the gardens became in every way a model of first-class culture and cleanliness. Indoors and out-of-doors, in the fruit, vegetable, and flower departments, there was evidence of the most skilful management. At Henham, Foster closed his career as a private gardener, relinquishing his post to superintend the gardens attached to the new horticultural department of the University College, Reading. His duties in this post consisted not only in managing the College gardens, but also in lecturing on horticulture to the students of the department. It was during his Reading period that Mr. Foster achieved his greatest success. Those who were present at the formal opening of the horticultural department of the College a few years since, will remember the extraordinary crops of Tomatoes and Cucumbers in the span-roofed houses on that occasion, and the wonderful fruitfulness and heavy cropping observable both indoors and in the out-door vegetable garden. As soon as he had organised his teaching work, and developed the resources of the College garden, Foster commenced to exhibit vegetables and other horticultural produce at the Royal Horticultural Society's meetings in London. As a consequence of the excellence of these exhibits, he came to be looked upon as one of the foremost cultivators in the country. His strenuous labours on behalf of the horticultural department of University College, Reading, were appreciated by the council of that institution, and won for him the position of assistant director of horticulture. In 1909 Foster left Reading to take up a position under Lord Northcliffe, who had decided to convert a Wheat field on his Surrey estate, at Sutton, into what is now known as the Times Experimental Station. On the occasion of his leaving Reading he was the recipient of the well-deserved honour of election to the associateship of University College. Mr. Foster's task at Sutton was an uphill one. There was much rough work to be done. Nevertheless, in an incredibly short space of time the Wheat field came to present the appearance of a cultivated garden, and those who had not visited the place since he commenced operations there were startled to see Foster coming to the R.H.S. meetings with marvellous vegetables from the newly-developed Experimental Station. Though never an enthusiastic advocate of what is termed "French gardening," he was in every sense of the word an intensive cultivator, and his work at Sutton was a splendid demonstration of the methods best adapted for small holdings and market-gardens. Foster took an immense interest in Sweet Peas. He was a member of the Executive and Floral Committees of the National Sweet Pea Society, and his trials in the grounds of the college at Reading produced results equal to the best to be seen at the exhibitions. Hence, when the National Sweet Pea Society commenced to institute comparative trials of varieties, Foster was asked to conduct them in the Reading University grounds. In this case, as in every other direction, the college authorities encouraged Foster in his work, and afforded him every facility for carrying out this important work; with what results may be seen in the reports these trials attained. On his removal to Sutton, the Society requested Foster to continue the trials there. This he did, and also provided facilities for the newly-formed Vegetable Society, on the committee of which he served, to conduct trials of vegetable seeds on the Sutton ground. In addition to these manifold activities, Foster found time to act as a member of the Fruit and Vegetable Committee of the Royal Horticultural Society, and he was a past chairman of the Council of the British Gardeners' Association. He was a frequent judge at horticultural shows. Mr. Foster leaves a widow and two sons. Mrs. Foster and the younger son (who is a student at Wisley) remain in their present

home by the express desire of Lord and Lady Northcliffe. The funeral took place at Old Woking cemetery on Monday last, when a large gathering of representative horticulturists were present. A number of floral wreaths were sent, and amongst them tokens of sympathy from the Reading University College, the National Sweet Pea and National Vegetable Societies, British Gardeners' Association, Messrs. Sutton & Sons, and others. Mr. Foster was remarkable not only for his strenuousness and extraordinary efficiency, but also for an almost intuitive knowledge of the habits and requirements of plants. Under his masterly and persuasive care, all plants flourished, obedient to the magic of his method. He was a man of genial disposition and possessed of great personal charm.

GEORGE DANIELS.—By the death of Mr. George Daniels on the 10th inst., East Anglian horticulture loses one who took a very prominent part in the last decades of the past century. One of the founders of Daniel Brothers, seed-men, of Norwich, he was also an enthusiastic supporter of the local horticultural society, and was one of the promoters of the East Anglian Horticultural Club. For some years past he had ceased to take an active in-

THE LATE GEORGE DANIELS.

terest in public affairs, owing to advanced age, and for the same reason he retired from the firm of Daniel Brothers when this business was converted into a limited liability company. Many of our older readers in the east of England will recognise in the portrait which we reproduce the familiar figure of one whose name will be held in esteem for his untiring efforts to spread a love of horticultural pursuits.

DEBATING SOCIETIES.

ELSTREE AND BOREHAM WOOD HORTICULTURAL.—A lecture on "Hardy and Half-hardy Annuals" was delivered before the members of this association on Tuesday, the 14th inst., in the Church Room, at Elstree, by Mr. Townsend, of Messrs. Sutton & Sons, Reading. Mr. COX, of the same firm, gave a series of lantern slides, illustrating Mr. Townsend's remarks. There was a large audience present, and great interest was evinced in the lecturer's remarks, and also the many excellent coloured and other slides. Thirteen new members were elected.

READING GARDENERS'.—The annual tea and entertainment in connection with this association, took place at the Abbey Hall, on Wednesday, the 15th inst. About 100 members and friends were present to tea, and later between 700 and 800 assembled for the entertainment.

CHELMSFORD GARDENERS'.—The weekly meeting was held at the County Laboratories, on Friday, February 17, when Mr. J. Seabrooke, of Chelmsford, read a paper on "Insect Pests." Mr. G. Stewart occupied the chair. Mr. Seabrooke gave the following methods for destroying insect pests:—By poisoning, by destructive fluids sprayed on the insects, by fumigating or vaporising, and mechanical contrivances, such as grease bands. Winter washes were described as the best preventive methods.

CROYDON & DISTRICT HORTICULTURAL.—The eleventh annual dinner was held on February 15, at the Greyhound Hotel, Croydon. The Mayor of Croydon, in proposing the toast of the society, speaking as the head of the municipality, said they realised that it was their duty to further every beneficial object in the borough, and that was the reason why he was there that evening. Dr. Jackson, who replied, said that the society was doing excellent work, and he congratulated the president on the attendances at the fortnightly meetings. The membership was greater than at any period of the society's history.

WATFORD AMATEURS' & GARDENERS'.—At the meeting of this society, held on February 10, a lecture on "Insect Pests" was given by Mr. A. S. Brooks, of Aldenham House Gardens, Elstree. The lecture was illustrated by lantern slides.

CHESTER PAXTON.—At the meeting of this society, held on February 18, Mr. G. Atkins, of Erding Park Gardens, Wrexham, delivered a lecture on "The First Principles of Fruit Growing." Mr. N. F. Barnes presided. The lecturer dealt with his subject, which was chiefly in relation to Apples and Pears, under the following heads: choice and preparation of soil, varieties, planting, aspect and shelter, pruning, feeding, spraying, and fruits on walls.

GARDENING APPOINTMENTS.

Mr. W. WALKER, for the past 5 years at Criche Gardens, Wimborne, Dorset, as Gardener to Mr. SHENLEY, Warsash, Southampton.
Mr. F. T. HURFORD, late Gardener at Becton Hall, Neatishead, near Norwich, as Gardener to HENRY LEWIS, Esq., Walsingham Abbey, Norfolk.
Mr. ERNEST P. PANNELL, formerly Foreman at Gosfield Hall Gardens, Halstead, Essex, and recently Gardener to H. FERENS, Esq., The Bounds, Hernhill, as Gardener to Wm. C. DAWES, Esq., Mount Ephraim, Hernhill, Faversham, Kent.
Mr. R. JAMES, late Gardener to SAMUEL BAMFORD, Esq., Hawthornden Manor, Uttoxeter, and previously Foreman at Wroxton Abbey, as Gardener to Lord NORTH, Wroxton Abbey, Banbury.
Mr. JAMES MCNERLIN, as Superintendent at King's Heath Park, King's Heath, near Birmingham.

ANSWERS TO CORRESPONDENTS.

BAMBOOS FOR LEICESTERSHIRE: *Arundo.* Success with Bamboos depends largely upon a careful choice of position. They will not succeed in places exposed to north and east winds, but if the plants are provided with good shelter from those quarters, the following Bamboos would be likely to do well in your neighbourhood, for we have seen very good Bamboos in Leicestershire: *Arundinaria japonica* (Bambusa Metake), *A. nitida*, *A. fastuosa*, *Phyllostachys viridi-glaucescens*, *P. nigra*, and *P. Henonis*. You might try these six sorts and watch the results. In any case you must expect the plants to present a certain amount of shabbiness in spring. The great charm of Bamboos is their beauty in autumn and winter. The *Arundo* is not likely to succeed anything like so well as Bamboos, and it is very apt in cold districts to die out in a year or two. The ground should be well trenched before planting Bamboos.

BOOK ON THE HOLLY: *Dea. Holly, Yew, and Box* by W. Dallimore. You will find the other particulars you require in this work. It may be obtained from our publishing department, price 8s., free by post.

CAMELIAS: *A.P.* The dropping of the flower-buds before they are expanded is a common trouble in the cultivation of the Camellia. It is usually due to dryness at the roots and in the atmosphere. When the plants are grown in pots, the roots often become matted together,

compressing the earth, so that when water is applied it does not thoroughly moisten all the soil.

CLIMBING ROSES: *Furze-Bush.* Mme. Alfred Carriere, Reine Olga de Wurtemberg and Ards Rover are three varieties which have a long season of bloom. Such ramblers as Dorothy Perkins, White Dorothy, and most of the hybrid Wichuraiana Roses make a grand show over a very large space, but their season of bloom is a short one. The most effectual way to prevent bare spaces at the bottom of the walls is to plant free but compact growers such as Marie Van Houtte and Anna Olivier between the stronger-growing varieties. We would recommend 10 tall plants upon each wall with the dwarfier varieties between them.

CÆLOGYNE CRISTATA: *M. L.* A plant of *Cælogyne cristata* bearing 1,400 blooms formed the subject of the Supplementary Illustration in the issue for January 15, 1910. We shall be pleased to receive the photograph of your specimen for inspection.

CORRECTION.—In the review entitled *A New Work on British Forestry* (see p. 99), the last paragraph but one should have been enclosed in brackets and initialled "Eds."

FIG LEAVES WITH MARKINGS: *D. H. L.* No disease is present; the markings are apparently the result of scorching.

GRAPE-GROWING IN AUSTRALIA: *H. E. K.* We are informed that there is plenty of opportunity for Grape-growing in Australia, principally in the Southern parts. Write to the Agent-Generals for New South Wales, 123, Cannon Street; Queensland, 409, Strand; Victoria, Melbourne Place, Strand; and Western Australia, 13, Victoria Street, London, for particulars.

NAMES OF FRUITS: *Myhill.* Dredge's Fame.

NAMES OF PLANTS: *J. G.* You have sent more than the proper number. 1, *Cyperus alternifolius*; 2, *Carex brumnea variegata*; 3, *C. sp.*; 4, *Ophiopogon Jaburan variegatus*; 5, *Curculigo orchadioides*; 6, *Rhapis flabelliformis*; 7, *Maranta sp.*; 8, *Selaginella Braunii*; 9, *Adiantum cultratum*; 10, *Justicia magnifica*; 11, *Asplenium bulbiferum var.*; 12, *Maranta bicolor.* The remainder next week.—*W. H. H.* 1, *Epimedium rubrum*; 2, *Aucuba japonica var.*; 3, *Daphne Mezereum*.—*R. P.* 1, *Dracena Sanderiana*; 2, *Cordyline obtecta*; 3, and 4, *C. stricta*.—*M. S., Morpeth.* *Hamamelis japonica* (arborea).—*J. S.* 1, *Garrya elliptica*; 2, *Berberis stenophylla*; 3, *B. Darwinii*; 4, *Cotoneaster horizontalis*.

PARCEL LOST IN THE POST.—We have received from the Returned Letter Office a label detached from some parcel addressed to the Editor, and bearing the Tunbridge Wells postmark of February 10.

PEACH BUDS DROPPING: *S. C., Colworth.* The dropping of the buds of Peach trees is usually caused by some check or by overcropping. The most frequent cause is keeping the borders too dry in the autumn, when the trees are ripening their shoots. But it must be remembered that excess of moisture at that stage will also set up bud-dropping. Some varieties of Peaches are more prone to drop their buds than others.

RAISING SEEDLINGS OF ASTER CORDIFOLIUS AND A. ERICOIDES: *Bippo.* Sow the seeds when they are ripe in the autumn in well-drained, shallow pans or boxes, filled with a light, sandy compost. Germinate them in a gentle heat, and prick off the seedlings when the second leaf has formed. Frequently the seeds remain dormant for five or six months, so that patience must be exercised. It is very seldom that the best varieties of these Asters come true from seed.

ROSE DISEASE: *A. Boulder.* The markings on the leaves are caused by a fungus—*Peronospora sparsa*. Dust the plants with flowers of sulphur when the foliage is damp, and be careful to apply it to the under surface of the leaves.

THE PRUNING OF ROSES.

SPRING is upon us, and we Rose-growers are turning our thoughts to a fresh pruning season and the final training of our Roses. We have finished cutting down the stocks budded last summer, which always seems, as it were, to introduce us to the pruning season, and we are looking round for a fresh task. "Never prune until you know what kind of Rose you are dealing with" is the first rule in pruning, and placed by Mons. Viviani Morel at the head of his *Pruner's Alphabet*.

We generally start with the Rugosas, and for these the usual direction given is to "go as you please," i.e. whether you prune severely or lightly does not much matter. But this is not quite correct, for we have now three distinct types of Rugosa, requiring different consideration in pruning.

First, there is the old-fashioned Rugosa, which will give us the well-known, beautiful red berries in autumn. Calocarpa, Delicata and the charming Blanc Double de Coubert, which last will give us flowers and fruit on the plant at the same time, are examples of this type. It is true that we may prune them either hard back or devote most of our attention to thinning and tying, but we shall get very different results, according to which method we employ. The system of hard pruning will give us flowers, but they will be late, and one of the chief points of the Rugosa is its earliness, so unless we do not want early flowers and are cramped for space, it is best to make use of the second method and thin out the old wood, confining the pruning, properly so called, to such slight shortening of the shoots as the plant may require for the sake of shapeliness.

I assume, as a matter of course, that an old plant is being dealt with, for there is

another rule of pruning which scarcely admits of an exception, viz., that every Rose planted the previous autumn must be cut hard back, regardless of the result in the first year. I had a remarkable illustration of the application of this rule last year. I had sent me in the previous autumn a Multiflora x Wichuraiana hybrid that was new to my garden. Now, Roses of this class make roots very quickly and sometimes form the exception that proves the rule, and, wishing to see the flowers, I merely cut back the tops of the shoots a little and put them in as cuttings. At the end of the season I found the cuttings had given me more vigorous growth than I had obtained from the rooted plant. Nevertheless, I will confess that, while I admit the rigidity of the rule, it is one which, in the case of new climbers, I find hardest to bring myself to carry into effect.

To return to our Rugosas. The second group contains those of the Conrad F. Meyer type, great, strong growers with very thorny stems. These do not give us any choice of method, for they should have very little pruning at all. We should confine our operations to merely removing damaged wood and thinning out that of two years and upwards. When, however, it is possible to do so, some at least of the branches should be bent and tied down, either permanently or till the buds towards the base have started. The fault of the Roses in this group is that they are not naturally very free flowering, so everything should be done to induce them to shoot from the whole length of the stem, otherwise the crop of flowers will be small. So far as I can judge, the new yellow Rugosa, "Daniel Lesueur," which seems very nearly related to the Dijon Teas, should be treated in the same way as those of this group.

The third group is a small one, not, perhaps, very generally grown as yet, and of decidedly less vigour than either of the preceding groups. Probably its members contain a greater proportion of Tea-Rose blood in their composition. With regard to these, I think the nearer they approach in character to the Tea or Hybrid-Tea the harder they should be pruned.

THE HYBRID PERPETUALS.

These next claim consideration, and at the outset we are met with two distinct schools, which may be said to be headed respectively by our two most successful amateur exhibitors. They may conveniently be called the early and late schools. The followers of the early school begin to prune in February, finish early in March and cut right back to one or two eyes, with a view to encourage the plant to break from dormant buds at the junction of the Rose with the stock, though a few varieties, such as Charles Lefebvre, are left with somewhat longer stems. This school of rosarians holds that early pruning is preferable on four grounds: (1) The buds which are left to develop are in a very backward condition and are not suddenly forced into growth, but permitted by the early period at which they are called on to take the sap from the roots to develop slowly and gradually, and it is thought

they are thereby able to produce better-shaped flowers than if pruning is deferred till the sap is in full flow, for, if this course were pursued, these backward buds would suddenly be called upon to make use of the full flow of the spring sap. (2) The plants suffer less from bleeding. (3) The operator has a greater choice of weather. (4) The severe pruning and constant supply of young wood keep the plants healthy. The late school, on the other hand, prefers to leave pruning of the H.P.s till the third week in March, and does not advise so severe a pruning, even for exhibition Roses, leaving from 2 inches to 6 inches of old wood, say from three to five buds, or even more in the case of the strong-growing varieties such as the Duke of Edinburgh or Hugh Dickson. The advocates of late pruning think that by this practice they run less risk from frost, which may injure the buds just as they are starting to grow, and cause them to produce malformed flowers; further, that the new growth "gets away" quicker, and that rapid development is better than slow growth.

Where doctors differ who shall decide? Personally, I feel no difficulty, because I have little choice. It is almost a matter of necessity to get the H.P.s attended to as soon as possible, in order to leave time to deal with the rest of the Roses before other garden work demands attention. Whatever method is chosen, I think the rule for pruning H.P.s must be "the earlier the harder."

Where the plants are not required to produce flowers for exhibition or for specimen vases, but for the decoration of the garden, it is usual to find a direction to prune more lightly, some advising that a foot or more of last year's wood be left intact. This may be necessary where the object in view is to form a specimen bush, but I think the H.P. is hardly the most suitable Rose to grow for that purpose, and, in spite of the great preponderance of authority in favour of this view, I hold the method of treatment to be wrong, or at least undesirable. Where a larger number of flowers from the individual plants are required, resort should be had to "pegging down." This is an admirable method of growing the stronger varieties of the H.P.s. From two to four of the longest and best-ripened shoots of the previous year are carefully bent downwards and secured in a horizontal position by pegs or, what is sometimes more convenient, by tying them to long pieces of strong telegraph wire inserted in the ground. They can either be left their whole length or shortened somewhat to suit the space they are desired to cover. These shoots will flower up their whole length and the plant will throw up strong shoots from the base. In the following spring the shoots that have flowered are cut right away, and the requisite number of young shoots bent down to take their places. By this method we secure a result similar to that aimed at in close pruning, namely, the renewal of the life of the plant by the production of strong shoots from the base and the annual removal of all the old wood.

One matter that has of late years

acquired some importance must be mentioned, and that is the necessity to examine carefully the cuts made in last year's pruning, whether it be left or cut away. If a little hole is found in the stem it shows that the larvæ of a Saw-fly have found a winter home there, and either the shoot should be cut off and burnt or the stem slit down till the grub is found and destroyed. These Saw-flies have recently become a serious nuisance to the Rose-grower both in France and England, and a good deal more information as to their life history is desirable.

The Rose-leaf-curling Saw-fly has, I

NEW OR NOTEWORTHY PLANTS.

PRIMULA WINTERI.

HE is a bold man who proposes a new name for a Primula from the Himalayas, yet this appears to be the commonsense way of dealing with the distinct and beautiful blue Primrose shown at the meeting of the R.H.S. last Tuesday by Messrs. R. Gill & Son, Penryn. It was raised from seeds collected in Kumaon by a Mr. Winter, the plants shown being about 10 months old. They were grown in a cold frame, but Mr. Gill states that equally good plants were produced in the open without any protection.

serrated, mealy and green leaves, many or few sessile or pedicelled flowers, more or less deeply-cut calyx, mealy on the outer or the inner or on both surfaces, and a longer or shorter corolla tube with very variously-formed lobes. . . . Many of the forms are, no doubt, constant and reproduced with much constancy by seed." He also recognised six varieties of *P. petiolaris*, another most variable Primula. One of these varieties, called *pulverulenta*, may be the same as Messrs. Gill's plant; unfortunately, we have already a Chinese Primula named *pulverulenta*, and as typical *P. petiolaris* is not mealy and has elliptical leaves, it simplifies matters to name the Kumaon plant after the man who collected and sent home seeds of it, although botanically it may

FIG. 63.—PRIMULA WINTERI, RECENTLY INTRODUCED FROM THE HIMALAYAS. COLOUR OF FLOWERS PALL PURPLE. (Awarded R.H.S. First-class Certificate on Tuesday last.)

think, two complete life cycles in the year. The eggs laid in the curled leaves in May produce larvæ, which pupate and hatch out Saw-flies in early September, and these lay eggs again in October. As to what happens to them later I have no certain information. I have not at present any evidence that they are the same variety of Saw-fly one finds in the rose-wood, and the books say they are different. The Frenchmen suggest they have an affection for Parsley! *White Rose*,

Primulas are notoriously difficult to classify, and this is particularly the case with the Himalayan species. The wild plants vary so much that it is impossible to say which are species and which varieties; and some of them are probably hybrids. Sir Joseph D. Hooker, in the *Flora of British India*, says of *P. Stuartii*:—"After long study, I am unable to draw any specific characters between the many forms of purple and yellow (rarely white) Primulas included under this. If there are species amongst them, they hybridise so as to defy recognition by description. Each of the following five varieties may have its small and great form with narrower or broader, entire and

be included among the forms of *P. petiolaris*, which is abundant in the temperate Himalayas, where it flowers in autumn and winter.

P. Winteri (see fig. 63) has the habit of the common Primrose, with obovate spatulate leaves 4 inches long, the flat blade 2 inches wide, the base narrowed to a stout petiole, margins irregularly toothed; the whole covered with whitish fine meal, as in *P. denticulata*. Flowers are borne in a crowded umbel on a very short scape, with 20 or more flowers in the umbel. Stout plants produce several umbels, the effect being that of a well-flowered type of the common Primrose; calyx ½ inch long, narrow, urceolate, ribbed,

with teeth-like lobes; corolla tube narrow, 1 inch long, inflated half-way up, limb flat, 1¼ inch across, formed of five broad, roundish lobes, elegantly toothed, and coloured pale purple, with a broad, white ring surrounding the yellow eye; underside mealy. W. W.

NOTICES OF BOOKS.

BRITISH FERNS.*

THE appearance of a new illustrated book on this subject is an indication of a revival of public interest in a branch of horticulture formerly popular, but which has, of late years, been somewhat neglected. The author is well known as a prolific writer on this subject.

The present book may be conveniently divided into three parts, consisting of (1) ten short introductory chapters on life history, selection, culture, &c.; (2) a list, with short descriptions and many illustrations, of the species and varieties; (3) an appendix of 96 nature prints of varieties selected from those printed by the late Col. A. M. Jones, of Clifton, and reproduced on a reduced scale, together with his notes and descriptions.

The opening chapters are almost uniformly excellent. The author writes *con amore* and with a thorough knowledge of his subject. In Chapter I. he pleads for a more discriminating study of varieties, and protests against the wholesale destruction of species by hawkers and other vandals, among whom he includes, not undeservedly we think, the pseudo-scientific collector of herbarium specimens. In the "Life History of Ferns," not the least interesting part is the account of the discovery by the author, and the subsequent working out by Professor Bower and others of the curious phenomenon of apospory. The chapter on selection gives as examples the evolution of three very beautiful new groups of varieties by sowing and selection. Two of these are from the author's own work and, in all, the workers are to be warmly congratulated on the results of their efforts.

The descriptive parts of the volume are of somewhat unequal quality. The descriptions of species are popular rather than scientific, but this is the less to be regretted, since full botanical descriptions may be found in the numerous books on the British Flora. With regard to the varieties, it is clearly impossible, in a book of moderate size, to give complete descriptions, and the section is consequently reduced to little more than a catalogue, although the brief descriptive notes are often illuminating and are assisted, in many instances, by woodcuts and in a few by coloured plates. We cannot think, however, that the best use has been made of the available space, since many obsolete and obscure forms are figured and described with as much detail as is given to the better ones, and some of the latter are omitted altogether. Many of the forms figured are really handsome, especially those of the plumose and crispum (in *Sclopendrium*) sections, and the neater crested ones; but it is not difficult to pick out a score or two which could have been well spared, and room would thus have been found for a greater number of illustrations of the more choice varieties.

The appendix, which occupies more than a third of the volume, is alone worth the price of the book. All the varieties printed, with one or two exceptions, are of the highest excellence as garden objects, and most of them exhibit the characteristics of the varieties in the highest development. The notes by Col. Jones are, if possible, still more valuable than the prints, as the histories are recorded with extreme care, and can be thoroughly trusted. Fern-growers should be grateful to Mr. Drury, and to Col. Jones's representative, for the publication of these prints and notes, which have for so long remained unknown.

* *British Ferns and their Varieties*, by Charles T. Drury, F.L.S., V.M.H., Routledge. Price 7s. 6d.

There are a few discrepancies between the descriptions and nomenclature in the appendix, and those in the body of the work, and in the latter a few printer's or clerical errors which should be corrected in a future edition.

Notwithstanding defects, however, the book is the best yet published on this subject, and it is one which no Fern-lover can afford to neglect. It is handsomely got up and well printed, and forms altogether a most attractive volume. P. W. Stansfield.

SIMPLE LESSONS IN NATURE STUDY.*

THE purpose of this little book is to assist those who are engaged in the teaching of nature study. Any book which achieved this end would be a great boon; for it is certain that natural history is both one of the most interesting and worst-taught of school subjects.

Though these simple lessons have one outstanding merit, namely, that of simplicity, we cannot feel that they are altogether satisfactory. For without being disposed to pedantry, we would urge that accuracy is, above all, essential to the teacher, and yet, on p. 12, he is informed that the coats of seeds are full of tiny holes, through which air and moisture pass. They are not.

The time-honoured partial truth that "in the day time plants give off oxygen; at night time they give off carbonic acid gas—men and animals breathe oxygen always," forms the legend of a confused picture (p. 30) of cows, pigs and Poppies, and on p. 31 is the statement that the portion of the plant which escapes on burning was taken chiefly from the air.

In the section devoted to the "work of leaves," not a single experiment is described or referred to—the scholar is apparently to be told things only. The least the teacher can do is to demonstrate experimentally the work of the leaves to his class; if he cannot for one reason or another do that, he had better leave the subject alone. The latter part of the book is devoted to animals, and, like the former part, is illustrated by numerous figures.

THE LIVERWORTS.†

THOSE who are acquainted with Sir Edward Fry's interest in mosses, and with his contributions to the literature of the subject, will open this dainty little volume, dealing, as it does, with a kindred race of plants, with expectant interest. Nor will they be disappointed with it. The subject is charmingly handled, and the amateur, as well as the professed botanist, will find much of value within its pages. Most people, perhaps, and especially horticulturists, are accustomed to regard liverworts as an intolerable nuisance, if, indeed, they recognise them at all. *Marchantia* and *Lunularia*, two common forms met with in every fernery and the cooler houses, are apt to grow rampantly when they are not wanted, but, after all, they are merely the ruffians of an otherwise delicate and delightful race, and even they will repay nearer study. The liverworts stand at the parting of the ways between the lower and the higher plants, and they show innumerable foreshadowings of those specialisations in vegetative form which have proved so entrancing a subject of study in connection with the vegetative adaptations of the flowering members of the vegetative kingdom. Thus, although in themselves, perhaps, most of the liverworts possess but little horticulture (*sensu stricto*) interest, still to the intelligent lover of plants they hold forth the promise that they will repay closer study.

The book is one we can cordially recommend to all whose keeness in plants travels beyond pure floriculture, and we are convinced that the knowledge now rendered so accessible, and, we would add, presented in such an attractive form, will be gladly acquired by many who have hitherto been debarred from it.

* By John O'Neill, (Hackie & Sons) Es.

† *The Liverworts, British and Foreign*, by the Rt. Hon. Sir Edward Fry, G.C.B., with the assistance of Agnes Fry, (London: Witherby & Co.) 1911. Price 1s. 6d.

FLORISTS' FLOWERS.

THE DAHLIA.

TUBERS which were stored in the autumn have doubtless been examined several times and the decaying portions removed. The best method is to cut such parts clean away and give the cut surface a dusting with powdered lime. If cuttings are not required, the tubers should be allowed to remain in their winter quarters until March, but if it is purposed to increase the stock by means of cuttings the roots should be started as soon as possible in a warm greenhouse. They can either be planted out in a bed of soil and cocoa fibre on a greenhouse stage, or be put into boxes or pots filled with similar materials. At first very little water should be afforded, but when growth commences, which will be indicated by the buds beginning to swell, moisture may be given freely. The first growths are usually rather thick and are difficult to root; it is the custom of the best propagators to discard such growths. They may be cut off about an inch above the crown of the root, when, in a few days, fresh, young, wiry growths will spring from the base of the part of the shoot left. These secondary shoots make excellent cuttings and root readily in sandy loam, provided a bottom heat of about 65° to 75° is afforded. The cuttings require to be shaded and watered carefully to prevent damping.

POT ROOTS.

Pot roots, that is roots which were grown all last season in small pots instead of being planted out in the usual way, should shortly be started in a temperature similar to that indicated above. The great advantage of growing Dahlias from pot roots is that stronger plants are obtained by planting-out time, and they bloom earlier. The small roots should be potted up singly into 60-pots, and after the plants are 6 to 9 inches tall they should be shifted into larger pots. This may be done twice before June with great advantage if early flowers are required. When the time for planting-out arrives it is possible to have fine, bushy plants nearly 18 inches tall. During the month of May they must be grown for the most part in an almost cool greenhouse or frame, every precaution being taken at night-time, if in frames, to cover the glass as a protection from frost. At no time should young Dahlias be cramped for space, for they grow undesirably tall, unless plenty of room is allowed them. D. A.

AMERICAN NOTES.

AMPELOPSIS VEITCHII.

YOUR leader in the issue for December 10 last was very interesting to me, as it carried me back to my halcyon days when, as a young man, I thought myself (from the tuition I had received at Longleat) equal to any gardening occasion. It appeals to me particularly, in that I claim to have been the first to introduce and offer for sale this charming climbing plant in the United States. I heard of *Ampelopsis Veitchii* when it was exhibited at the first Paris International Exhibition by the Messrs. Veitch, where it attracted much attention. It was exhibited growing on a slab of bark, and was beautiful and perfect in appearance.

The plant was, as you say, sent out by James Veitch & Sons in the fall of 1868 and spring of 1869. I procured plants of it, and, giving generous treatment and growing them on quickly, I soon had a good stock from cuttings. In October and November, 1869, I advertised it for sale in the *Gardeners' Monthly*, then published at Philadelphia. This periodical was edited by Thomas Meehan, a graduate of Kew, and a man possessed of unusual knowledge of trees, shrubs, and plants, as well as of all matters relating to gardening, and whose memory I very

much reverse. As the result of my advertising I sold two plants, but I was not discouraged, being sure it would be wanted in large quantities later on, and the results have borne out my anticipations. Its popularity here is increasing from year to year, and from my selling two plants in the fall of 1869, 2,500 plants of it are now required annually for our present needs. *Ampelopsis Veitchii* is a unique, wonderful climber, adapting itself to all circumstances, and, as you say, "growing an outline of its own, and filling it in perfectly later on." All things considered, I think it is the most serviceable climbing plant in existence; when planted in the right place it takes care of itself.

When first introduced I used it quite freely in hanging baskets, vases, &c., with good effect, as it made a first-rate drooping plant. This variety has been extensively planted in and around Boston, where it has been dubbed the "Boston" Ivy. It is also called the Japanese Ivy, and is perhaps best known as *Ampelopsis Veitchii*, the name by which it will be known the longest. I do not care if the systematist calls it *Ampelopsis tricuspidata*, or *Cissus*, *Vitis*, *Quinaria*, *Parthenocissus tricuspidata*, or *Psedera*. Gardeners will have none of these names. They will continue to call it *Ampelopsis Veitchii* as long as grass grows and waters run.
John Charlton & Sons, Rochester, N.Y.

NOTES FROM SCOTLAND.

FINANCES OF EDINBURGH PUBLIC BOWLING GREENS.

An interesting point arose at a recent meeting of the Town Council of Edinburgh in consequence of a remark by one of the members that the policy of the council was that recreations should be free, at all events beyond the point necessary for regulating play. This was made with reference to a proposal to amend the charges for golf on the Braids golf courses. At the end of the discussion on this matter, Treasurer Leishman elicited the fact that in 1909 the income from all the public bowling greens was £2946 and the expenditure £2338, in 1910 the income was £895 and the expenditure £1,021. It also transpired that the expenditure did not include the erection of bowling houses.

THE STAFF OF EDINBURGH CORPORATION PARKS.

The number of employees in the Edinburgh Public Parks last year was 51 more than were employed in 1894. This fact gives some idea of the increase in the work of the City gardener, Mr. J. W. McHattie, but it hardly conveys a sufficient impression of the vast improvements showing in the Edinburgh parks, gardens, and playgrounds.

PRIZES FOR GARDENS AND WINDOW BOXES.

The Countess of Selkirk, while resident on her late husband's estate of St. Mary's Isle, Kirkcubright, instituted a cottage garden competition, which has had a great influence upon the appearance of the cottage gardens in the neighbourhood. On the death of the Earl of Selkirk the estates passed to another branch of the family, and the Countess removed to Bahnae, in the same neighbourhood, where she continues the annual prizes which served such a good purpose previously. We understand that the Countess of Selkirk now contemplates offering prizes for window boxes in the neighbouring town of Kirkcubright.

DOUBLE SWEET PEAS.

A RATHER prolonged correspondence on the subject of double Sweet Peas has appeared in the columns of *The Scotsman*. Some of the writers appear to know but little regarding the appearance of double Sweet Peas

in Scotland, although not a few interested in the flower are aware that Mr. William Angus, now of Penicuik, exhibited a bunch of double Sweet Peas at an autumn show of the Royal Caledonian Horticultural Society several years ago, and received an award. It is evident, however, that double sports are appearing more frequently than before, and Messrs. Dobbie & Co. have a double Spencer Pea which gives a very large proportion of flowers possessing double standards.

EDINBURGH SPRING SHOW.

THIS show has presented of late years some signs of increased interest, although the attendance is still far from satisfactory, and the Royal Caledonian Horticultural Society always sustains a considerable loss on the exhibition. Thus the receipts at the show last year and the cash for tickets sold in shops amounted only to £159 2s. 6d., while the show expenses amounted to £185 8s. 4d., and the prize money to £201 18s. 3d., a total of £387 6s. 7d., an apparent loss of upwards of £200. There are a few items under different heads which would reduce this deficiency, but, on the other hand, a proportion of the other expenses, properly attributable to this spring show, would increase the debit balance. The spring show is, however, so much an integral part of the society's work that it could not well be dispensed with. Interest in the show to be held on April 5 and 6 next will be increased by the prize called "The Sander Cup," value 25 guineas, presented by Messrs. Sander & Sons, St. Albans, for the Orchid group class, the cup to become the property of the competitor who wins it thrice. A cash prize of £3 3s. goes with the cup. S.

MARKET GARDENING.

CUCUMBERS.

THOSE who cultivate Cucumbers for market usually grow the plants on ridges or mounds of soil placed on borders on either side of a central pathway, in low, span-roofed houses, running north and south, and varying in length from 100 to 200 feet, and in width from 12 to 15 feet. Some growers sow seeds in November to raise an early batch of plants that will furnish fruits fit for marketing about the third week in February, when Cucumbers realise good prices. Other growers sow the seed a month or six weeks later to raise plants that will produce good saleable Cucumbers by the middle or end of March. The cost of production is much lower by this latter method, and the crop usually pays quite as well, the weather conditions being more favourable to the building up of strong, free-fruited plants. The November sowing has an advantage in furnishing a longer supply.

The seeds should be sown singly, in the centres of 3-inch pots, filled with a compost consisting of equal parts short stable manure and good loamy soil that has been passed through a 3-inch mesh sieve. The seeds should be placed with their points downwards, and pressed firmly into the soil to a depth of about 1½ inch. Care should be taken to protect the seeds from the attacks of mice by covering the pots with panes of glass or paper until the seedlings appear. The young plants should be shifted into 6-inch pots before they become root-bound, and the soil at the roots should be quite moist before giving them this shift. Place a few potsherds in the bottom of each pot for drainage, covering them with a little half-rotted manure or moss. Use the same kind of compost as recommended above, making this firm in potting. Place a small stick to each plant for support. From the time the seeds are sown until the plants have finished bearing, a night temperature of from 65° to 70° should be maintained, with an increase of 5° to 10° higher

in the daytime: during bright sunshine the temperature may be allowed to reach 95° or 100°, provided there is plenty of moisture in the atmosphere.

The houses should be cleansed thoroughly, washing the woodwork and glass with soft soap and water, and coating the brickwork with hot liquid lime before the borders are prepared. It may be necessary to employ some ground insecticide, such as "Clubicide," to kill worms and other insect pests; but this must be done at least one month before the Cucumbers are planted.

Place freshly-cut turves, grass side downwards, to a width of about 2 feet, keeping the turves nearly close up to the flow pipe on each side of the pathway, the entire length of the borders. This done, coat the turves well over with freshly-slacked lime, to destroy any vermin present. Next place a layer of short stable manure, free from worms, to the thickness of about 2 inches. Upon this foundation, form hillocks, or mounds, at intervals of 2 feet, using the same kind of compost as before, but in a rougher state. About one peckful of the compost will be sufficient for each plant, making the soil firm about the ball of earth and roots in planting. When the roots have pushed through the soil, add fresh compost, placing some of the finer particles around the stems of the plants to encourage the development of roots. Continue to add fresh compost as the roots protrude through the mounds, until the intervening spaces are nearly filled. The houses should be warmed a day or two before the plants are brought in for planting. The holes for the reception of the plants should also be opened in advance of planting, in order to raise the temperature of the compost.

Turves used as recommended above will not only prevent the soil from becoming waterlogged, but will also afford additional stimulating food to the plants when the roots have reached them, at a time when they need additional food to enable them to develop their fruits. Some growers of Cucumbers are unable to obtain turves readily for the purpose indicated; but the results obtained thereby amply repay for their extra cost. By planting on hillocks as advised, the compost is exposed all round to the warmth of the hot-water pipes, thereby promoting and hastening root-growth, and the consequent early furnishing of the trellises with fruit-bearing shoots. Moreover, there is no soil between the plants to become sour before the roots reach it, as is the case where the plants are set out on continuous ridges. H. H. Ward.

SEED POTATOS.

THERE is a good demand for "seed" Potatoes. The variety *May Queen* is selling at £5 10s. per ton, and this probably represents the highest price for any variety. This district is well supplied with Scotch grown tubers for seed purposes; they are sent by water transit, either to Sutton Bridge, Lincolnshire, or Wisbech, Cambridgeshire. In our case we are placing the sets in trays before planting.

BLACK CURRANTS.

OUR oldest bushes, which are nine years old, are being pruned severely. We find that hard pruning results in a development of strong wood, and also assists in the destruction of big-bud. For this trouble hand-picking and burning of the infested buds is practised. If the spring frosts were not so destructive to the flowers, Black Currants would furnish a very remunerative crop.

LIME SPRAYING.

WE have been busy finishing the work of lime spraying, and as birds were very destructive to the buds of Gooseberries these bushes were sprayed twice.

STRAWBERRIES.

SEVERAL acres in this district have been planted with Strawberries recently. The older beds have been cultivated first with the *Planet Jnr.* Scuffler and then with the double-breasted plough. Between the scuffling and

ploughing, a rotary machine has been worked along the rows for sowing manure. Asparagus is largely grown in this district on the flat, and the ground is being treated in a similar fashion to the Strawberry beds.

NARCISSUS VICTORIA.

This fine Trumpet Daffodil is of great promise as a variety for market purposes. A leading salesman in the Midlands has recently stated that, in his opinion, the variety will be in great demand for forcing. Blooms have sold for as much as 4s. 6d. per dozen. It is of the Magni coronata section, and it has a large, bold, erect flower, with broad creamy-white perianth and rich golden trumpet. The variety Cardiff is also in great demand for market purposes, the blooms being especially fine. *Stephen Castle, Walpole St. Andrews.*

NURSERY NOTES.

DELGANY NURSERIES, CO. WICKLOW.

ANYONE in the neighbourhood of Dublin, and who has an hour or two to spare, could not spend it better than by paying a visit to the picturesque nurseries of Messrs. Pennick & Co., Delgany. The nearest station is Greystones, a charming little watering-place about five miles south of Bray. It is a pleasant walk from the station to the nursery, either along the main road or across the golf links, the visitor finding a gentle rise all the way until he reaches an elevation of 500 feet on entering the nursery. Thence a magnificent view of the Irish Sea is obtained, and owing to the altitude it almost looks as if one could drop a stone into the ocean. The nurseries face due east, but are also well exposed to the northwards and southwards. The gales from these quarters are sometimes severe and search out the tender plants. At the back of the nursery, and apparently towering above it, is the Sugar Loaf Mountain on the one side, the small Sugar Loaf near the centre, and at the other side the Downs Mountain. Set in such surroundings Messrs. Pennick's nursery grounds, over 100 acres in extent, may be regarded as having been placed in a most ideal spot.

There is practically no glass in the nursery beyond a few small frames and a greenhouse used for the raising of seedlings. Everything is grown as hardy as possible. Being partly situated on the hillside and partly in the valley there is naturally a great range of variation in the soil. On the upper portions a deep rich and rather reddish loam prevails, gradually passing downwards into a more friable material, until peat or almost bog-land is obtained in the hollows. Messrs. Pennick & Co.—whose leading spirit is Mr. Ireton P. Jones—have taken full advantage of these variations of soils and altitudes, and have their wonderfully varied collection of trees and shrubs, herbaceous plants, fruit trees, and Roses disposed to the best advantage.

Notwithstanding the exposure to the keen winds, I was astonished to see so many plants flourishing here that would not well withstand the winter out of doors in the neighbourhood of London. For instance, one of the first things to catch the eye as the visitor walks along the drive is a clump of *Cordyline australis* about 20 feet high, with fine heads of sword-shaped leaves borne on the ends of branching stems. This particular specimen has borne as many as 23 huge clusters of blossoms at one time, and suggests Italy rather than Ireland. A tree of Winter's Bark (*Drimys Winteri*) about 30 feet high forces itself upon the view by its crimson stems and *Rhododendron*-like leaves. It forms an ornamental and picturesque tree when allowed plenty of space, and Messrs. Pennick have a good stock of sturdy young plants. The New Zealand Laburnum, *Edwardsia* or *Sophora grandiflora*, flourishes as well here as I have seen it in Guernsey and Jersey, and there ought to be fine

specimens in various parts of Ireland. One of the Delgany trees is not far short of 30 feet high. The South American Firebush (*Embothrium coccineum*) also does well, but even at Delgany it requires to be sheltered from the north-easterly blasts. In April and May, when almost every young shoot is laden with clusters of fiery-red flowers, there is no more vivid feature in the landscape. Another fine tree not often seen in gardens is *Olea lucida*, an Olive with rich, glossy *Camellia*-like leaves. It makes a splendid compact bush or small tree, the one at Messrs. Pennick's being about 10 feet high, and almost as much through. It is in an exposed situation, and should prove to be hardy in many parts of the United Kingdom. *Myrtus Luma* (or *Eugenia apiculata* as it is sometimes called), a fine Chilean Myrtle, grows remarkably well, and makes fine bushes 6 feet to 8 feet high. During the summer and early autumn months it is covered with masses of large, pure white flowers, which are rendered more conspicuous by the shining, deep green surface of the broadly ovate, apiculate leaves, each about an inch in length. One particularly fine specimen, perhaps the very finest in the kingdom, stands about 30 feet high, and is remarkably impressive when its beautiful cinnam-

Amongst the many kinds of Oaks grown was one (*Quercus glabra* or *latifolia*), which attracted attention. It is an evergreen species, and has broadly lance-shaped leaves about 6 inches in length, perfectly smooth and shining, resembling more a Laurel or a *Rhododendron* than an Oak. As an ornamental plant for the lawn or shrubbery it should prove very effective. It would be impossible in a brief notice to detail all the good things to be seen in the way of rare and beautiful trees and shrubs at Delgany.

Conifers are to be found in abundance, and some fine specimens of *Ataucaria imbricata* about 40 feet high will convey an idea as to the length of time the nursery has been established. As a matter of fact, I believe "Pennicks" dates from the year 1820, when the original proprietor spared no pains to bring together one of the finest collections of plants in the kingdom. His views and his enthusiasm are well maintained at the present day.

Apart from fine specimens of *Wellingtonias* or *Sequoias*, Corsican Pines (*Pinus Laricio*), Stone Pines (*P. Pinea*), of which there is one over 50 feet high, there are thousands of young Larches, Firs, Pines, Spruces, *Cupressus*, *Abies*, Cedars, Yews, &c., all in the best of health.

FIG. 64.—REMOVING A LARGE BEECH TREE AT WARREN HOUSE, MINLEY.

mon-brown bark is seen gleaming in the sunshine. It should be cultivated in all the most favoured parts of the kingdom.

The Snowdrop Tree (*Halesia tetraptera*) is rarely seen in such fine condition as it is at Delgany Nurseries. Here there is a noble specimen about 25 feet high, and in May, when bearing its drooping clusters of pure-white Snowdrop-like blossoms, it is a sight not to be forgotten by the lover of beautiful-flowering trees.

There are several species of *Pittosporum* that may be grown in the open air under climatic conditions like those at Delgany. *P. Mayi* is undoubtedly the best of all as a fine, compact-growing bush or small tree, often 10 feet to 15 feet high, its undulating leathery leaves of a peculiar olive-green always being conspicuous, even at a distance. Other kinds worth mention are *P. engenioides*, of which there is a rarer variegated form, *P. nigrescens*, *P. Colensoi*, *P. Buchananiai*, *P. Tobira* (also with a variegated form), and *P. undulatum*. The Tassel Bush (*Garrya elliptica*) is now a pretty well-known shrub that does well even in the neighbourhood of London. Its relative *Garrya macrophylla*, however, is not yet so well known as it deserves to be. It has large, leathery, oblong-ovate leaves that are distinctly ornamental.

Roses deserve special mention. Messrs. Pennick have devoted several acres to the best varieties. The mountain air and the sea breezes evidently agree with them.

The same may be said of the fruit trees. Here again several acres are devoted to the culture and propagation of the choicer varieties. II.

TRANSPLANTING A LARGE BEECH.

THE illustration in fig. 64 shows a large Beech tree in Mr. Profit's grounds at Warren House, Minley, Hampshire, after its preparation for transplanting a distance of 35 yards. The tree was about 80 years of age, and measured 4 feet 6 inches through the centre of the butt at the ground level. The ball of earth measured 20 feet by 20 feet and was about 6 feet deep, and it is estimated that the tree and soil weighed 120 tons. The ground was excavated for the whole distance of the 35 yards, and the undertaking found plenty of employment for the staff at Warren House from December until the beginning of February, about 1,500 yards of soil being disturbed and afterwards replaced. There is every reason to believe that the removal of the tree has been attended with success.

The Week's Work.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, K. L., Tynninghame, East Lothian.

GALTONIA CANDICANS.—A portion of the stock of corms of *Galtonia candicans* should be inserted at once, the others being planted a few weeks later to provide a succession. The corms are very liable to disease, and it is a difficult matter to retain healthy plants, even by raising seedlings annually. It is a suitable time to sow the seeds; they should be placed rather thinly in rows, and the seedlings allowed to remain undisturbed until they have reached the flowering stage, which is usually when they are three years old.

GLADIOLI.—*Gladiolus Childsii* and the varieties known as *Groff's* Seedlings may be planted at any convenient time from this date; in this case also, a portion of the stock may be reserved for planting later. Both these *Gladioli* are very decorative subjects, and are suitable for planting in mixed borders, where they give the best effect when arranged in masses, placing the corms a few inches apart. Some of the corms of *G. Breuchleyensis* may also be planted now, and I am inserting some of the new hybrids of *G. primulinus* at this date. In northern and cold districts it is advisable to start such varieties as *G. gandavensis*, *G. Lemoinei*, and *G. Nauceianus*, including the blue varieties, under glass. The corms should be arranged almost touching each other on the surface of a 2-inch layer of a light compost in cutting boxes. Stand them in a cool pit or late propagating house. Very little water will be needed till the roots appear, and when the shoots are a few inches high, the plants may be transferred to their permanent quarters, the ground having been previously well prepared. The small corms which are found clustering around the bases of the old ones may be planted in boxes and grown on in a mild heat. If these are dibbled into a border about May or June, and allowed to grow undisturbed for two years, they will furnish a supply of strong flowering plants.

PERMANENT EDGINGS.—*Hypericum calycinum* used as a border plant requires trimming annually. If the shoots have been injured by frost, they should be cut to within a few inches of the ground, otherwise all that is needed is to trim the plants to the desired height and width. Edgings formed of *Cerastium tomentosum* sometimes need renewing, and this may be done now. Small portions of the plants, either with or without roots, should be dibbled into the soil about 2 inches or 3 inches apart, or this *Cerastium* may be planted in the same manner as is practised with *Box*, by simply laying the plants in rows. Plants that need trimming should be cut with a pair of shears, severing the shoots close to the ground. Remove any weeds that are present, and then spread some light soil over the crowns. The plants will also need clipping at intervals throughout the summer months. The yellow leaved *Stellaria* should be treated in much the same manner, but not just at present. The ornamental grass, *Poa glomerata variegata* needs to be divided and replanted annually. The old clumps should be broken into small pieces, and these should be planted close together. By this method a more even edging will be obtained than when large pieces are planted at wider intervals.

THE KITCHEN GARDEN.

By JOHN DURN, Kitchen Garden Foreman, Royal Gardens, Windsor.

CUCUMBERS.—If seeds were sown as advised early in January, strong plants should now be ready for planting out. When the house has been cleansed and the walls white-washed with hot lime, a hot-bed should be formed and mounds of light, rich soil placed 4 ft. apart on the bed; then, after a few days, when the temperature of the soil has reached 85°, the plants may be put out and their roots covered lightly with soil. A few holes should then be made in each mound

to allow of the escape of water vapour and gases from the hot-bed and to keep the soil from becoming too hot. The soil for planting may consist of loam and leaf-mould in equal parts. When the plants have made considerable growth, they will need frequent top-dressings and a moderate quantity of horse-droppings may be mixed with the soil used for this purpose. The atmosphere of the house should never be allowed to become dry or stunted growth and deformed fruit will be the result. With lengthening days, the syringe should be used freely, but care should be taken not to fill the house with steam from overheated pipes. Keep the foliage well exposed to the light, and never allow the growth to become crowded. The number of fruits to be left on each plant must be governed by the demand, and not more should be left than are necessary to keep up the supply. A night temperature of 70° will suit the plants well, and by day the temperature will vary with the amount of sunshine, and may be allowed to rise to 90° by sun heat.

PEAS.—A sowing should be made now to afford supplies in the beginning of July. If the ground was trenched and manured early in the winter, the trenches may be dug 6 inches deep, so that the roots may reach the manure while growing freely. The seeds should be covered with 2 inches of soil taken from the trenches, and the remainder may be worked in amongst the plants when they are high enough to require earthing up. Peas treated in this way are not so likely to suffer from the effects of dry weather as they would be if sown in shallow drills and earthed-up in the usual way, which turns off the rain water so necessary in the cultivation of this crop. *Gradus* and *Early Giant* are good varieties for this sowing, and *Telegraph* sown on the same day will provide a good succession. The first sowing will now be well above the ground, and should be protected from rough wind by placing a few *Spruce* branches along the rows as the ordinary *Pea* sticks are being placed in position. *Early Peas* sown in pots for planting on a south border should be thoroughly hardened off before planting out, and they must be given protection from rough winds.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Mid-Bees.

STOVE AQUATICS.—March is a suitable time for the overhauling of aquatic plants in stove-houses. In some gardens the plants are started into growth earlier than March, but the results are not justified by the extra expenditure of fuel. There are various methods of wintering aquatic plants. In some cases I advise a rest by keeping the plants partially dry for some six or eight weeks prior to starting them in growth afresh. But each case must be governed by its particular requirements. At Gunnersbury we have wintered the tubers of *Nymphaeas* in the soil, merely withdrawing the water from the tanks. We have, in other cases, shaken the soil from the roots and stored the plants in silver-sand in a warm house. Our present practice is to keep the plants in the water, which is kept at a reduced temperature, until the present time, when the tubers are examined. *N. stellata* winters safely in water warmed to a temperature of 55° to 60°, but *N. gigantea* needs about 5° more. Both of these species are deciduous, but others, such as *N. pulcherrima* and *N. zanzibarensis rosea*, only partially lose their foliage in winter. These latter do not naturally lose all their roots during the resting period, hence it is safer to preserve some of the roots. In each case the tubers should be carefully removed from the old soil, cleansed, and potted into small pots. Stand them afterwards in a tub of water in a warm house, whilst the *Lily*-house and tank is thoroughly cleansed and put in order. At Gunnersbury the plants are grown in tanks, some of which are covered with a span-roofed frame, whilst others have no protection, but in all cases the water is warmed. Each spring, if possible, the frames are painted, but when other work prevents this, they are thoroughly cleansed, including the cement work. The tanks are left unoccupied for some six weeks, the *Nymphæas* meanwhile growing in the pots indoors. During that period the soil is prepared and everything got in readiness for

planting in April. We do not cover the whole of the bottom of the tank with soil, but enclose a quantity with clean bricks that are placed loosely together. This bed, when completed, is about 2 feet to 2½ feet in diameter, and three bricks placed on the flat in depth. The soil consists of turfy loam, decayed leaves and road grit. After planting, a clean layer of gravel is covered over the soil, and this keeps the tubers firm. A diligent search is made in the old soil for any offsets of last season's formation. Other choice water-plants, such as *Eichornia crassipes* and *Papyrus antiquorum*, need careful treatment. The former may be increased freely by means of offsets, whilst the latter can be propagated from seeds or by division. The *Papyrus* is a very difficult plant to keep alive throughout the winter, when it is used, as we employ it, to furnish tanks in the open during the summer. *Zizania aquatica*, another graceful water plant, may be raised readily from seed sown each season, the plant being an annual.

STANDARD FLOWERING PLANTS.—*Indocr* flowering plants grown as standards have become increasingly popular of late years, and they are found extremely useful for many purposes. Some of the most suitable plants for the purpose are *Heliotropes*, *Salvias*, *Fuchsias*, *Lippia citriodora*, *Cassia corymbosa*, and *Zonal-leaved Pelargoniums*. It requires a season for the plant to form a fairly good head, and even longer in some instances. Such as lose all of their leaves in winter may be pruned into a shapely head, and, if desirable, be shifted into larger pots. I do not advise reducing the ball of soil in the case of *Pelargoniums*, but rather removing as much of the old surface soil as possible, and then affording top-dressings.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

THE SEASON.—In the early spring months there are frequently periods remarkable for cold north-west winds. At such times there is considerable difficulty in maintaining the proper temperatures in the various houses, especially if the structures are lofty or in other respects inferior. Considerable benefit may be derived from the use of tiffany or mats for protecting the roof-glass during cold nights, but this refers more particularly to houses of low dimensions, such as forcing pits.

FIG TREES IN BORDERS.—The earliest trees are now growing freely, and the fruits are swelling. Attend to the tying down of the growths and to the stopping of the shoots at the fourth and fifth leaf. If there is no likelihood of the trees being crowded with shoots, it will be desirable to remove entirely those which appear weakest. The thinning may be extended also to the fruit, if there appears to be an extraordinary crop. Remove the less-promising fruits from portions of the tree where they appear too numerous. Syringe the trees thoroughly in the morning and afternoon with clear water, for if this syringing is neglected the foliage is almost certain to become infested with red spider. Admit air to the house in the morning, when the weather promises to be bright, and the atmospheric temperature has commenced to rise; increasing the amount of air gradually if the weather renders this desirable. Vigorous trees bearing satisfactory crops of fruit require frequent supplies of manure water; the borders should not be allowed to approach dryness. They may be given a mulch of farmyard manure which is well decayed.

EARLY FIG TREES IN POTS.—Continue to afford applications of diluted farmyard manure to plants now swelling their fruits. Maintain an atmospheric temperature at night of about 65°. Attend to the stopping and thinning of the growths, and as the fruits approach ripeness expose them to the light and air. Employ the syringe frequently and maintain a moist atmosphere in the house, remembering that when the earliest fruits commence to ripen it will be necessary to discontinue the use of the syringe to some extent, this being conducive to good quality in the fruit. At that stage an increased amount of air should be admitted to the house, but the temperature should not be allowed to fall to any great extent.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

MILTONIA.—*M. vexillaria* is the most popular species of this genus, owing to the amenability of the plant to cultivation, and to its value for decorative and exhibition purposes. The practice of growing plants in a high temperature has been almost discontinued, most cultivators having learned that the temperature that suits the plants best is one a little higher than that of the cool house. *M. vexillaria* is a restless Orchid, which frequently starts into growth again as soon as the pseudo-bulbs are completed; the roots also are nearly always active. This being the case, it is clear that no long period of rest is needed, although, for obvious reasons, there must be some difference made in the treatment afforded in the various stages of the plant's growth. At the present time the plants are developing their flower-spikes from the partially-developed growths, and they are producing fresh roots freely from the base; therefore, from now onwards till the flowering season is past, a more liberal treatment is required than hitherto. An increase of moisture both at the root and in the atmosphere should be given, and the foliage should be syringed freely with tepid soft water whenever the weather is favourable. In a suitable atmosphere and conditions, the plant can be kept free from insect pests, but every endeavour must be made to prevent thrips, and especially the small yellow thrips, which are very fond of the tender flower-buds. Should the thrips put in an appearance, a mild fumigation with some safe vaporising compound should be employed at intervals until the pest is destroyed. *M. Roezlii* and *M. Bleiana* need similar treatment, except that *M. Roezlii* should be placed in a shaded corner of the warmest house, whilst *M. Bleiana* should be placed in a similar position in an intermediate house.

REPOTTING.—The present is a suitable time to repot any vigorous plants that require more rooting space. The roots should not be disturbed more than necessary, and the developing growths will soon produce numerous roots, which will quickly get a hold of the new compost. *Miltonias* are frequently given too great a depth of rooting material. Pans are better than pots for receptacles, and these should drain two-thirds of their depth with potsherds. A suitable potting mixture is one composed of *Osmunda* fibre two parts, *Poly-podium* fibre one part, and *Sphagnum* moss one part. Press the materials moderately firm, and apply to the surface a thin layer of clean peat *Sphagnum*-moss, which should be clipped neatly. Exhausted specimens may also be given attention at the present time by breaking up and starting them afresh. Plants so treated must not be allowed to bloom next season.

MILTONIA SPECTABILIS.—This species, with its varieties and others of the late-summer and autumn-flowering species and hybrids, require a shady position in a house where an intermediate temperature is maintained during the whole of the year. The plants are now making their growth and require copious supplies of water at the root. This section has creeping rhizomes, and require more surface space than *M. vexillaria*, for instance. If any of the plants are needing more rooting material, it should be afforded just before the growths are about to produce new roots. The potting compost may be similar to that employed for *M. vexillaria*.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

The general grafting of Apples, Pears, and Plums may soon be commenced. Young trees may be purchased at such nominal prices from the nurseries that many gardeners do not find it desirable to raise young stock by grafting, yet it sometimes happens in the garden there are one or more thriving trees that are either worthless varieties or bad bearers. In such cases the trees may very well be headed down and grafted with an approved variety. This method often gives better and quicker results than are obtained by removing the trees and planting young ones. Grafting is the mode of propagating many kinds of fruit trees at this time of the year. They are also propagated by budding in the months of July and August, but this latter method will be ex-

plained in a subsequent calendar. In grafting, it is necessary that a perfect adhesion should take place between the stock and the scion; to secure this end great care must be taken that the barks of both stock and scion are placed in close contact with each other, for success very largely depends upon an accurate adjustment. Where the stock and scion are similar in size the adjustment can scarcely fail to be accurate, even in unskilful hands. Cleft or crown-grafting is the method generally adopted when dealing with established trees that have been headed down for re-grafting. When it is intended to renovate a tree all the branches should be headed and grafted. Two or more grafts may be placed on each branch according to its size, so that the success of one at least may be almost certain. This mode of grafting consists of cutting a triangular notch in the stock, into which a correspondingly prepared scion is fitted. This method is preferable to the older one of splitting the stock and inserting the scion. Rind grafting may also be resorted to where the bark or rind is easily lifted. This method consists of making a vertical slit in the bark, and inserting a thin-cut, properly-prepared scion. Side or whip grafting is the method usually employed when dealing with young stocks, or when it is desirable to furnish a tree with side branches where these are deficient, as is sometimes the case with wall trees. Whatever may be the method of grafting adopted, after the fitting together of scion and stock, they should be firmly secured with raffia or budding cotton, and the whole covered with grating wax or clay. The sole purpose of these coverings is to protect the surfaces of both scion and stock from extreme influences of the atmosphere, so that it matters but little what materials are employed, so long as they will not act injuriously upon the cut surfaces of the bark. A good grating mixture is one composed of two-thirds strong clay and one-third cowdung, with an admixture of finely broken moss or chopped hay and straw. Thoroughly mix these materials together several days before being required for use, adding just sufficient water to make them bind together. Grafting wax may be made by mixing together Burgundy pitch two parts, and spirits of wine (alcohol 95 per cent) one part; dissolve the wax in a saucepan over a slow fire, then gradually add the spirits of wine and boil together for three or four minutes, thoroughly stirring the mixture meanwhile; this may be used quite cold, and is easily applied with a suitable brush. A useful and easily made wax may be made of equal parts of lard, beeswax, and resin, melted and thoroughly mixed together. A composition now extensively used is the *Mastic L'homme-Lefort*; it is cheap, easily applied, and may be used cold; it is generally acknowledged to be a perfectly safe paste to use.

THE FRENCH GARDEN.

By PAUL AGATIAS.

THE HOT-BEDS. The Radishes are ready for pulling, and directly the Lettuces are growing well, they should be removed with delay. Radishes are not considered a very remunerative crop, yet they are always grown as the first crop of the year. The earliest Lettuces should be ready for cutting, and the heads should command good prices, as they will be in the market before the bulk of the crop arrives about the 20th of March. The time for the removal of the Lettuces depends largely on the size of the Carrots growing in the same frames, as the Carrots must not be overshadowed by another crop if profitable results are desired. The hot-beds are now completed for the placing of the cloches. The third batch of *Cos* Lettuces "*Cosy of Paris*" should now be planted, one in each space between the cloches on the north side. By planting the three batches of *Cos* Lettuces at an interval of 8 or 10 days a succession is assured, and it permits of the transfer of the cloches early in May.

FRAMES WITHOUT HOT-BEDS.—The first batch of Cauliflowers is now being planted in these frames. The variety being either "*Diamant*" or "*Leerd*"; of these large-growing sorts, five plants should be allowed per light, but smaller varieties, such as "*Early London*" or "*Salomon*," may be planted six plants to each light. The larger varieties are preferable for market purposes as they compete successfully with

the Dutch Cauliflowers. Some growers plant eight *Cos* Lettuces instead of the Cauliflowers in each light, but this method is not a profitable one. Cauliflowers are also set under each cloche in the outside rows in the cold beds; the middle rows are planted with *Cos* Lettuces. As the growth of the Lettuces progresses, much attention is paid to the covering of the cloches, so as to minimise any danger from a check, owing to changes in the temperature. This detail is often overlooked, probably because the damage caused to the leaves is apparent only in the first days of April.

NURSERY BEDS.—The Melons sown early last month are ready for potting in "60" pots in a compost of equal parts good loamy soil and well-decayed manure that has been silted. The pots are filled with soil to the rims, in order to prevent excess of water reaching the roots, and the soil is not pressed hard. A hot-bed 14 inches in thickness is prepared for the plants. Seeds of Melons are inserted every week in order to have a supply of plants ready for planting at all times. Tomato seeds should now be sown in trays and placed on a mild hot bed close to the glass. To obtain clean and healthy Tomato plants in frames, it is essential that water be afforded only when absolutely necessary. If the soil is in a proper state of moisture before the sowing, or the pricking off is done, the natural dampness of the bed is generally sufficient to meet the demands of the plants, which should be strong, hardy specimens by May 10. A sowing of Cauliflowers should now be made under cloches or in a cold frame. This batch will be planted as an inter-crop amongst Cabbage or *Cos* Lettuces late in April.

THE APIARY.

By CHURTON.

THE "ISLE OF WIGHT" DISEASE AND HOW TO COMBAT IT.—This disease is assuming a very serious aspect, for it has invaded every part of the country. Most beekeepers are aware that nearly all the bees in the Isle of Wight were destroyed by the disease in 1906. I attended a meeting of beekeepers recently, and the matter was discussed in all its bearings. It was decided to institute a campaign against the disease in the locality. Diseased colonies form a centre of contagion, and should be burned, together with all combs and quilts from the same hive. Wash and disinfect the hives, frames, and section or shallow frame racks that have been in contact with the diseased bees. During the spring many colonies will be in want of food, and when the bees find plenty of sealed honey in hives where the bees are dead, they will make the most of their opportunities, carrying home the food and the germs of the disease also. If every beekeeper, who reads these few lines, will set to work in his own district, much may be done to eradicate the disease this year. Some are hoping for legislation in connection with bee diseases, but it will not do to wait until laws are passed, for by then the mischief will have been done.

DYSENTERY. This disease has already made its appearance this year in many parts of the country, and the fact is not surprising when the causes are known; they are: (1) feeding with syrup that was too watery, and consequently could not be sealed before the winter; (2) syrup made of glucose, Beet, or brown sugar, for these increase the amount of excrement and render the bees more liable to the disease; (3) draughty and leaky hives. Dysentery in bees may be detected by the brownish-yellow and evil-smelling excrement voided about the entrances, and in bad cases the combs will be stained with the same. The bees will be seen moving about slowly, and many will be found dead. When bees are in good health they never void the faeces except whilst on the wing, so during wet and stormy weather they are unable to take a much-needed cleaning flight. Good honey and thick syrup made of good cane sugar contain so little waste that bees can bear confinement for a much longer time than when fed on the other foods named.

REMEDY FOR DYSENTERY.—Remove the bees from the infected hives, and, if the combs are filthy, provide clean combs. Contract the brood chamber so as to crowd the bees together, give them some good, warm syrup and a cake of soft candy. Provide warm quilts, making them fit the corners of the hives, and take care that the roof of the hive is watertight.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communication should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. It is noted, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR MARCH.

SATURDAY, MARCH 4—
Soc. Française d'Hort. de Londres meet.
TUESDAY, MARCH 7—Scottish Hort. Assoc. meet.
THURSDAY, MARCH 9—
Soc. Nationale d'Hort. de France (Paris) Exh.
MONDAY, MARCH 13—
United Hort. Benefit and Prov. Soc. Ann. Meet. at R.H.S. Hall, 8 p.m.
TUESDAY, MARCH 14—
Roy. Hort. Soc. Coms. meet and Spring Bulb Show (Sixth Masters' Memorial Lecture at 3 p.m. by Mr. G. F. Scott-Lihot, M.A., on "Origin of Varieties").
WEDNESDAY, MARCH 15—
R.H.S. Bulb Show (second day). Roy. Meteorological Soc. meet.
THURSDAY, MARCH 16—Linnean Soc. meet.
TUESDAY, MARCH 28—
Roy. Hort. Soc. Coms. meet (Lecture at 3 p.m. by Mr. R. C. Reginald Nevill, on "Alpines in Their Native Homes").
WEDNESDAY, MARCH 29—
Irish Gard. Assoc. and Benev. Soc. meet.
THURSDAY, MARCH 30—Torquay Spring Fl. Sh.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—40.9°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, March 1 (6 P.M.): Max. 51°; Min. 38°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, March 2 (10 A.M.): Bar. 30.2; Temp. 54°; Weather—Sunshine.
PROVINCES.—Wednesday, March 1: Max 51° Ireland S.E.; Min. 43° Scarborough.

SALES FOR THE ENSUING WEEK.

MONDAY—
Herbaceous and Border Plants, Hardy Bulbs, &c., at 12; Roses, Fruit Trees, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.
TUESDAY, WEDNESDAY, THURSDAY & FRIDAY—
Final Clearance Sale of Nursery Stock, Utensils in Trade, &c., at St. John's Nurseries, Worcester, re R. Smith & Co., Ltd., in voluntary liquidation, by Protheroe & Morris, at 11.30.
WEDNESDAY—
Hardy Bulbs and Roots, Perennials, &c., at 12; Roses, at 1.30; Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe and Morris.
FRIDAY—
Liliums and other Hardy Bulbs, in variety, Herbaceous Plants, &c., at 12; Roses and Fruit Trees, at 1.30, Imported and Established Orchids, at 12.45; by Protheroe & Morris.

The Destructive Insects and Pests Act.

The report of the Intelligence Division of the Board of Agriculture concerning the proceedings taken during 1909-10 under the above Acts is now published. It contains much interesting information both on the working of the administrative measures which have been framed to cope with certain plant pests and also on the present distribution and possible dangers of these destructive agents.

The bulk of that part of the report which deals with fungous diseases is devoted to American Gooseberry-mildew and the wart disease (black-scab) of Potatoes, the former being the only fungous disease with which it has yet been found possible to deal on administrative lines in this country.

* Copies may be purchased from Wyman & Sons, Ltd., Fetter Lane, E.C. Price 1s. 6d.

According to this official report, American Gooseberry-mildew in 1909-10 spread little beyond the area affected by this disease in the previous year. In all, 3,013 gardens were found to be infected, but of these only 610 showed disease for the first time during the year under review. A considerable number of these cases include allotments in which only a few bushes are grown. The disease is undoubtedly worst in those districts where it was first discovered, but beyond those areas it has not yet become widespread. The districts most badly affected are those where Gooseberry bushes are grown on a commercial scale. Thus parts of Norfolk and the Isle of Ely, Kent, Worcestershire, Huntingdonshire and Cambridgeshire comprise the chief centres of disease, but even in these counties a large number of gardens have not yet become infected.

It is satisfactory to know from the report that in only a small number of cases was the fruit seriously attacked. This is doubtless chiefly due to the effective pruning and tipping of diseased shoots generally practised during the last two winters. It is not surprising that the severest attacks on the fruit occurred in the county where the local authorities did not appoint a properly-qualified inspector to deal with the disease.

In regard to the relative susceptibility of different varieties of bushes, it has been found that Keepsake, Golden Drop, Crown Bob, and Whinham's Industry are the most readily affected. Golden Drop seems to be more liable to attack on the fruit than any other kind. No really immune variety has yet been found, but Whitesmith appears to be only slightly affected.

Little fresh knowledge of the sources of infection has been obtained during the last year. Emphasis is again laid on the possibility of infection by means of returned "empties," and attention is directed to the likelihood of the baskets becoming contaminated even while the "top fruit" is being gathered on account of the fact that the latter is often planted between rows of Gooseberry bushes.

The importance of exercising care in the purchase of new bushes is clearly shown by the proof that the outbreaks of disease in Northumberland and East Suffolk were directly traceable to bushes which had been bought from infected nurseries. Licences are now required to allow of the movement of bushes from infected premises, but in spite of this a few cases are known in which the bushes have not been freed from disease before being planted in a garden hitherto healthy.

Stress is again laid upon the great danger of re-infection arising from the winter spores which drop into the soil from the summer onwards. There is a small amount of evidence to show that these spores may retain their vitality in the soil for more than a year.

Concerning remedial measures, the Board advise the destruction of infected bushes only in exceptional cases, where, for example, a few bushes are found to be diseased, or where the bushes are so badly attacked that it is not possible to prune

away all the infected portions. Spraying in the spring is only advised when it is considered that by this means the fruit will be saved from infection and spraying with liver of sulphur during the summer is left to the option of the grower in most cases. The remedial measure, however, which has undoubtedly proved most effective in fighting this pest is the removal of all diseased wood by pruning and tipping in the early autumn.

The Board have carried out some experiments to test the efficacy of Bordeaux mixture, made up in various ways, as a winter spraying fluid, but no favourable result has come from them. Other experiments have been tried to see if success followed the winter treatment of the soil with Bordeaux, kainit, and lime respectively, but in each case the result was disappointing.

The wart disease or black scab of Potatoes receives considerable attention in the present report. Since the complete life-history of the fungus causing this disease has been followed, the parasitic organism responsible for it has been named as *Synchytrium endobioticum*. Opinion seems to be rapidly gaining ground that this disease has been longer in the country than was formerly thought to be the case. The wart disease is only present to an appreciable extent in certain parts of the country, e.g., Staffordshire, Cheshire, Lancashire, Fife, and even there is chiefly confined to allotments and small gardens.

Experiments have been made to test the effect of treating the "seed" at the time of planting with lime, sulphur, and soot respectively, but none of these substances appears to have any effect in checking the disease. Greater success (see last issue, p. 120) has followed the attempt to discover varieties immune to this pest, and, of the many different kinds tried, the sorts known as Conquest, Langworthy, What's Wanted, and Golden Wonder are almost, if not entirely, immune.

The other scheduled fungous pests mentioned in the report are the Tomato leaf spot (*Septoria lycopersici*) and the Melon and Cucumber canker (*Mycosphaerella citrullina*). The former has not spread beyond the area in which it was first discovered, and is less virulent than before.

The only non-scheduled pest of an allied nature dealt with in the report is that of a bacterium, *Pseudomonas campestris*, which has seriously affected large beds of Horse Radish in Cheshire. According to experiments made at Kew this bacterium is identical with that which causes the black rot of Cabbage.

ROYAL SOCIETY.—Among the 15 names of gentlemen recommended by the Council for election as Fellows of the Royal Society, botany is represented by Dr. LANG, Professor of Cryptogamic Botany in the Victoria University, Manchester. Dr. LANG, who was formerly of Glasgow University, is well known for his researches in the Ferns and Liverworts and for his contributions to the study of "Alternation of Generation" in plants.

JOHN RAY.—Mr J. G. BAKER draws our attention to a misprint in the article on British Botanists printed on p. 115. JOHN RAY was born in 1627, not 1728. He died in 1705.

BRASSO-CATTLEYA SENATEUR DE BAST.—The beautiful hybrid illustrated in fig. 65 is obtained from a cross between *Brasso-Cattleya Digbyano-Mossiae* and *B.C. Mrs. J. Leemann*. The sepals and petals are very broad, and of a pleasing rose-colour. The lip is large, deeply fringed and undulated, the centre being richly coloured with gold, and prettily veined. The

plant was exhibited by Messrs. THEODORE PACWELS & Co., Meirelbeke, near Ghent, at a meeting of the Royal Horticultural Society, on the 14th ult., and it gained the award of a First-class Certificate.

PROTECTION OF BIRDS.—The annual meeting of the Royal Society for the Protection of Birds

will be held at the Westminster Palace Hotel, Westminster, on Tuesday next, March 7. The chair will be taken at 5 p.m. by Her Grace the Duchess of PORTLAND, the President of the Society. The Rev. and Hon. EDWARD LYTTELTON will speak on "Real Friends and Enemies of Birds." The awards in the Public Schools Competition will be presented.

FIG. 65.—BRASSO-CATTLEYA SENATEUR DE BAST: SEPALS AND PETALS ROSE COLOURED, LIP GOLDEN-YELLOW WITH DARK VEINING.

ROYAL WARRANTS TO NURSERY AND SEED FIRMS.—The Royal Warrant of Appointment to the King has been conferred on Messrs. HOBBS, LTD., Dereham; JOHN FORBES, LTD., Hawick; JAMES VEITCH & SONS, LTD., Chelsea; and LAING & MATHER, Kelso.

NATIONAL DAHLIA SOCIETY.—We are asked to announce that a conference on Dahlias will be held at Carr's Restaurant, Strand, on the 17th inst., at 6 p.m. Information respecting the subjects to be discussed will be published later.

THE GARDENS AT THE WHITE CITY.—In preparation for the purposes of the Coronation Exhibition, the gardens at the White City are being remodelled. This year, it is said that there will be a varied display of British plants and blooms. Nearly half-a-million plants have been laid out with a general colour scheme. "Visitors will walk through old-English gardens and will be surrounded by such a varied display of exquisite British flowers as will be a revelation even to the most accomplished gardeners."

THE ST. JOHN'S NURSERY, WORCESTER.—An advertisement in this issue states that Messrs. PROTHEROE & MORRIS will hold the final sale at St. John's Nurseries, Worcester, on March 7 to 10, at 11.30 each day, by order of the Receiver for the debenture holders of R. SMITH & Co., LTD., in voluntary liquidation. This sale will complete a series which has extended over 46 days. The stock of this old-established nursery included many thousands of fruit trees, ornamental trees, specimen conifers and shrubs, herbaceous plants, climbers, and other plants. The area of the nursery was about 250 acres. This last sale will include the remainder of the herbaceous plants, climbers, fruit trees, utensils in trade, and sundries. The freehold of the home nursery, comprising the whole of the glasshouses and large range of pits, has already been disposed of by the firm already mentioned.

WART DISEASE OF POTATOS (see p. 120).—Mr. G. T. MALHOUSE, writing with reference to the *Bulletin* on "Wart Disease," published by the Harper Adams Agricultural College, and reviewed in these columns last week, asks us to state that the word "erroneously" was omitted by an oversight from the last sentence of the *Bulletin*, and that this sentence should read:—"The nodules in the roots of Peas, Beans, Scarlet Runners, and other leguminous plants have also been attributed erroneously to wart disease."

THE RANUNCULUS.—"A bed of choice Ranunculuses presents one of the most attractive objects Nature can exhibit in her gayest mood. There you behold black, purple and violet of every shade mingled with others as white as snow. There you see crimson, red and rose of various tints; orange, yellow and straw of every dye. Many are striped or distinctly as the Carnation; some are red and white, and others scarlet and gold. Numbers are edged like the Protea, having white, buff or yellow grounds, others are shaded, spotted or mottled in endless variety. The sight of such a collection instantly fills the spectator with admiration and delight." These were the enthusiastic words of a great cultivator of Ranunculuses, the Rev. JOSEPH TYSO, of Walsingham, Berks., written in 1834. The methods of culture adopted by the old growers, of whom the Rev. JOSEPH TYSO was a type, are applicable today. The roots should be planted in well-prepared beds in February or early in March. The secret of obtaining success is to keep the plants always supplied with moisture. To help this, a top-dressing of sifted mould and old cow dung spread an inch thick over the beds early in May is desirable. A cloth awning to cover the beds in brilliant sunshine is necessary if the fine,

rich tones of the purple, blue and black shades are to be preserved in perfection. In old days, hundreds of named varieties were grown. Nowadays, though named varieties are obtainable, it is usual to cultivate the fine mixtures that are offered by leading firms under the names of Turban, French and Persian. They are all types of R. asiaticus. The Turban varieties are the hardest, most vigorous and free growing. Their flowers are larger than the others but looser and more open. The French varieties are compact and shapely, whilst the greatest range and brightest colourings are generally found among the so-called Persian varieties.

THE AUSTRALIAN APPLE SEASON, 1911.—The following table, compiled by our special correspondent, is a forecast of the imports of Australian Apples from the present time until the end of July. The average weight of a case of Apples is about 40 lbs.

Dates of Sailing.	Steamships.	Quantities. Cases.	Due in London.
Feb. 15...	Orontes	14,000	April 1
Feb. 17...	Somerset	30,000	April 25
Feb. 18...	Medie	45,000	April 15
Feb. 22...	Macedonia	21,800	April 8
March 1...	Orsova	17,000	April 15
March 7...	Telamon	20,000	April 21
March 8...	India	28,500	April 21
March 14...	Pera	50,000	May 6
March 15...	Otranto	20,000	April 28
March 21...	Afric	45,000	May 13
March 19...	Ascarnus	20,000	April 30
March 21...	Suffolk	30,000	April 30
March 22...	Moldavia	20,100	May 6
March 29...	Otway	20,000	May 13
April 5...	Mongolia	19,900	May 20
April 12...	Orvieto	20,000	May 27
April 15...	Svevic	45,000	June 10
April 18...	Essex	20,000	May 28
April 19...	Hector	20,000	May 30
April 19...	Morea	32,000	June 3
April 22...	Themistocles	32,000	June 11
April 26...	Omrah	20,000	June 10
May 10...	Persic	20,000	July 2
May 16...	Ayrshire	20,000	June 25
May 19...	Orestes	20,000	June 30
June 7...	Runic	20,000	July 30
June 9...	Anchises	20,000	July 17

Total 690,300 cases.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

FOKIENIA HODGINSII (see *Gard. Chron.*, February 6, p. 66)—I have about a dozen small specimens of this new plant raised from seeds sent home by Capt. Hodgins to his sister, who is niece to my employer, Mrs. Wyburn. The seeds were handed to me last April. I do not know of any other case in which seedlings of *Fokienia* have been raised in this country. *F. Hadley Manor Gardens, High Barnet, Herts.*

A NEW WORK ON ENGLISH FORESTRY. I read the review of Mr. Forbes's new work by Dr. Percy Groom in your issue of February 18 with surprise, because it seemed to me misleading to your readers, and unfair to the author. I had read and reviewed the same work in *Country Life* of January 14, to which I will refer any of your readers who may want a good illustration of the different opinions which may be taken by two persons writing from different points of view. Dr. Groom's point of view is, as I understand it, that of a pure physiologist. My own is that of a man who has paid much attention to arboriculture and forestry from a practical point of view; and I imagine that the majority of your readers will also take that view. I thought the book one of the best books I had read on the subject, and said that it should be carefully read by all those who are interested in the subject, as its purchase would be a good investment, and might save a great deal of unprofitable and unsuccessful expenditure on planting, if its conclusions were adopted. Dr. Groom appears to me to have unfairly attacked an author, whose experience in forestry is, perhaps, second to none in Great

Britain, by selecting certain passages for criticism in a manner which misinterprets Mr. Forbes's real views. I feel certain that he could give details of the facts on which he based his statements, and though in some cases these may be opposed to ideas which are founded rather on books than on Nature, yet I believe that Mr. Forbes can defend himself successfully if allowed to do so in your columns or elsewhere. *H. J. Elwes, Coleborne.*

I have taken Mr. Elwes's advice and read his eulogistic review of Mr. Forbes's book. In that review he condemns members of the Land Erosion Commission; in his letter he accuses me of unfairness. I do not know whether or no I ought to be grateful for the distinction; clearly those who differ from Mr. Elwes are to be commiserated. It appears to me that, from the standpoint of public interest, the fairest method of testing the reliability of a book is for the reviewer to consider that portion of the work dealing with the section of the subject on which he is best informed, and that, from the point of view of the author, it is fairest to mention this limitation and to select specific examples, at the same time quoting the author's own words. Such was the method that I adopted. Mr. Elwes, in suggesting that my standpoint is that of a "pure physiologist," might perhaps, in fairness, have mentioned that I have made a practical study of trees and tree-life for many years. But to pass from the unimportant personal aspect of Mr. Elwes's letter, I may be permitted to explain more fully my point of view in regard to Mr. Forbes's book. When forests are already established, and Nature or prolonged experience has taught us the capabilities of a place, work can be continued by practical foresters and the continuance demands no careful analysis of the surroundings or of the demands of the trees, so long as the same forest policy is pursued. But where forests are to be established afresh in this country the matter is very different. In dealing with any proposed site answers must be given to two questions: first, "What are the conditions prevailing as regards soil and climate?" Secondly, "What are the conditions under which the various cold-temperate species of trees can flourish?" Mistakes in answering these questions will end in fundamental errors in answering the third question which is practical. "Are there any kinds of trees that immediately or ultimately can be grown on the proposed site with sufficient profit to the community?" To answer the first two questions, it is by no means sufficient to be merely a practical forester or practical arboriculturist, however able. Answers can be obtained only by the aid of men who have an analytical knowledge of the underlying principles, based upon adequate training in science and forestry. Erroneous conclusions formed in regard to these fundamental problems, if promulgated with authority, are liable to do serious harm to the cause of afforestation in this country. And it was from this fundamental standpoint that I reviewed Mr. Forbes's book. *Percy Groom.*

APPLE GROWING FOR PROFIT.—The articles by *A Southern Grower* are always interesting and of educational value. I was pleased to read his remarks on Cox's Orange Pippin Apple retaining its flavour later than January, whereas the season of this variety is generally held to be November and December. I often wonder that growers, where it succeeds, do not produce a large quantity of this Apple, and store the fruits until late in the new year, instead of relying, for example, on such poor sorts as Bannam's Red Reinette, Sturmer Pippin, and Lord Burghley. *A Southern Grower* has no strong opinion apparently as to the cause of canker, a disease which is responsible for more destruction to Apple trees and greater disappointment to planters than any other pest. Many theories have, from time to time, been advanced as to the cause of canker appearing in Apple trees, but I think we are as far off as ever in our knowledge of the subject and of any cure. My opinion, gained from experience, is that the soil, more than anything else, is to blame. Certain varieties of Apples have not the constitution to withstand the effects of unfavourable rooting medium. As a rule a heavy, cold and naturally retentive ground, with a stronger sub-soil, is a fertile source of canker in trees of many varieties. In such a soil trees often exhibit cankered shoots of the current year. I have always noticed that the trees suffer more

from canker after a wet autumn. There are two points to observe: (1) plant varieties that are known to be immune from canker; (2) in planting, trench the whole of the ground 3 feet deep. Trenching may cost more at the outset, but I am positive it will prove remunerative in the long run, and instead of planting the trees even a few inches deep, plant them on the surface of newly-trenched soil, using just sufficient soil to cover them, always remembering that the trees will settle down later into their proper position. *E. M.*

LATE DESSERT APPLES (see p. 123).—If Mr. Molyneux is correct in saying that there are no English dessert Apples worth eating after Cox's Orange Pippin is finished at Christmas, it is a reproach to the many men who have spent years of their lives in endeavouring to improve the qualities of our Apples. Mr. Molyneux attributes this alleged absence of good late dessert Apples to the shortcomings of the English climate. True, our autumns often leave much to be desired, but a climate which renders possible such a delicious Apple as Cox's Orange Pippin—an Apple admittedly fit to eat at Christmas, and often still later—surely is not to blame for the lack of Apples worth eating later in the winter. For the other late Apples named by Mr. Molyneux are gathered only a little later in the year than Cox's Orange Pippin, and are not exposed to the vicissitudes of climate very much longer than that superb variety. Whilst agreeing with him that many of the so-called dessert Apples in season after Christmas are far from being of first-class quality, yet, in my opinion, there are a few exceptions. Rosemary Russet is a most delicious little Apple, one that, with moderate care, can be had in first-class condition well into March. Its only fault, if it be a fault, is want of size, but for table purposes it will usually be found quite large enough. Like most Russet Apples, it should be stored away from the light and air. In shape it is broadly pyramidal; the skin is yellowish, lightly flushed with red on the sunny side, and covered with light-brown russet. The flesh is tender, but crisp, very juicy, yellowish in colour, and it has a distinctive aromatic flavour. Cornish Gilliflower is another Apple to which I would also give three marks. It is known by name to almost everyone, but comparatively few know it by experience, or this perfectly delicious Apple would be grown in every garden. Although it takes its name from our most western county, yet it is not at all common there; it is much more often grown in fair Devon, where the villagers know and appreciate its good qualities. The fruits are heavy, and, as they are produced on the ends of the branchlets, this variety should only be planted in shelter, or the autumn gales will remove the fruits long before they should be gathered. If the fruits are allowed to hang as long as possible, and are stored properly, they will be well worth eating even in May. In fact, its real flavour does not seem to develop until Christmas is past. *A. C. Bartlett.*

STREET TREES AND GAS EFFECTS.—I read with interest the account on p. 44 of street trees and gas, also the article in the issue for February 12, 1910, p. 101. As one who has had until very recently the control of 12 miles of street trees, I will give some experience of gas affected trees. The trees which were under my care were comprised of Wych Elm, English Elm, Cornish Elm, Sycamore (both green and purple and variegated foliage), Horse Chestnut, Laburnum, London Plane, Canadian Poplar, Lime, Mountain Ash, and Silver Poplar, and numbered almost 3,000 of the finest street trees to be seen in any part of the kingdom. There is no question apart from systematic pruning which should absorb the town gardener's attention so closely as the searching for gas-affected areas and other evils which cause either death or badly-mutilated trees. A fungus attacks the bark of some trees and covers the part affected with little red spots, which if not discovered in time will kill a beautifully-placed branch or the whole tree. If this fungus disease is not understood by those having the care of the trees, it is the easiest thing in the world to come to the conclusion that it is gas which is the cause of the injury or death, because the appearance is much the same. I have made it a personal study to find out the reason of the mischief which affected trees, before

I could report to the engineer in chief that it was gas leakage which was responsible. This has prevented unnecessary complaint to the gas committee of the borough, and I have been able to find a remedy for the fungus disease in a painting over with a mixture of Stockholm tar and flowers of sulphur. If a branch or trunk can be discovered before the fungus attack has got all round it can be saved. Respecting the gas nuisance, I know what it means for a Highways committee responsible for street trees to have to deal with the gas committee which manages the gas mains, also borough engineers who may know their own affairs but who do not understand a town forester's duties and difficulties, nor yet those of a gardener or park superintendent. Officials are often the cause of much unnecessary expenditure through their meddling influence with the expert. All municipal authorities would find it to their advantage to see to it that more confidence is placed in other municipal officials than engineers. I have often thought that a discussion on interference by engineers who are in office where gardeners come under their jurisdiction would create a very profitable source of education to all our craft who are engaged in municipal work, and to others who look forward to such occupation. It is of vital necessity that if a town forester knows his business and he reports certain areas as being affected with gas that his word should be credited, as he is, as your correspondent says, a paid public servant. About three years ago I reported leakages in a certain area, which report was discredited by the gas committee. When I determined to resign my position in consequence, it was decided to open up the gas main for the length of a mile, and it was found that almost every joint in that length was defective. The examination had the double effect of saving the trees and preventing a waste of gas which had puzzled both the gas manager and the gas committee. How did I find out that it must be gas? I had an apprentice with the necessary knowledge of insect and fungous diseases, whom I sent to examine every tree in this particular length of road, with instructions to record in a note-book any diseased or insect-infested branch. This gave the youth valuable work and myself some sure data. Where there was no disease or insect and the tree was sickly-looking, I put men with sharp-pointed steel crowbars to bore into the earth between the line of trees and the gas main, and in every instance where there was leakage it showed by the emission of gas fumes following the pulling out of the bar. This plan of testing for gas I suggest to all who have to do with street trees, and on private avenues which have a gas main running from a town's main; often there are such avenues flanked on each side by banks of shrubs and trees, some of which have died, and a leakage of gas has not been suspected. Where a tree has died from the effects of gas, it is not safe to replant in the same space for a long time; a great deal depends upon the soil, whether it is clay or gravel or sand. These are all matters of much importance for the town forester to study. The question of planting new avenues of street trees is a very complicated one, and no town authority should undertake to embark on any pretentious scheme of planting unless it is guided by a trained horticulturist. Some 10 months ago, I took up my present position as outdoor assistant master and head gardener at the Sheffield Union, and I found a state of things in evidence among the trees on each side of a $\frac{1}{4}$ mile avenue that at once made me report to the guardians that drastic steps would have to be taken to deal with them, and at present I am dealing with them in a drastic fashion. I know of nothing in avenue and street tree culture which is so detrimental to the welfare of the trees as allowing them to become overgrown and full of inside growth which is not wanted. Let there be a good open tree inside, every branch of whatever kind of tree independent of each other, no crossing, with a nice base bearing a shapely pyramid. *V. H. Lucas.*

SEED SELECTION.—The subject of Seed selection, as dealt with by Mr. Scott-Elliott at the Royal Horticultural Hall on the 28th ult., is a matter of the greatest importance to horticulturists. Few persons are more fitted to deal with this subject than are seed-men and seed-growers, for their range of knowledge is wide.

Whilst Mr. Scott-Elliott's remarks were throughout favourable to the selection of the finest seeds, Mr. H. J. Elwes's example of the equally strong growth obtained from small and, indeed, almost starved Acorns, as compared with the growth from quite large, fat Acorns, showed that no rule can be laid down in relation to so uncertain a subject. On the lecturer's hypothesis, the finest seeds from Sweet Peas should come from plants of great height and strength. But far more reliable seeds come from plants 4 feet in height, because whilst the former plants are creating wood or stem, flowers and leaf-production, the latter are centring their efforts on the production of seeds. These sown under most liberal conditions, the following year will excel in strength of growth and of wood production what would come from the very gross-grown plants. In many cases, seeds which are of an even character, though not specially large, give the truest and the desired results. Then in relation to flowering plants, how common it is that specially fine seeds throw somewhat coarse growth and irregular flowers, whereas the smaller seeds, and perhaps rather slower in germinating, give the most perfect flowers and the more satisfactory growth. Seeds, moreover, depend far more on maturation, or perfect ripening, than on size. It is well that the gardener should realise that myriads of plant shrubs and trees raised from immature seeds develop into poor specimens, and, therefore, that he should neglect no effort to secure good seeds. *D.*

SELECT VARIETIES OF PEAS.—I read with interest Mr. Vates's notes on p. 115, and can fully endorse all he says of Chelsea Gem Pea. I have grown it now for the past 11 years in these gardens, and not once has it failed to produce more satisfactory results than any other Pea of this height. Two other varieties I strongly recommend are Criterion and "The Clipper." Criterion is 5 ft. in height, and a prodigious cropper; the Peas are large, and tightly packed in medium-sized pods. I think that this variety is the very best and sweetest flavoured Pea in commerce. "The Clipper" grows 5 ft. in height, is a good doer, and may be recommended as an excellent cropping Pea of very fine quality. Many of the pods are equal in size to the variety Quite Content, and are better filled; we grow three-quarters of "The Clipper" in succession to Criterion, using one quart of seeds to rows 54 yards long. *A. Jeffries, Moor Hall Gardens, Harlow, Essex.*

ROMANCE OF A CLOVER.—A similarly curious history to that of the Grass *Paspalum dilatatum*, in New South Wales, referred to on p. 113 of your last issue, deserves to be recorded of the Strawberry Clover (*Trifolium fragiferum*), a rather rare native of some parts of the British Isles. Some years ago the Hon. Mr. Irving, proprietor of one of the leading Melbourne papers, related to me the story of its introduction into the Colony of Victoria. He had occasion to import a piece of furniture from Ireland, if I remember rightly, and the packing material was thrown out into his farmyard. Soon afterwards a plant of Clover appeared on the spot, which was quite new to the district, and, as it was found to be much more drought-resisting than the ordinary species known to farmers, he perpetuated it, and I believe it is now cultivated extensively throughout Victoria. Perhaps someone on the spot could tell us more about it, as the story, if confirmed, would be exceedingly interesting. *Donald McDonald.*

SKIN POISONING BY IVY.—Two of the young gardeners here were recently engaged in trimming the Ivy which grows on the walls of the mansion, and two days afterwards both complained of skin trouble. In appearance they were suffering from a rash such as would be caused by a bad Nettle sting. One man recovered in a day, or so; the other has been, and is still, covered from head to foot with great sores, and is in a sorry state to look at. His head, arms, and legs are all attacked and he is quite unable to resume work. A doctor who has attended him states that he has been poisoned through cutting the Ivy. Is this of rare occurrence? I have never known such a case before, and should be greatly interested to know if others have any such knowledge. *B. J. Mercer, Winton Place Gardens, Maid tone.*

ROSE RAYON D'OR.—This Rose has been very disappointing as regards propagation. Almost without exception, there has been failure in this country, and I hear the same complaint from Continental friends. It appears to be a very difficult Rose to propagate by grafting. The new class of Roses raised from crosses with *R. Pernettiana* are by no means so certain as others, the wood not lending itself to any excitement from artificial heat. We find the same with the Austrian and Persian Briers, and it was also experienced with *Soleil d'Or* and *Gottfried Keller*; more especially upon plants not grown in pots. There is something peculiarly sensitive about the wood of these Roses, and as many others have been disappointed, it may be some relief to them to hear of its general failure among the leading propagators of the day, who possess every possible convenience. We shall probably be a little more successful with lateral wood from pot plants later on; but at present it appears better to use the wood as buds; even to budding stocks in pots, a method we have found far the best with this section or class of Rose. The flowers and ground plant exhibited at the National Rose Society, and which gained a gold medal last year, were all that could be desired, and I feel we should not condemn the plant too soon. I do not look upon this case as a question of over-propagation alone, because the *Pernettiana* varieties have all been difficult, except as budded plants. Since writing the above, I have heard from the raiser of *Rayon d'Or*, who says he also has had difficulty with this Rose, and attributes it to the soft and unripened wood from last season's dull weather; also the development of "black spot," a complaint to which *Soleil d'Or*—the first of the *Pernettianas*—is very prone. *A. P.*

BROWN OAK.—In the issue of February 4, p. 74, the very interesting question of brown Oak timber is referred to, and I can assure all those who have forestry interests that it is as completely in their hands to grow such wood as it is for a florist to grow a new Rose or Apple. I assisted, in 1858, in grubbing four pollard Oaks that had been bought for fuel, and though three of the trees had pale, shaggy timber of no value, one was of dark, mahogany-coloured wood. Though only a lad I preserved some of the dark wood and have it now. This brown wood was also of a mild, crisp, solid texture, resembling mahogany in colour as well as in working. A thousand times have I wondered if such a specimen existed elsewhere. The circumstance points directly to the existence of a sport, and foresters should graft it upon seedling Oaks by the thousand. It would be well for the Rockingham Forest specimens to be used for this purpose and not to fell them. Some Oak timber is a dark olive green in colour, whilst other trees are notable for their splendid growth. It would pay also to treat these in the same way as breeders of scions for producing timber of high value. *A. Dawson, Teddington.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 23.—An imposing display of flowers was seen at the meeting held on Tuesday last, the Hall being filled with exhibits. The groups were mainly forced shrubs and early-flowering hardy plants, but there were also many showy displays of Carnations, Cyclamens, a few Roses, *Richardia Elliottiana*, and miscellaneous indoor flowering plants. The Floral Committee granted one First-class Certificate and one Award of Merit.

The groups of Orchids were remarkably good and varied, and the Orchid Committee granted one Award of Merit and five Botanical Certificates. The exhibits before the Fruit and Vegetable Committee were not numerous, and this body made no award to a novelty.

At the three o'clock meeting in the lecture-room 101 new Fellows were elected, and Mr. G. P. Scott Elliot delivered the fifth Masters' Memorial Lecture, his subject being "Recent Work in Seed Selection."

Floral Committee

Present: W. Marshall, Esq., and Henry B. May, Esq. (Chairmen); and Messrs. T. W.

Turner, George Paul, C. E. Shea, W. J. James, Jno. Green, G. Reuthe, George Gordon, R. Hooper Pearson, J. F. McLeod, W. Howe, Jas. Douglas, J. W. Barr, A. Kingsmill, E. A. Bowles, W. J. Bean, C. Black, Chas. E. Pearson, E. H. Jenkins, H. J. Jones, Arthur Turner, Chas. Dixon, H. J. Cuthbush, R. W. Wallace, R. C. Reginald Nevill, J. T. Bennett-Poe, Ed. Mawley, W. B. Cranfield, and R. C. Notcutt.

Lady TATE, Park Hill, Streatham (gr. Mr. W. Howe), exhibited a remarkably showy group of forced bulbs, interspersed amongst *Spiraeas*, *Calliopsis purpurea*, *Richardia*, *Rhododendrons* (*Azaleas*), and other forced plants, with numerous Palms and Ferns for relief. The extent of the exhibit showed the great wealth of blooms available for decorative purposes in the gardens at Park Hill at this season. (Silver-gilt Flora Medal.)

Mrs. LESCHELLAS, Highams, Windlesham, Surrey (gr. Mr. Farmer), showed a beautiful batch of *Richardia Elliottiana*, the spathes being extra large and of richest yellow colour. The plants were splendid, vigorous specimens. As a separate exhibit, Mrs. LESCHELLAS showed a group of *Eupatorium bathimum*. (Silver Flora Medal.)

Messrs. R. & G. CUTHBERT, Southgate, again put up a showy group of forced shrubs, of subjects similar to those displayed by them at the last two meetings. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, showed *Rhododendron indicum* (*Azalea indica*) of superb quality, each plant appearing like a posy of flowers. The colour, size, and substance of the blooms were all that could be desired, whilst the varieties represented the choicest in commerce. (Gold Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, filled a large table with greenhouse flowers. In the centre was a batch of fine *Hippeastrums* (*Amaryllis*), in about 30 varieties, the choicer sorts being *Valetta* (crimson), *Hermia* (white and rose), *Orion* (velvety-crimson, with reflexed segments), and *Cygnets* (of a distinct shade, being salmon-rose, with a white edge). *Rhododendrons* (*Azaleas*) were displayed in great numbers, some standards of these being exhibited as a separate group. There were also batches of *Abutilon megapotamicum variegatum*, *Primula kewensis* (a fine strain of this plant), *Boronia megastigma*, *Erlangea tomentosa*, *Kalanchoe Dyeri* (with extra large inflorescences), and *Camellia reticulata*. In another part of the Hall, Messrs. VEITCH showed a large group of forced-flowering shrubs, having a magnificent display of the usual subjects, such as *Rhododendrons* (*Azaleas*), *Laburnums*, *Amelanchier canadensis*, *Lilacs*, and *Deutzias*. Some very small plants of white-flowered *Wistarias* were remarkable for the large number of flowers present, and white-flowered *Lilacs* were equally well-bloomed. (Gold Medal.)

Messrs. W. CUTHBUSH & SON, Highgate, showed an imposing display of spring flowers, forced shrubs, and Carnations, filling two long tables with the various subjects. The flowering shrubs included floriferous *Rhododendrons sinense* (*Azalea mollis*), *Spiraea confusa*, *Magnolia Soulangeana*, *Camellia reticulata*, *Lilacs*, the double white variety *Mme. Lemoine* being remarkably good, and *Viburnum Vossii*. The Alpines were shown in a bank of rockwork, with a row of shrubs at the top, *Ledum compactum*, *Corylopsis panicifolia*, and *Hamaelis Zuccarini* being finely bloomed. The Carnations were, as usual, shown well, the cerise-pink variety *Mrs. Fortescue*, *Lady Coventry*, *Lady Elphinstone* (pink), *Britannia* (scarlet), *White Perfection*, and *My Maryland* (white) being amongst the more attractive flowers. (Silver-gilt Flora Medal.)

Messrs. STUART LOW & CO., Enfield, filled a large table with an assortment of greenhouse flowering plants and Carnations. There were many species of *Acacia*, good *Rhododendrons*, *Grevillea alpina*, *Daphne indica rubra*, the graceful *Eriostemon linearifolium*, *Primula malacoides*, and others. The Carnations represented most of the best kinds in commerce. (Silver Flora Medal.)

Hon. VICARY GIBBS, Aldenham House, Elstree (gr. Mr. Ed. Beckett), filled a large table with Cyclamens. The plants were arranged in batches of different colours, the salmon and white varieties being especially fine. (Silver Banksian Medal.)

ST. GEORGE'S NURSERY CO., Harlington, Middlesex, showed Cyclamens, having the finest plants we have observed so far this season. They were

shown in batches of colours, all the specimen plants being well bloomed. Plants with crested flowers had fringed foliage, some of the leaves being divided at the margins like lace work. (Silver-gilt Flora Medal.)

Mr. SEWARD, The Beeches, Hanwell, exhibited a large collection of Cyclamens, not quite so fine as we have observed from this exhibitor in some previous seasons, but a remarkably fine display nevertheless. (Silver-gilt Banksian Medal.)

Mr. H. BURNETT, Guernsey, again showed Carnations of very fine quality, there being no finer blooms in the exhibition. *Scarlet Glow*, *Mrs. H. Burnett*, *Snow Queen*, *Mrs. Tatton*, and *Aurora* may be mentioned as being especially good. (Silver Flora Medal.)

Mr. A. F. DUTTON, Iver, Buckinghamshire, showed varieties of perpetual-blooming Carnations, including *Britannia*, *Rose-pink Enchantress*, *Rose Dore*, *O. P. Bassett*, *Winsor*, and other well-known varieties. (Silver Banksian Medal.)

Mr. C. ENGELMANN, Saffron Walden, Essex, also showed varieties of perpetual-blooming Carnations, the large crimson *Carola* figuring conspicuously in the group. (Silver Banksian Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, staged a collection of filmy Ferns, having 34 species and varieties. Nothing in the collection approached the beautiful *Todea superba* in its size and general magnificence. The next largest were species of *Trichomanes*, *T. maximum* var. *umbrosum*, *T. radicans* var. *cambricum*, *T. radicans* var. *dissectum*, *T. alabamense*, *T. reniforme* (quite distinct in its leafage), and *T. scandens*. Others of interest were *Hymenophyllum demissum*, *Todea pellucida*, *T. intermedia*, and *T. grandipinnula*. (Silver-gilt Banksian Medal.)

Messrs. J. HILL & SON, Edmonton, filled a large table with Ferns in great variety. There were many specimens with new fronds that were prettily tinted. Amongst these, a plant of *Lomaria attenuata*, about 3 feet tall, had finely-coloured foliage, also the rare *Adiantum Hendersonii*, *A. roseum*, *A. fulvum*, and, in the centre of the group *Polypodium conjugatum*. There were many choice *Gleichenias*, including a good example of *G. flabellata*. *Lomaria aspera*, the Spider Fern, has pendulous growths, and buds at intervals, which give rise to young plants. Along the background were arranged excellent specimens of *Dicksonia squarrosa*, *D. antarctica*, *Nephrolepis elegantissima*, *Platynerium grande*, and *P. Hillii*. (Silver-gilt Banksian Medal.)

Messrs. SUTTON & SONS, Reading, exhibited Tulips in half-circular batches of distinct varieties, bordered with *Adiantum* Ferns. In the centre of the display was a large bay, comprised of a dark-red *Cineraria*, labelled *New Scarlet*, intermingled with the yellow-flowered *Primula kewensis*, a pretty combination of colours. The more noticeable of the Tulips were *Meteor* (rose and yellow), *Apple-blossom*, *Sir Thomas Lipton* (scarlet), *Orange Blossom* (white and yellow), and *Pink Pearl* (blush). (Silver Banksian Medal.)

Messrs. GEO. MOUNT & SONS, LTD., The Nurseries, Canterbury, showed Roses *Richmond* and *Lady Hillingdon*, having the blooms as beautiful as ever. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, again showed varieties of Zonal-leaved *Pelargoniums* and *Cinerarias*, with a few large plants of *Cyclamens*, some of the last-named having crested petals. (Bronze Flora Medal.)

Messrs. R. GILL & SONS, Penryn, Cornwall, showed trusses of *Rhododendrons*. There were also extra large flowers of *Violet Princess* of Wales and the new *Primula Winteri* (see fig. 63), that attracted much attention. (Bronze Flora Medal.)

Messrs. C. BROOKS & SONS, Worthing, Basingstoke, showed flowers of *Primula sinensis*, arranging them in batches of varieties. The finer sorts were *Orange King*, *Delicata* (faint pink with a bold, yellowish rim), *Brooks's White*, *Crimson King*, *Giant Pink* (a very fine variety of this colour), *Queen Mary* (rose with a magenta shade), *Giant Crimson*, *Queen Alexandra* (a large white variety), and *Giant Salmon*.

Messrs. ROBERT SYDENHAM, LTD., Birmingham, staged forced flowers of *Narcissi*, and showed how well bulbous plants and *Lily of the Valley* can be grown in moss fibre, without provision for drainage, having splendid examples grown in this material.

Messrs. BARR & SONS, King Street, Covent Garden, showed an extensive exhibit of early-blooming plants. There were large patches of Crocuses in numerous species and varieties, Cyclamen ibericum, Eranthis cilicica, Snowdrops, Pulmonaria angustifolia rubra, Saxifraga linguata (with large heads of rose-coloured flowers), Lachenalias, Iris stylosa, I. reticulata, and other bulbous species. There were also varieties of Narcissi and a large-flowered strain of Primula obovata named Queen of Roses, the colour of the petals being much deeper than usual. (Silver Banksian Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hampshire, showed choice Alpines in bloom. At one end of the exhibit was a batch of Primula denticulata and its varieties, the plants having splendid inflorescences and sturdy foliage. Other choice plants noticed were Saxifraga burseriana Gloria, Viola gracilis, Bulbocodium vernum, Megasea speciosa rosea, and Anemone blanda var. Ingramii. (Silver Banksian Medal.)

Messrs. BAKERS, LTD., Wolverhampton, staged boxes of Alpine plants in flower, with a showy bank of Rhododendron præcox at the back. Several plants of Daphne Mezereum album were covered with flowers. Amongst the Alpines we noticed good forms of Primula rosea, Anemone ranunculoides, and the double-flowered variety of Adonis amurensis. (Bronze Banksian Medal.)

Messrs. G. & A. CLARK, LTD., Dover, exhibited, amongst other early flowers, some exceptionally fine Primroses in many shades, the purple varieties being especially good. The flowers were very clean, the plants having been afforded the protection of a cold frame. (Bronze Flora Medal.)

Messrs. JOHN PEED & SON, West Norwood, showed a large batch of well-flowered Lachenalias and a few Alpines. (Silver Banksian Medal.)

Messrs. R. WALLACE & CO., Colchester, showed a rock-garden exhibit, varieties of bulbous irises being a feature, especially I. Tauri, I. Danfordia, and I. reticulata. Primula viscosa Mrs. J. H. Wilson was shown well, and other choice plants in bloom were Saxifraga burseriana major, Shortia galicifolia, Tulipa Fosteriana, Fritillaria imperialis chitralensis (with clear, yellow flowers), and Corydalis tuberosa.

Messrs. J. CHERAL & SONS, Lowfield Nurseries, Crawley, staged varieties of Alpines in bloom, with a few dwarf shrubs as a background. Of Erythronium there were E. revolutum, E. Hartwegii, E. grandiflorum, and E. Hendersonii in bloom.

Mr. F. HERBERT CHAPMAN, Guldeford Lodge, Rye, showed bulbous Irises, including many seedlings of I. reticulata and I. Krelagei. The beautiful variety of I. reticulata Aspasia was conspicuous amongst the seedlings. Iris "Melusine" is a pale blue colour. Mr. CHAPMAN also showed a few seedling Narcissi, including Lullaby (poeticus) and Treasure Trove, with a creamy-coloured trumpet, as well as a number of seedling Freesias.

Messrs. T. S. WARE, LTD., Feltham, had fine examples of Pulmonaria rubra, Shortia uniflora, and S. u. grandiflora in a large exhibit of Alpines and bulbous plants. (Silver Banksian Medal.)

Mr. H. C. PULHAM, Elsenham, Essex, also displayed a rock-garden exhibit planted with a variety of subjects.

Mr. JAMES DOUGLAS, Edenside Nursery, Great Bookham, exhibited a remarkably fine specimen of Primula megaseaefolia.

Mr. R. UPTON, Guildford Hardy Plant Nursery, showed hardy plants of early-flowering subjects, including a large number of Saxifragas and Andromeda calyculata in flower.

Mr. GEORGE REUTHE, Keston, Kent, also exhibited hardy plants, including Alpines, and choice flowering shrubs.

Mr. H. HEMSLEY, Crawley, showed a rockery exhibit, well arranged, and planted with suitable subjects.

Messrs. HEATH & SON, Cheltenham, staged a rock-garden exhibit, planted with a variety of subjects in flower, amongst them Pulmonaria azurea (with exquisite blue flowers), and Saxifraga juniperifolia.

The Misses HOPKINS, Shepperton-on-Thames, also showed a rockery, having a very attractive display; coloured Primroses, Hepaticas, Anemone blanda, and Daisies affording bright patches of colours.

Mr. H. WARD, Oak House Nursery, Enfield Road, Southgate, showed Primula malacoides.

Several displays of pictures of floral subjects were staged, including some delightful views in gardens, shown by Miss GUNDRY, Foot's Cray, Kent, for which a Silver-gilt Flora Medal was awarded.

Mr. Wilfred Mark Webb, on behalf of THE SELBORNE SOCIETY, 12, Bloomsbury Square, London, showed an assortment of nesting boxes for wild birds, such as have been used with success in the Brent Valley Bird Sanctuary, where species of birds have been induced to nest that have not previously bred in the district. Some were square, wooden boxes made of plain boards, whilst others were natural logs, mainly of Birch. In some of the latter the tops could be removed, and in others a part in the centre was made to slide out like a drawer for the purpose of cleansing the interiors. These nesting boxes are produced in this country, and have been found as serviceable as those formerly imported from Germany.

AWARDS.

FIRST-CLASS CERTIFICATE.

Primula Winterei.—This is a new Primula from the Himalayas, introduced by Messrs. R. GILL & SONS. The plants, as shown, had something of the habit of the common Primrose, except that the flowers are produced in umbels on short scapes. The flowers were pale purple, and the leaves covered with a whitish meal. The plant is described and illustrated on p. 150. The illustration is of a pin-eyed flower, but other flowers were thrum-eyed, a distinct novelty of great value.

AWARD OF MERIT.

Saxifraga × Burseriata.—This is a pretty and free-flowering hybrid from *S. burseriana* major ♀, and *S. apiculata* ♂. It is remarkable not only for its freedom of flowering and vigorous habit of growth, but also for the evidence it bears of the influence of both parents. For example, in the height of its clustered flower-trusses, the greenish peduncles and calyces, can be seen the unmistakable influence of the pollen parent, *S. apiculata*, whilst the whiteness of the flowers and the crimping of the petals affords evidence of the influence of the seed parent. The spiny and glaucous characters of the leaves again resemble that of the first-named parent, while the size of the rosettes and the decidedly horizontal spread of the leaves of the rosettes favour *S. apiculata*. Apart from its interest from these points of view, the hybrid promises well as a garden plant, and, above all, it is distinct. Exhibited by the raiser, Mr. E. H. JENKINS, Hampton Hill, Middlesex.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair); and Messrs. Gurney Wilson, F. Menteith Ogilvie, A. A. McBean, T. Armstrong, J. E. Shill, J. Charlesworth, J. Cypher, W. H. Hatcher, W. P. Bound, A. Dye, W. H. White, C. H. Curtis, J. Wilson Potter, W. Bolton, John S. Moss, and Walter Cobb.

Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford, Dorking (gr. Mr. White), exhibited a group of interesting plants. The collection embraced well-flowered plants of *Catasetum scurra*, with greenish-veined flowers; *Maxillaria variabilis*; the minutely-flowered *Scaphyglottis Behri*; *Pleurothallis scapha*; and *Masdevallia Chamberlainiana*.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. Day), showed *Odontioda Floryi* (C. Noezliana × *O. Andersonianum*), having a reddish flower that shows the characters of the latter parent.

GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. Davis), exhibited *Odontioda keighleyensis* Fowler's var., which has previously received a First-class Certificate.

H. S. LEON, Esq., Bletchley Park (gr. Mr. Cooper), exhibited a choice selection of *Cypripedium* flowers of varieties raised at Bletchley Park.

Mrs. NORMAN COOKSON, Oakwood, Wylam (gr. Mr. Chapman), displayed a fine variety of *Odontioda Bradshawiae* superba; also *Odontoglossum percutum purpureum*, having a richly-coloured flower, with a white lip; *Dendrobium oakwoodiense*, a hybrid derived from *Dendrobium* "T. B. Haywood"; the broad petals are rosy-purple, and the lip has a dark blotch.

R. G. THWAITES, Esq., Chessington, Christchurch Road, Streatham (gr. Mr. Black), exhibited a small group of choice *Dendrobiums*, including *D. mirandum* (Wiganæ × Thwaitesiae),

D. Austinii, *D. nobile* Thwaites' var., *Odontioda Bradshawiae*, and a good variety of *Sophracattleya warhamiensis*.

EDWARD ROBERTS, Esq., Park Lodge, Eltham (gr. Mr. Carr), obtained a Silver Banksian Medal for a group of *Cypripediums*, which included the beautiful *C. Emile Cappe*, which received a First-class Certificate at Paris; a dark variety of *C. St. Albans*; *C. nitens* Prince Olaf; and *C. beechense* Sander's variety.

Messrs. CHARLESWORTH & Co., Haywards Heath, received a Silver Flora Medal for a large group, consisting mainly of large plants of their well-known hybrids. At the back of the group were many graceful spikes of *Odontoglossums*, and good varieties of *Laelio-Cattleyas*. Other choice subjects were *Zygo-Colax Charlesworth*, *Cologyne sparsa*, *Cypripedium Rossetii*, a splendid form of *Brasso-Cattleya Cliftonii* (*Digbyano-Messie* × *C. Trianae*), *Sophracattleya Marathon*, *Laelio-Cattleya Bella alba*, and a number of *Odontiodas*.

Messrs. SANDER & SONS, St. Albans, obtained a Silver Flora Medal for an interesting group. Amongst the finest plants were *Miltonia* St. Andre (*Roezlii* × *Bleuana*), *Cymbidium Holfordianum*, *C. eburneo-Lowianum*, and *Renanthera lmschootiana*. Several excellent varieties of *Cattleya Trianae*, the curious *Catasetum tridentatum*, and many beautiful and richly-coloured *Odontoglossums* were also noticed in this exhibit.

Messrs. STUART LOW & Co., Bush Hill Park, Enfield, received a Silver Banksian Medal for a good group, in the centre of which were some finely-flowered plants of *Dendrobium Wardianum*, and on either side of these many interesting species, such as *Bulbophyllum cupreum*, *Odontoglossum cordatum* Low's variety, the rare albino form of *O. secptrum*, *Cypripedium Harrisonium* albens, several good varieties of *Lycaste Skinneri*, a large variety of *Cattleya Emd*, and *Cattleya Schroderae* "White Queen," having white sepals and petals, with a distinct flush of colour on the lip.

Messrs. MANSELL & HATCHER, LTD., Rawdon, were awarded a Silver Banksian Medal for a well-staged group of rare and pretty Orchids. The yellow *Phaius flavus*, *Eria lanata*, the new *Odontioda Zephyr* (*O. Noezliana* × *O. Willekeanum*), the rare *Oncidium ampliatum* concolor, a good plant of *Miltonia Bleuana* and a selection of well-flowered *Dendrobiums*, constituted the more important subjects.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, obtained a Silver Flora Medal for a neat group of well-grown plants, including the pretty *Cymbidium Woodhamsianum*, the scarce *Odontoglossum cristatum*, a strong plant of *O. Rollia*, with a spike of more than 50 flowers, *Brasso-Cattleya Helen*, and two distinct varieties of *Odontoglossum Harryano-cusum*.

Messrs. J. CYPHER & SONS, Cheltenham, received a Silver Banksian Medal for a group of excellent *Cypripediums*, some bright-coloured varieties of *Laelio-Cattleya Cappei*, several good spotted *Odontoglossums*, including *O. excellens*, and well-flowered plants of the popular *Lycaste Skinneri*.

Mr. E. V. Low, Vale Bridge, Haywards Heath, showed several distinct forms of *Cattleya Trianae*, the finer being *C. T. The Marquis*, *C. T. Titania*, and *C. T. alba*; also a large form of *Cypripedium Maudie*, and *C. Franconia* (*callo-Rothschildianum* × *callosum* Sanderae), having a large, bold flower that favoured *C. Rothschildianum*.

Messrs. J. & A. A. McBEAN, Cooksbridge, received a Silver Banksian Medal for a group containing several good varieties of *Odontoglossum crispum*, a fine plant of *Cymbidium insigne*, with a grand spike of bloom, several choice *Cypripediums*, and the elegant, red-flowered *Epiphrontis Veitchii*.

Messrs. HASSALL & Co., Southgate, exhibited a pretty variety of *Cattleya Trianae*, with a bluish tinge on the sepals and petals, and a deeper blue on the lip; also *Cypripedium aureum* Hycanum.

Mr. JENSEN, Lindfield, Haywards Heath, exhibited a selection of distinct forms from his well-known type of *Cattleya Schroderae*.

Mr. A. SCHLEIGEL, Lewes, showed *Brasso-Cattleya* Mrs. J. C. Hirst (*B. nodosa* × *C. Trianae*), which has many of the characters of the *Brassavola* parent.

Mr. J. STEVENSON, Alton Manor Gardens, near Derby, sent cut flowers of a seedling *Cypripedium*.

The CURATOR OF THE ROYAL BOTANIC GARDENS, Glasnevin, showed flowers of *Pleurothallis pterygachis*, *P. rhombipetala*, *Ione scariosa*, *Cologyne sulphurea*, *C. Whitmeriana*, and *C. perakensis*, *Eria globifera*, and *Maxillaria Lindenii*.

Messrs. T. ROCHFORD & SONS, Broxbourne, Hertfordshire, exhibited a rich form of *Odontoglossum Thompsonianum*, also a distinct form of *O. lochristiense*, and some good varieties of *Sophranitis grandiflora*.

AWARDS.

AWARD OF MERIT.

Cymbidium Veitchii (*C. Lowianum* × *C. Devonianum*), from Messrs. J. VEITCH & SONS, Chelsea.—An apparently strong-growing plant, with a long spike of 14 flowers; the sepals and petals are a greenish-brown colour, the lip having a large blotch of reddish-brown.

BOTANICAL CERTIFICATES.

Phytolipsis glumacea valida.—A strong-growing variety of *P. glumacea*, with many racemes of yellowish-white blooms.

Dendrobium delicatum (Bailey).—A species having erect spikes of white flowers slightly spotted on the lips.

Maxillaria callichroma.—An elegant species, with yellow sepals and petals, the latter being purplish-brown at the base; the lip has a yellow disc. All three shown by Sir TREVOR LAWRENCE, Bant.

Eria lanata, from Messrs. MANSELL & HATCHER.—A pretty species, with spikes of yellowish-green flowers, with numerous hairs on the outside of the blooms.

Grobha fascifera.—A curious species, shown by Messrs. MANSELL & HATCHER, Rawdon.

Fruit and Vegetable Committee.

Present: C. G. A. Nix, Esq. (in the Chair); also Messrs. O. Thomas, A. Dean, E. Beckett, F. Perkins, G. Woodward, P. C. M. Veitch, W. Poupatt, J. Davis, A. R. Allan, J. Vert, A. W. Metcalfe, G. Wythes, G. Reynolds, and J. Harrison.

The Hon. VICARY GIBBS (gr. Mr. E. Beckett) exhibited large, richly-coloured fruits of Hoary Morning Apple from an orchard tree that was planted 13 years ago.

Messrs. SUTTON & SONS, Reading, had an interesting group of various hardy winter Kales, including, in the centre of the exhibit, some with very ornamental leaves. There were masses of Al Scotch Kale; the dwarf green and purple Arctic Kales, tall stems of Sutton's Hybrid Kale, having smooth leaves and giving a wealth of young sprouts, and Hardy Sprouting having curled leafage. (Silver Banksian Medal.)

A large collection of bottled fruits and vegetables was staged by Mrs. BANKS, Park Street, Grosvenor Square. No one has exhibited better preserved vegetables at the meetings than this exhibitor, who showed Asparagus, Spakale, Peas, Broad and Kidney Beans, Beets, Carrots, Cauliflowers, and Rhubarb. Of fruits there were Apricots, Plums in variety, Loganberries, Gooseberries, and others. (Silver Banksian Medal.)

Sir W. GILBEY, Elsenham Hall, Essex, showed a small collection of preserves and distilled Lavender, and other perfumed waters.

THE MASTERS MEMORIAL LECTURE.

The fifth Masters lecture was given by Mr. G. F. Scott Elliot on Tuesday, February 28, in the hall of the Royal Horticultural Society. There was a good attendance of members, and the chair was taken by Mr. William Bateson, F.R.S. After expressing his views on the subject of the inheritance of acquired characters, the lecturer proceeded to give an account of the results of recent work in seed selection, and emphasised the importance well understood by those who are engaged in the commercial distribution of seeds—of a proper system of seed selection. At the conclusion of the lecture, Mr. Elwes proposed a vote of thanks, and drew attention to the pressing need for the institution of a research station for forestry in this country.

COVENTRY CHRYSANTHEMUM.

FEBRUARY 15.—The annual dinner of the above society was held on this date. The Deputy-Mayor of Coventry, Alderman A. H. Drinkwater, J.P., presided over a numerous company. It was reported that the show held last November had proved a success financially. The schedule had already been drawn up for this year's exhibition, and it was proposed to continue the practice of giving free admission to the whole of the children attending the public elementary schools, besides providing refreshments for those belonging to the charitable institutions in and around Coventry. Alderman Drinkwater was re-elected president; Alderman Batchelor, treasurer; and Mr. G. Griffin, secretary.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 16.—Committee present: Messrs. E. Ashworth, R. Ashworth, Thorp, Ward, Cowan, Keeling, Holmes, Arthur, Crombleholme, Cypher, Sander, and Weathers (hon. sec.).

There was only a moderate display of plants at this meeting, the best group being staged by Messrs. J. CYPHER & SONS, Cheltenham. Particularly noticeable in this display were several fine forms of *Laelia anceps* alba and choice *Cypripediums*. (Silver-gilt Medal.)

J. H. CRAVEN, Esq., Keighley (gr. Mr. Corney), exhibited *Odontoglossum* × *Jasper*, a hybrid between *O. crispum* × *O. amabile*. The Committee desired to see the plant again. *Sophranitis* *Marathon*, from the same collection, received an Award of Merit.

W. R. LEE, Esq., Haywood (gr. Mr. Woodhouse), exhibited *Cypripedium* × *fulshavense* *Plumpton Hall* var., quite distinct in form to the type and much paler in its markings.

S. GRATRIX, Esq., Whalley Range, Manchester (gr. Mr. Brown), was awarded a First-class Certificate for *Cypripedium* × *Duchess of Comaught*, a hybrid between *C.* × *Maudie* × *C. Sanctus*, also an Award of Merit for *C.* × *Prince Albert*.

J. McCARTNEY, Esq., Bolton, exhibited *Lycaste Skinneri* var. *Alice McCartney*, which received an Award of Merit.

Rev. J. CROMBLEHOLME, Clayton le-Moors, exhibited *Cypripedium* × *Youngie*, a cross between *C. bellatulum* and *C. Hookeri*. The plant was given an Award of Merit.

W. THOMPSON, Esq., Stone (gr. Mr. Stevens), exhibited a fine plant of *Cypripedium* × *chryso-toxum*, and he was awarded a Cultural Certificate.

J. J. HOLDEN, Esq., Southport (gr. Mr. Johnson), received Awards of Merit for *Cypripedium* × *Queen of Italy* Holden's var., *Odontoglossum* × *Sambo*, and *O.* × *Purple Monarch*.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Gidden), exhibited *Odontoglossum* × *Ashworthianum*, a hybrid between *O. Uro-Skinneri* × *O. cirrhosum*, a pretty and interesting plant. *O.* × *highfieldense* received a similar award.

Other exhibitors were Messrs. E. V. Low, Haywards Heath; J. ROBSON; A. J. KEELING; and W. SHACKLETON.

LEEDS GARDENERS' FRIENDLY BENEFIT.

FEBRUARY 21.—The 44th annual dinner of the above society was held on this date. Alderman W. Penrose-Green, J.P., presided.

According to the annual report, the society's income for the year amounted to £231 14s. 4d., and the expenditure to £138 4s. 8d., leaving a balance of £93 9s. 8d., which brings the accumulated funds of the society up to £1,765 19s. 11d. The trustees have purchased £200 worth of Leeds Corporation 4 per cent. stock, the total sum invested being £1,700. There was not much sickness experienced during the year, the amount of benefits paid being £52 12s. 1d., and £30 has been paid in sums at death of members, making the total sum paid out of the benefit fund £82 12s. 1d. In addition to this sum, £12 14s. 7d. has been paid in cases of prolonged sickness out of the surplus benefit fund, and grants made to distressed members from the same fund amounted to £1 10s. 7d. Fourteen new members have been admitted, the present number being 161.

Councillor Owen, in proposing the toast of "The Gardeners' Lodge," congratulated the

management upon the extremely low expenditure connected with the management of the society. The balance-sheet, he said, was an excellent one.

The President, Mr. Donoghue, outlined briefly the progress made by the society, stating that over £3,000 had been distributed amongst the members since the society's formation.

Mr. George Carver was accorded a high tribute of praise for his services as secretary. Mr. John Franklin completes, this season, 21 years' service as treasurer.

CROYDON HORTICULTURAL IMPROVEMENT.

FEBRUARY 21.—An illustrated lecture on "Pretty Gardens and Flowers" was delivered to the members of this society on the above date by Mr. M. E. Mills, Coombe House Gardens. Another item of interest at this meeting was a number of photographs in colours taken by Mr. J. Noaks.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending March 1.

The wettest week for over two months.—The past week has been, on the whole, a very warm one, both during the daytime and at night. In fact, there has not been a single cold day and only two cold nights for nearly three weeks. The ground is at the present time 2° warmer at 2 feet deep, and 4° warmer at 1 foot deep, than is seasonable. Rain has fallen on each of the last six days, and to the total depth of an inch—making this the wettest week since the third week in December, or for over two months. The recent dry period may be said to have lasted 42 days, during which only about three-quarters of an inch of rain was deposited; or less than a quarter of the average rainfall for the same 42 days. During the week 4 gallons of rainwater have come through the bare-soil percolation gauge, and 3½ gallons through that on which short grass is growing, which is not far short of the total rainfall for the same six days, showing that notwithstanding the recent long spell of scanty rainfall the soil has remained moderately moist. The average sunshine during the week amounted to 3½ hours a day; or for about three-quarters of an hour a day longer than is usual at the end of February. On two days the sun was shining brightly for nearly eight hours each day; whereas, on two other days, no sunshine at all was recorded. The wind has remained high during the week, and in the windiest hour the mean velocity reached 23 miles—direction W. There was about a seasonable amount of moisture in the air at 3 o'clock in the afternoon. A selected patch of yellow Crocuses in my garden first showed an open flower on February 24. This is one day earlier than the average date for the previous 24 years, and five days earlier than last year.

FEBRUARY.

Warm, dry and windy, with about an average duration of sunshine.—This proved a warm February. The first 10 days and nights were nearly all cold, and the first two nights very cold. On the other hand during the rest of the month the weather continued warm, and for the last 12 days very warm. On the warmest day the temperature in the thermometer screen rose to 55°, which is about the average extreme maximum for the month, and on the coldest night the exposed thermometer registered 22° of frost, which is rather colder than the average extreme minimum for the month. Rain fell on 15 days, and to the total depth of 1½ inch, or half an inch below the February average. Of the total amount two thirds was deposited during the last six days. No snow fell during the month. The sun shone on an average for 23 hours a day, which is slightly above the average duration for February. On 10 days no sunshine at all was recorded. Taking the month as a whole the velocity of the wind was above the average, and the highest mean velocity in any hour amounted to 23 miles—direction W. The average amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by 4 per cent.

THE WINTER.

Remarkably warm, wet, and rather stormy.—Taken as a whole this was a very warm winter, indeed, the warmest with three exceptions during the past 25 years. On the warmest day the temperature in the thermometer screen rose to 55°, and on the coldest night the exposed thermometer showed 22° of frost. The total rainfall amounted to 8½ inches, which is 1½ inch in excess of the average amount for the season. At no time was the ground completely covered with snow. The sun shone on an average for 1½ hour a day, which is slightly above the usual winter duration.

OUR UNDERGROUND WATER SUPPLY.

Since the winter half of the drainage year began in October, the total rainfall has been 14½ inches, or 1½ inch in excess of the average for the same five months in the previous 55 years—equivalent to an excess in rainfall on each acre in this district of 12,300 gallons. At the same time last year there was an excess of 31,445 gallons per acre. E. M., *Berkhamsted*, March 1, 1911.

GARDENING APPOINTMENTS.

Mr. F. WICKENS, for 5 years Gardener to Sir HORACE MARSHALL, The Chimes, Strathallan Common, S.W., as Gardener to Lady BRINCKMAN, Brinstead House, Ryde, Isle of Wight.

Mr. H. HOARE, recently Foreman at Bifrons and Balcombe Place Gardens, as Gardener to F. BARCHARD, Esq., Horsted Place, Uckfield, Sussex.

Mr. A. MADDOCK, for the past 4 years Foreman at Norbury Hall, Ashbourne, and previously Foreman at Hindlip Hall, Worcester, as Gardener to SAMUEL BAWFORD, Esq., Hawthornden Manor, Uttoxeter, Staffordshire.

MARKETS.

COVENT GARDEN, March 1.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing cut flowers and their prices, including Anemone fulgens, Narcissus, Azaleas, Camellias, Carnations, and various other varieties.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing cut foliage and their prices, including Adiantum, Asparagus, Sprengerii, and various ferns.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing plants in pots and their prices, including various ferns, Narcissus, and other potted plants.

Fruit: Average Wholesale Prices (continued).

Table listing various fruits and their prices, including Apples, Grapes, Lemons, Mangoes, Melons, Nectarines, and other produce.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices, including Artichokes, Onions, Parsnips, Peas, Potatoes, and other garden produce.

rooms exceeds the demand; consequently they are cheap. Spring Cabbages are expected to arrive next week. There has been a very large arrival of Cauliflowers from many sources. Brussel Sprouts are finishing. Fair supplies of other vegetables are meeting with a moderate demand. E. H. R., Covent Garden, March 1, 1911.

Potatoes.

Table listing potato varieties and their prices, including Kents, British Queen, Up-to-Date, Bedfords, and others.

REMARKS.—Trade is very little better; prices remain about the same and the stocks in London are still large. Edward J. Newborn, Covent Garden and St. Pancras, March 1, 1911.

Obituary.

COLONEL BEDDOME.—The death of Colonel R. H. Beddome occurred at Sispara, Putney Heath, on the 24th ult. in his 81st year. He joined the Indian Army in 1848, and was appointed Quartermaster and interpreter of the 42nd Infantry Regiment in 1856. In the following year a forestry department was constituted to preserve the forests of Southern India, and Beddome was appointed chief assistant to Doctor Cleghorn, the first conservator. Three years later he became head of the forest department, and he continued to hold this appointment until his retirement in 1882. Colonel Beddome has done good botanical work both in India and since his retirement in England. The best known of his publications is The Ferns of Southern India, containing figures of 661 varieties. This work was published in Madras, 1856 to 1870, and we believe a copy can be seen in the Lindley Library. His other publications include The Flora Sylvatica for Southern India, with plates of 350 trees and Icones Plantarum, containing 300 plates of new and rare plants. The more important of Colonel Beddome's studies, since his retirement in England, are embodied in papers published in the Journal of the Royal Horticultural Society on the Natural Orders Acanthaceae (vol. xxxiv., p. 54), Campanulaceae (vol. xxxii., p. 96), and Gesneraceae (vol. xxxiii., p. 74). Deceased was a frequent visitor at the exhibitions in London, and at Kew Gardens and other places of horticultural interest. He was an occasional contributor to these pages.

ARTHUR RAWLINGS.—The death of Mr. Arthur Rawlings, late of the Dahlia Nurseries, Romford, took place on February 14, at Grand Forks, British Columbia. Mr. Rawlings, who was in his 54th year, was a son of Mr. George Rawlings, of Bethnal Green, a well-known raiser of Dahlias. Mr. Arthur Rawlings, with his brother John, established the firm of Rawling Brothers, Oldchurch, Romford. The brothers were very successful in raising new varieties of Dahlias, and they put into commerce such fine sorts as Frank Rawlings, William Rawlings, J. T. West, Mrs. Glascock, Queen of the Belgians, and T. J. Saltmarsh. The elder brother died in 1890, and after his death the late Mr. Arthur Rawlings appeared to lose interest in the business, especially as the Cactus varieties, for which he cared little, had become the most popular type. In 1900 he decided to relinquish his connection with Dahlias, and proceeded to British Columbia to engage in fruit farming. Unfortunately he settled in a very exposed district, unsuited for fruit growing, and the disappointment he experienced with his new venture helped, it is feared, to hasten his death.

JOHN NEWBOLD COOKE.—The American horticultural papers announce the death of Mr. John Newbold Cooke, of Greenwich, U.S.A. Mr. Cooke was a native of Warwickshire. He emigrated to America 43 years ago to undertake the management of a private estate at Mamaroneck. Later he engaged in business on his own account, and retired in 1906.

SCHEDULES RECEIVED.

Haywards Heath Horticultural Society's summer show to be held on Wednesday, July 26, and Chrysanthemum show to be held on Tuesday, October 31, and Wednesday, November 1. Secretary, Mr. Geo. Prevett, The Rosary, Haywards Heath.

Table listing various apples and their prices, including American, Russets, Ben Davis, Greening, and Baldwin.

* * * The Editors will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for reproduction in this Journal.

BONEMEAL: *A. P., Cambridge.* The quantity of bonemeal to apply to an impoverished soil will vary according to the purpose for which it is supplied, and whether the gardener is using it without dung. If none or but little dung is used, then for fruit borders apply from 6 lbs. to 8 lbs. of bonemeal per square rod. In ordinary garden culture from 4 lbs. to 8 lbs. per square rod may be applied early in spring. If the dung is used the phosphatic manure may be reduced to about half these proportions. As the plants begin to grow, a little active nitrogen in the shape of nitrate of soda may be used at the rate of 4 lbs. per square rod, or a dressing of soot will be useful.

BOOK ON BERMESE ORCHIDS: *General T. The Orchids of Burma,* by Capt. Bartle Grant, Rangoon, printed at the Hanthawaddy Press, 1905. If a cultural work is needed *Orchids*, by James O'Brien [in Present Day Gardening series] price 1s. 6d., with eight coloured plates, would be useful. You can obtain both books through our publishing department.

CALANTHE VEITCHII.—The manner in which you arrive at the conclusion that the *Calanthe Veitchii* spikes, cultivated by Mr. Goodacre in the Moulton Paddocks Gardens, and referred to on p. 50, should be 8 feet long is scarcely to be relied upon. The habit of a *Calanthe* plant, even in respect to the distance which separates the individual bloom upon the flower-spikes, is modified very materially by the cultivation afforded. We have frequently seen instances where the spikes have been long and the flowers few, but, on the contrary, in other cases the spikes do not elongate to so great an extent yet bear a larger number of flowers. As a matter of fact, the spikes of the Moulton Paddocks plants averaged just a little over 6 feet in length. As stated in our note, the number of flowers ranged from 60 to 75.

CROCUSES: *W. H.* It is impossible to form a definite opinion as to the cause of the trouble complained of in your letter, unless specimens of the corns and of the black flies mentioned are sent for examination. We have not any knowledge of failure in Crocuses such as would fit the details in your letter.

DENDROBIUM NOBILE: *J. S.* You ask if growths of *Dendrobium nobile* made during 1910, which have lost their leaves during the resting season at the end of 1910 and early part of 1911, should produce flowers immediately after the resting season is over? The course you mention above is that usually aimed at by growers, though not necessarily for leafless pseudo-bulbs. In the *Gardener's Chronicle*, 1892, there was a discussion about cutting out flowered and flowering pseudo-bulbs of *Dendrobium nobile*, one of the best growers advocating the removal of the entire flowering pseudo-bulbs for decorative purposes, leaving young pseudo-bulbs to supply flowers in the following year. In the *Gardener's Chronicle*, June 4, 1892, p. 725, an illustration of an enormous specimen is given, the plant consisting solely of leafy, flowering growths, which were to be removed, leaving the short, young growths to form a similar plant for the next year. Such plants require a specially moist house. At the same time, *Dendrobium nobile* is obtained from widely separated localities, and there are many distinct varieties in gardens. Differences in cultural methods also give varying results, so that it is by no means uncommon to see the plants flowering from the two-year-old growths or from any pseudo-bulbs which have not flowered previously.

GALL ON OAK: *A. D. W.* The specimen sent is one of the uncommon galls formed by one of the Gall flies (*Cynipidae*). The name of the fly in the asexual stage (as sent) is *Andrius subdoli*. In the sexual stage it is called *A. testaceipes*.

HAILSHAMBERRY: *Rocks.* We believe specimens of this fruit were exhibited by Mr. W. Knight, Hailsham, at the meeting of the Royal Horticultural Society on October 11, 1910.

JASMINUM NUDIFLORUM: *A. P., Cambridge.* As your specimen of *Jasminum nudiflorum* has outgrown the position allotted to it, you may cut it back now with perfect safety in the way you suggest. At the same time, all old, worn-out wood near the base of the plant should be removed. A mulching of leaf-mould may be applied with advantage.

NAMES OF FRUITS: *A. Myhill.* Dredge's Fame.—*F. Carter.* 1, Catshead; 2, Grange's Pearmain.—*J. H. R.* Lodgemore Nonpareil.

NAMES OF PLANTS: *A. G.* 13, *Selaginella stenophylla*; 14, *S. Martensii* variegata; 15, *Phoenix rupicola*; 16, *Asplenium bulbiferum*; 17, *Pteris cretica albo-lineata*; 18, *Begonia albo-maculata*; 19, *Begonia Weltoniensis*; 20, *Begonia echinosepala*; 21, *Cyperus alternifolius* var.; 22, *Eononymus europaeus* variegated variety; 23, *E. japonicus albo-variegatus*; 24, *Asplenium obtusatum*; 25, *Adiantum pedatum*; 26, *A. Pacottii*.—*Perkins, Dorking.* *Dadaloanthus nervosus*, known in gardens as *Eranthemum pulchellum*.—*W. L. S.* 1, *Colletia cruciata*; 2, *Semele androgyna*.—*J. C., Wells.* 1, *Cotoneaster* (the species cannot be determined without leaves); 2, *Juniperus virginiana* var. *Schottii*; 3, *Cryptomeria japonica* var. *elegans*; 4, *Juniperus chinensis* var. *aurea*; 5, send when in leaf, or, preferably, in flower.—*E. T., Hartlepool.* 1, *Hedera Helix roegneriana*; 2, *Pseudotsuga Douglasii*.—*E. T., Hartlepool.* *Cypripedium exul* and *Cattleya Harrisoniana*.—*M. A.* *Dendrobium*. The darkest, rose-purple flower is near to *D. nobile nobiliss*; the one with orange in front of the dark disc of the lip is *D. Cybele* (*nobile* × *Findlayanum*). The others are forms of *D. Ainsworthii*. The *Cypripedium* appears to be a form of *C. Deedmanianum* (*Chamberlainianum* × *Spicerianum*). None is of any exceptional value.—*A. H.* *Dendrobium speciosum*.

PALM UNHEALTHY: *B. S.* A minute parasitic fungus is present. Sponge the plant with a deep rose-red solution of Condy's Fluid.

PELARGONIUMS UNHEALTHY: *A. H. E.* The nature of the injury cannot be determined. It does not appear to be due to fungi or insects, but is probably the result of planting the cuttings too deeply.

PINUS INSIGNIS: *Myrtle.* You may expect the best results from seeds of *Pinus insignis* taken from one and two year old cones, though seeds obtained from older cones will often germinate. The best way to open the cones is to subject them to heat. This may be done by placing them on a shovel and holding them over a clear fire. As soon as they burst remove them from the heat and allow them to cool. The seeds may then be extracted easily. It is also possible to extract the seeds by forcing the scales apart by means of an awl. This can be done by starting at the base of the cone and removing the scales in successive layers. The seeds may either be sown in a bed in a cold frame or in a bed in the open ground. It is a good plan to roll them in red lead to keep vermin away.

PLANTS FOR SUMMER BEDDING: *A. Le Spencer.* You omitted to mention the size of the beds for which the plants are required, and to indicate whether you desire to use annual or perennial plants. A pleasing effect could be obtained by planting your design in the following manner:—(1) a ground work of pink Ivy-leaf *Pelargoniums* with dot plants of *Nicotiana sylvestris*; (10 and 11) groundwork of white Ivy-leaf *Pelargoniums* with dot plants of white flowering *Antirrhinums*; (2, 3, 4, and 5) white Stocks mixed with pink *Antirrhinums*; (6, 7, 8, and 9) mauve-coloured *Viola* with dot plants of double white *Fuchsia*. The combination of *Lobelia cardinalis* with Sweet Alyssum ought to be quite satisfactory. As to whether these combinations of plants and colours are satisfactory or not depends, as a rule, very largely upon individual taste. Variegated Maize, Castor Oil plants, *Solanum pyracanthum*, and *Nicotiana sylvestris* are all suitable subjects for mixing with ordinary bedding plants.

ROSES DISEASED: *J. F. J.* The Rose-rust, *Phragmidium subcorticatum*, is present on the briars. The fungus is perennial in the tissues of the host, and appears from year to year, hence infected plants should be destroyed.

SPOTS ON LEAVES: *F. T.* The spots are punctures caused by insects. No disease is present. Spray the plants with an insecticide.

TOMATO CULTURE FOR MARKET: *A. B.* In an unheated house 20 feet by 8 feet, it will be advisable to set the Tomato plants about 1 foot apart close up to the side walls on either side of the house. That would allow 20 plants on each side. Train these on the single stem system to a trellis fixed at about 1 foot underneath the roof glass. Stop the plants at 3 feet from the groundline after they have shown a few trusses of flowers each. When these have set their fruits and produced a few more trusses of flowers stop the plants again, and so on until the plants have reached the top of the trellis. A few rows of plants may also be grown on the floor space at 2 feet apart, and at 1 foot in the rows on either side the longitudinal centre of the house, stopping the plants after they have shown four or five trusses of flowers. In order to get the trusses set and the fruit well developed and ripened before the plants trained up under the roof glass have made much headway, keep the growths persistently pinched. With generous feeding at the roots and judicious pinching of the lateral growths and leaves, you may secure a crop of 500 lbs. of fruit from your house, provided you have a little artificial heat at command to assist the swelling up and ripening of the fruit in the autumn. A No. 1 Wrought Plain Saddle boiler, capable of heating 150 feet of 4-inch piping, would answer your purpose, and would be available to heat another house or two of the dimensions of your existing one should you decide to make such additions. Of the two kinds of hardy fruit you mention, probably Strawberry plants set at 2 feet apart (say, 10,890 plants) in full bearing, should, if the ground is good and has been liberally dressed with farmyard manure, yield an average crop of $\frac{3}{4}$ lb. ripe fruit per plant, 8,167 lbs. (about 3 tons 12 cwt. of fruit). Thus at 2d. per lb. the crop would amount to £68 1s. 2d. (gross); the cost of gathering the fruit for market would be $\frac{1}{4}$ d. to $\frac{3}{4}$ d. per lb. according to the weight of the crop, £17 at the former price, and £25 10s. at the latter scale. Then if you dispose of your fruit through the medium of a salesman, his commission, together with the expenses of packing and conveyance to the market, should be deducted from the £68 1s. 2d. (gross).

TOMATOS DISEASED: *W. B.* The plants are attacked by the "damping-off" fungus. Water them with nitrate of potash solution, and admit more air and light.

TREE AND BORDER CARNATIONS: *H. H.* The difference between the Tree and Border Carnation is merely in the growth of the plants themselves. The Tree Carnation, like the true border type, throws up a central flowering stem, but it also develops side growths from the main stem, and it continues to do this for several years, forming a tree-like plant. The true Border Carnation does not produce these axillary growths. The Tree Carnation is not adapted for border culture, as the woody stems are killed or badly injured by frosts in winter.

TULIP AND NARCISSUS BULBS: *J. W. D.* The bulbs are attacked by bacteria, causing the disease known as "yellow stripe." No cure is known.

VIOLETS DISEASED: *Nook.* The trouble has been caused by a fungus, *Cercospora Viola*, which has been favoured by excessive dampness. Remove the diseased leaves and spray the healthy foliage and the soil with liver of sulphur at a strength of 1 ounce in 3 gallons of water. Give the plants as much fresh air as possible.

NOTES ON LILIES.

It is gratifying to reflect that the vast majority of the Lilies at present in cultivation are, for the most part, of an accommodating nature, and admirably adapted for garden culture. Only a very few, such as *Lilium Wallichianum*, *L. Lowii*, and *L. nepalense*, which are mostly of Indian extraction, demand the cultural conditions of a conservatory.

Lilium giganteum is one of the most majestic of Lilies, but its impressiveness is much more attributable to its dimensions and its foliage than to any special fascination in its flowers; it is perfectly hardy, and may be grown successfully in any sheltered garden where it finds an adequately fertile, well-drained soil. As the great bulb, after four or five years' development, becomes exhausted by the production of the immense flowering stem, it relies either upon its seed (of which there is generally a super-abundance), or its offsets, for perpetuation. The greatest plant of *L. giganteum* I have grown in my own garden, under the most favourable conditions of atmosphere and soil, was 10 feet high; but I have heard of it reaching, in other regions, a somewhat greater height.

Nothing could exceed the delicate grace of *L. Szovitzianum*, with its pendulous, purple-tipped, citron-coloured flowers. Here it nearly rivals *L. giganteum* in height; and its aspect is much more graceful and refined.

Another reliable and richly-effective Lily for garden cultivation is *L. auratum*; of which the grandest form is *L. a. platyphyllum*, the flowers being frequently 12 inches across. Writers on Lily culture often recommend that this variety should be cultivated in Rhododendron or Azalea borders, which are usually strongly impregnated

with peat, or leaf-mould; but, like the Eremuri of Turkestan and Northern Persia, it grows admirably in ordinary garden loam. The most striking variety of the *auratum* family is *rubro vittatum*, whose gorgeous colour, seen from a distance, gives it a marvellous fascination. In my own garden, owing perhaps to the influence of our humid Scottish climate, it is generally short-lived, flowering for two seasons, perhaps, and then disappearing, having lost, in that short season of retrogression, all its vitality. A very beautiful form of *L. a. platyphyllum*, almost pure white, with the faintest approximation to golden rays, is known as *virginale*. Its flowers, though not numerous, are, as a rule, of great size. The only fault I have to find with *L. speciosum* is that some of its finest varieties, such as *album novum* and *Kraetzerei* (pure white, with green bands down the centre of the flowers), come exceedingly late much later. I should imagine, than they do in Japan; and, consequently, meet with adverse atmospheric influences that materially affect the texture and fine formation of their blooms. *L. speciosum* generally succeeds admirably when planted in fibrous or peaty soil. Where perfect drainage is not obtainable it is not likely to endure. Under stagnant conditions, Lilies like *L. Krameri* and *L. rubellum* soon suffer from root decay. The former is one of the most charming of all Asiatic Lilies, but, like many other beauties, it does not last. Perhaps in a drier and sunnier climate, and in conditions, such as those which it finds among the mountains of Japan (where it was originally discovered by Mr. Kramer, at a high altitude), it might be expected to be somewhat more enduring. Nor have I found the beautiful and delicately-odorous *L. Washingtonianum*, a native of California, much longer lived. This is very unfortunate, for it is a veritable gem.

Perhaps the most enduring Lily in my garden is *L. Henryi*, which, almost invariably strong and vigorous in growth, has flowered here, in the same situation, for at least twelve years. As Mr. A. Grove has pointed out, this Lily has a lamentable tendency to bend forward when growing; and this habit is extremely difficult, if not impossible, for the cultivator to counteract. Dr. Henry has stated that the species exhibits the same characteristic in its Central China habitats. This habit often renders staking—so important for its protection in exposed positions—an utter impossibility.

The beautiful and distinctive *L. Brownii*, which also comes to us from Chinese and Japanese regions, I have had sometimes flowering exquisitely for a single season.

But many enduring consolations remain, and among these the most abiding possessions are *L. speciosum rubrum*, *Kraetzerei*, and *Melpomene*; the radiant scarlet *Martagon*, *L. chalconicum*; *L. auratum platyphyllum*, *rubrum vittatum* and *virginale*; *L. monadelphum Szovitzianum*; *L. davuricum erectum* and *incomparabile*; *L. tigrinum splendens*; *L. longiflorum Wilsonii*; the richly-coloured *L. Humboldtii*; *L. Henryi*, bending forward, like the leaning Tower of Pisa; *L. giganteum*, *L. pardalinum* and its Burbank derivatives. *David R. Williamson, Mansie of Kirkmaiden, Wigtownshire, Scotland.*

THE ROSARY.

SOME DWARF-GROWING SINGLE ROSES.

ALTHOUGH the blooms of most single Roses are rather evanescent, many of the plants produce their immense trusses of flowers in such profusion that they are objects of continual beauty. The yellow stamens are an additional charm; and, indeed, in many varieties they constitute their greatest attraction. To write upon single Roses generally would need much space; therefore I purpose only to deal with some of the best dwarf growers.

Amongst the very earliest of Roses to open their flowers are the two beautiful varieties, Austrian Copper and Austrian Yellow, both of which were in cultivation in this country in 1596, considerably more than 300 years ago. Few varieties have flowers so strikingly distinct as these: those of the first-named are of a glowing reddish copper, and those of Austrian Yellow are perhaps of the purest yellow that is to be found in any flower. Both varieties are hardy and have a grand appearance near the foot of a hedge. After their first pruning they need little removal of shoots other than those that are dead and deteriorating. It is a pity that they are not perpetual bloomers. I have seen these plants especially effective grown as standards about 3½ to 4 feet in height. Parkfever is a hybrid of this class, with scarlet red blossoms, some of which come single and others slightly semi-double. Naturally, most of the species have single flowers, and these include some very pretty Roses. But the majority are apt to grow too strong for ordinary purposes. Another dwarf variety that flowers early is *Altaica*, with fairly large, lemon-white blossoms, much resembling those of the Scotch Briar and producing black berries in the autumn. The pretty yellow Abyssinian Rose, *Ece* I have had very early in bloom. *P. unifera* has single, bluish-tinted blossoms that are followed by large, scarlet hips. Another desirable class of this type of Rose is the *Wichuriana*, which develops blooms in clusters from July until frost appears. Although a vigorous grower in its natural state, it creeps closer to walls and other surfaces than any other Rose.

Then there are various sorts of *Rosa rugosa*, *alba* being one of the best white varieties, whilst *Rose Apples* has pale, silvery-rose flowers, these being followed by large hips. With me, *Atropurpurea* is a single Rose, but I note the raiser describes it as "very double." My plants are true to name and bear very showy hips after their intensely, blackish-crimson buds and deep-mauve flowers are over. The *rugosa* Roses are rather strong growers, and frequently form bushes as broad as they are high. *Maharajah* is a very large flower with me, seldom other than single; it has very deep, velvety-crimson petals and showy anthers. A much shorter grower is found in *Irish Engineer*, which is one of the most brilliant scarlet Roses. The series of single Roses sent out by Messrs. A. Dickson & Sons, all prefixed by the name *Irish*, are amongst the most beautiful in cultivation. I would give the palm to *Irish Elegance*, which is one of the most decorative of Roses: the blooms are tinted with bronzy-orange and scarlet in the bud, and become tinged with apricot as they expand. The plant is a good grower, and produces grand spreading trusses from late June until October. *Beauty* is a large, pure-white-flowered variety of good habit, and constantly carrying large trusses of blooms. I consider that *Engineer*, *Elegance* and *Beauty* are the three best varieties of the series. *Stella* and *Leuchtstern* are two varieties that do not quite form climbers with me, and, as they last so long in flower, especially *Stella*, I name them. Both are of a deep rose colour, with lighter centres, *Stella* being the brighter. The hybrid Sweet Briars are difficult to omit from my list, but as they grow as strongly as any of the so-called climbers I will only mention them in passing. Paul's

Royal Scarlet is aptly named, and is especially good late in the season, when many of the single Roses are over. Lady Curzon would appear, from its thorns and foliage, to be a hybrid of *R. rugosa*. The flowers are of a beautiful pink colour, and are very freely produced for some time in July. The buds of this Rose, if cut when quite hard, will travel well and expand better than those of any other variety with which I am acquainted. Mrs. O. G. Orpen, a single Damask Rose, should not be omitted, although it is a strong grower. The bright, rosy-pink flowers, with their prominent, golden anthers, make the variety valuable for decorative purposes. It has been awarded the Gold Medal of the National Rose Society. *A. Piper.*

ORCHID NOTES AND GLEANINGS.

BRASSO-CATTELEYA VILMORIANA.

We remark your note on p. 98 respecting *Brasso-Cattleya Vilmoriana* (*Cattleya Mossiae* × *B. C.* Mrs. J. Leemann), exhibited on January 26 by Monsieur Maron at the meeting of the Société Nationale d'Horticulture de France. We beg to say that we presented the

THE MARKET FRUIT GARDEN.

COMPLETION OF PLANTING.

FEBRUARY ended with a heavy rainfall, which brought the total for the month nearly up to average, whereas there had been a happy deficiency up to noon on the 22nd of the month. Therefore, although March opened with brilliant weather, the land was in very wet condition for any arrears of planting that were left. They could hardly be considerable, as there had been six weeks of generally dry and frequently sunny weather up to the time named above. My own measurement of rainfall for that period was a little under $\frac{3}{4}$ inch, and there was hardly a day when planting could not have been done well after the effects of the very heavy downfall of the first 12 days of January had subsided. Allowing a week for this, we had an almost uninterrupted period of five weeks, in which a great amount of planting could be got through.

CUTTING BACK YOUNG TREES.

Planters have now to decide which of the two opposed policies they will adopt in reference to trees set out during the current planting season, that is to say, whether they will cut them

in such a case is entirely wasted, for, unless the trees are to be permanently stunted, the young branches must be cut back below the fruit-buds in the second season. That is to say, they will require to be cut back as near the trunk in the second season as were those that were treated in the season of planting.

The weaker the habit of growth in a particular variety, or in the individual tree, the more severe should be the cutting back, and the more important it is to perform the operation in the season of planting. Similarly, the poorer the soil, the more necessary are severity and promptness in this work. Where trees that were fit to be planted at all have failed to start well after having been cut back in the first season, the reason, as a rule, is that they were not cut back severely enough. Never have I had reason to regret having exercised great severity in this operation in the first or second season, whilst I have often had reason to regret insufficient severity. As stated on a previous occasion, I tried the plan of deferring cutting back to the second season with one row of Lord Grosvenor planted four years ago, and the result was the formation of fruit-buds on almost the whole length of each of the young branches left

FIG. 66.—*CYMBIDIUM LANGLEYENSE* (VEITCHII): COLOUR OF FLOWERS GREENISH-BROWN WITH A BLOTCH OF REDDISH-BROWN ON THE LIP.

same hybrid at the meeting at Brussels on January 14, under the name of *Brasso-Cattleya amabilis*. The plant received a certificate of merit *par acclamation*. Having thus named our plant 12 days before Monsieur Maron presented his, we consider that the first name should be maintained. We exhibited at the last meeting at Brussels (February 19) *Cypripedium Glaucosigne* (*C. glaucophyllum* × *C. insigne* Harfield Hall var.). The plant received a certificate of merit. *Th. Pauwels et Cie.*

CYMBIDIUM LANGLEYENSE (VEITCHII).

THE hybrid illustrated in fig. 66 is from a cross between *C. Lowianum* and *C. Devonianum*, being the first hybrid we remember from the latter species. Messrs. Jas. Veitch & Sons, the raisers, exhibited a plant at the meeting of the Royal Horticultural Society on the 28th ult. This plant bore a spike with 14 flowers. The sepals and petals are of a greenish-brown colour, and the lip is marked by a blotch of reddish-brown. This new *Cymbidium* received an Award of Merit under the name of *C. Veitchii*, but that name being already in use in the *Orchid Study-Book* for a hybrid from *C. eburneum* and *C. Lowianum*, the raisers have determined to call the present plant *C. langleyense*.

back in this month or in April, or leave them uncut for another year. The controversy upon this point is as lively as ever, and probably it will be perennial. For my own part, theory and experience alike induce me to adhere to the old plan of cutting back in the season of transplanting. Theory teaches that the damage done to the roots in transplanting should be balanced by a reduction of the tops of the young trees. The opposing theory is to the effect that, until the roots of a tree are well established, they are not in a proper condition for stimulating the growth of the branches which are to furnish the tree; and that if the shoots are left entire for the first season, their call upon the roots stimulates the growth of the latter, and fits them for the full nourishment of the tree in the succeeding season. This reasoning seems to me to be fallacious. The shortened roots, I contend, are better fitted for nourishing fresh wood than for feeding old wood. Their failure in the latter object is often shown by the premature formation of fruit-buds upon the uncut branches of the young trees. There has been unavoidable root-pruning in the course of transplanting, and the usual result of root-pruning is apt to follow when trees are left entire for the first season. The energy devoted to the development of fruit-buds

entire; whereas the trees of the same varieties in adjoining rows formed strong new growth free from fruit-buds. It was necessary to cut back the former to mere stumps, in order to get wood growth, and if the variety had been a feeble grower, like Lane's Prince Albert or Golden Spire, it might have been impossible to find a wood bud on some of the branches. At present, the experimental trees are about equal to those cut back in the first season; but if the latter had been treated with the same severity in the first season as the former were in the second year, they would probably be now the better furnished and more vigorous trees.

USE OF TIES IN TRAINING APPLES.

In training young Apple trees of some varieties tying will often conduce to the symmetry of the trees. Perhaps some critic may say that the correction of mis-shapen or misdirected growth should be effected entirely with the knife; but this cannot be admitted, although it is true that much unshapeliness is due to insufficient force thought in pruning. Some varieties, such as Lane's Prince Albert and Beauty of Bath, send out shoots diverging too widely from the main branches, and pointing in a direction parallel with the ground level. This tendency, moreover,

is intensified as soon as the trees bear fruit by the weight of the crop. To correct it merely by cutting back severely to an upright bud would often be to sacrifice substantial growth and fruit that is about to be produced upon it. On the other hand, tying an erring shoot to a strong interior branch, or to another shoot diverging in the opposite direction, drawing them towards each other, will put the growths in proper shape, while preserving the sturdy portions of them. A very little drawing in of a divergent shoot will alter the pitch of it. In many a case a wide gap on one side of a tree may be filled by drawing together branches on either side of it, at the same time relieving those sides from crowding growths. Of course, the tying must be done with loops, to avoid girdling the branches. Moreover, it is not recommended that the tying-in of weak shoots should be substituted for cutting them back to buds pointing in the right direction, or for spurring them. The advice as to tying relates to substantial growths only, and to such growths only where there is plenty of room for them. Where horse-cultivation between the rows of trees is practised, some tying-in of shoots and branches that would be injured by the implement used or the harness of the horses is often the only alternative to their sacrifice. The same remarks apply to the Victoria Plum. *Southern Grower.*

CHRYSANTHEMUMS.

SOME OF THE NEWER VARIETIES.

NOVELTIES put into commerce during 1910 include some first-class varieties, and probably a dozen of them are suitable for showing in the keenest competitions during the coming season. A description of the habits and other qualities of the flowers may be found useful to intending exhibitors.

WHITE QUEEN is probably the best white Japanese variety, although, in the south, the blooms develop very early. The plants are of medium height, strong, healthy growers, flowering naturally on second crown buds. The large blooms possess florets of hard texture and enduring qualities.

GEORGE HEMMING has blooms of a distinct colour—a bright, purplish amaranth. The flowers "finish" well, the central florets standing erect. The plant is a tall grower, and, with us, flowered on first natural crown buds, but the hoots may be stopped early for blooming from second crown buds.

MARY FARNSWORTH is best rooted late and flowered on first crown buds. The plant is of a medium height, and a healthy grower, the flowers being broad shouldered and composed of very broad florets. The flowers are of no value when developed from any other than first crown buds.

HENRY POULTON is remarkable chiefly for the extremely long florets of the flowers and consequent large size of bloom. The colour is a deep narrow-crimson. The plants need to be stopped early in spring, and allowed to develop second crown buds, otherwise the variety is too early for exhibitions. The plants are slightly above the average height, and the growths are wiry.

SIR ALBERT ROLLIT is a large flower, of broad shouldered, reflexed form. The florets all show the reddish colouring, lying flat and compact. The plant is a healthy grower, with splendid foliage, and, like many other varieties, the blooms develop too early on first natural crowns, hence the shoots must be stopped in April for second crown buds to develop.

SHANKLIN SUNSHINE.—This is one of the best all-round Chrysanthemums, flowering naturally on second crown buds. The plant is a robust grower, and of dwarf habit, whilst the blooms are of good substance, with hard florets, that de-

velop even to the centre. The plant may be allowed to grow very strongly without fear of damping.

MRS. ROBERT BROWN.—In its long, broad florets, this variety is probably unequalled. It flowered with us on first crown buds about 5 feet high, the plants, weakly at first, growing strong and robust after the first break. The colour of the flowers is yellow suffused with chestnut.

FRANCES JOLLIFFE is a grand variety that flowers on first natural crown buds. The plant is of a medium height, and a free, healthy grower. The broad, deep blooms are remarkably clean and fresh in appearance.

MRS. F. C. STOOD.—Although rather a tall grower, this is a useful variety, the blooms being of a lovely form and distinct in colour. It is best stopped early, say, mid April, to obtain second crown buds.

MARY POULTON.—This proved a weakly grower in its younger stages with us, and the plants were finally potted in small pots; but the blooms are of a beautiful form, and of a lovely shell-pink colour. The plant should be stopped in April, for second crown buds, but it is a dwarf grower.

MRS. W. TIGGLEN is a sport from Mme. G. Rivoil, and is quite equal in point of merit to its parent, and also to Mme. P. Radaelli.

EMPRESS.—This variety also grew weakly up to the final potting. The flower is of a perfect incurved form, but lacks a sufficient number of florets to make a good exhibition bloom flower. It will, however, be tried again next year, as it has a striking and massive appearance. The colour of the florets is yellow.

CAPTAIN MITCHELL should also be taken on the first crown buds, but rather early; as an experiment, some of the plants might be stopped very early. The plant is a dwarf and sturdy grower, producing large, reflexed flowers of a rich rosy-purple colour.

BESSIE G. PAYNE is a somewhat unique grower, being very sparing of foliage, and with particularly wiry shoots. The florets are hard in texture, the flowers are large and last well. Cuttings may be rooted late for first crown buds to develop, or perhaps it would do best if stopped in April for second crown buds.

A few of the best of the older sorts are as follows:—

HON. MRS. LOPES.—The finest of yellow Chrysanthemums when obtained in good form, but the blooms are often shallow. Cuttings should be rooted early and well matured. We had a fine flower developed on a single-stemmed plant that was potted late, and flowered on the first bud that came.

MASTER JAMES. This variety develops grand blooms on first crown buds. It should be rooted late, and stood at the exposed end of the rows in summer-time. The flowers require an exceptionally long time to develop fully, but they are of splendid quality when properly finished.

LADY LEITCHWORTH.—A beautiful though rather early yellow Chrysanthemum, rather prone to show damping in the petals in patches. The cuttings should be rooted late in the season to flower on first crown buds.

W. MEASE.—One of the largest flowered varieties, but of no particular beauty of form or colour. It should be bloomed on second crown buds.

GEO. J. BRUZARD.—A flower of incurved and interlaving form, but of broad-petalled, massive style. The plants should be stopped very early, to develop second crown buds.

MISS A. NICOLLS.—A pure white sport from W. Jinks.

RECENT NOVELTIES.

Amongst others, the following novelties were exhibited exceptionally well during the past season:—

JAPAN.—A deep-yellow, incurved, Japanese

variety, with a tinge of red on the edges of the florets.

MIKAGO.—A large, deep flower, of rose colour.

RED CHILL.—A large, reflexed variety, with broad florets.

D. B. CRANE.—Yellow, shaded with bronze.

MAUD WILLIAMSON.—A large, reflexed flower, of the best exhibition type.

VICTORIAN.—A Chrysanthemum of compact and pleasing form, the colour being a deep bronze.

MRS. GEO. HARTMANN.—A perfectly round bloom, and chestnut-red in colour.

R. C. KELLY.—A large flower, of fine, incurved form, the colour being a dull amaranth.

MRS. R. A. WITTY.—A crimson variety, of large size, and with broad florets.

COUNTESS OF GRANARD.—A yellow Chrysanthemum, heavily shaded with reddish-buff, after the style of Shanklin Sunshine.

A SELECTION OF THE OLDER VARIETIES.

The following are well-known and excellent varieties:—Reginald Vallis, Splendour, Mrs. F. W. Vallis, Mrs. A. T. Miller, Bessie Godfrey, W. Jinks, F. S. Vallis, Edith Jamieson, Mrs. C. Penford, Mrs. L. Thorn, J. H. Silsbury, and Lady Talbot. *P. P.*

NOTICES OF BOOKS.

THE CHARM OF GARDENS.*

A GARDEN may have charms other than those that appeal to men interested in plants and flowers, or in effects and design. There are garden ghosts and garden saints, memories, associations, the thoughts that come as one walks or sits among the trees and flowers. Mr. Calthrop's book deals entirely with the sentiment of gardens and the historical sense of them, and avoids the more prosaic practical side. He has done it extremely well. Readers who can appreciate the writings of Richard Jefferies, Alfred Austin, Ruskin and Wordsworth will find Mr. Calthrop's book to their liking. Some of the chapters might be called thoughts by the wayside, and suggest whiffs of country air. Here, for example, is a passage redolent of the country:—"As I sat on my stile I felt this was all mine; no person knew the beauty of it as I did. No one but I saw the field of Oats laugh, or cared to note the business of the dragon fly, or the flashing patterns of the butterflies. I had seen these fields turned up, rich and brown, under the plough, and tender green when the seeds came up, and waving green, and gold when they bore their harvest of Corn, or silver and green with roots and red with Beets. I had counted the sheep on the hill sides, and watched the cattle stray in a long line to be milked at milking time, and though I did not farm an acre of it, I owned it with all my heart, and gathered its harvest with my eyes. Every field footpath had its story, the road was rich in old romance, and hidden by the trees at the head of the valley was the big house where my hostess lived, and with a loving hand directed all this little world—but I doubt if she owned it more than I."

The story of the itinerant tailor who grew tired of sitting cross-legged on a bench and went out and about to see the country lanes and cottage gardens, sewing only in winter, is a delightful episode. "There are men who find the whole of Heaven in a grain of Mustard seed; and there are those who, in all the pomp and circumstance of a hedge of Roses, find but a passing pleasure to the eye." The Roman Gardener in England; St. Fiacre the Patron Saint of Gardeners; A Lover of Gardens; The Olympian Aspect; these are the headings of chapters full of fine thinking. *Kalendarium Hortens.*, or the *Gardeners' Almanac*, 1664, follows a discourse on John Evelyn, the author of the *Kalendar*, and should be read

* By Dion Clayton Calthrop. (A. and C. Black.) Price 7s. 6d.

by every gardener who thinks there was not much good gardening in this country 300 years or so ago.

The chapter on town gardens is one of the best in the book. But Mr. Calthrop's gardens are chiefly in Piccadilly Circus, Oxford Circus, and those other central spots where the flower sellers congregate with baskets of Roses, Violets, Carnations, Daffodils, Anemones, &c. They are, he says, a perpetual flower calendar and reverence is due to them. They keep the grey, desolate winter alive with bright, sweet-smelling flowers. "A curious race, untidy, with a screw of hair twisted up under a battered hat of black straw, with faded shawls wrapped round them, and the weapons of their craft arranged about them—jam jars of water, wire, bast, rows of little sticks, on the ends of which buttonholes are stuck. . . . They have a certain dingy dignity, as of Lichens on the pavement."

There are some shocking mistakes in the spelling of the plant names, but the author is clearly not a man for labels—"let him name it who can, its beauty remains the same." Finally, we have to speak of the illustrations, of which there are 32, full page and coloured. They are charming little pictures of garden and woodland scenes, somewhat overdone perhaps, but they serve their purpose, which is that of an appropriate setting to the author's fine writing, the effect of which they heighten, as the elaborate scenery in a modern theatre does a play. The book is crown quarto, handsomely bound in cloth, the paper and type are good, and there is a fine broad margin. W.

A JOURNEY TO JAPAN.

(Continued from p. 117.)

A SMALL part of the island is devoted to herbaceous plants, annuals, and shrubs. *Gardenia pelenkahuana* has wonderful, bell-shaped blossoms; *Posoqueria longiflora* develops exquisitely-scented, white flowers, 6 to 8 inches long, and with a corolla 2 to 3 inches broad; *P. multiflora* has similar flowers, but broader leaves; *Ixora timorensis* develops a mass of very small, white flowers on a long thyrse, and is also finely-scented. Other interesting plants are *Randia maculata*, the flowers of which are white, with violet on the outside, and 10 inches long; *Oxyanthus tubiflorus*, with long, yellowish flowers; the star-like single-flowered *Gardenia florida*; *Cassia alata*, with trusses of orange and yellow blossoms; *Plumeria alba*; *P. acutifolia*, which are often found growing near Indian temples; *Isotoma longiflora*, with white, star-like flowers; many fine Hibiscuses; *Tithonia diversifolia*, a yellow composite which has spread all over the country; *Cesalpinia pulcherrima*, with yellow and orange flowers; and *Brunfelsias*, with white, blue, or yellow blooms. The flowers most prized by the Javanese are those of *Michelia Champaca* and *Jasminum Sambac*. *Aglaia odorata* and *A. odoratissima* are shrubs with very sweet-scented, small, yellow flowers. They are planted in the native gardens, as are also *Saraca declinata*, *Gardenia florida*, and *Poinsettia pulcherrima*.

The Orchid garden at Buitenzorg is sheltered by a tree of *Cephaelis (Evea) borbonica*, which bears scented, yellowish fruit. The bark is very rough, and *Grammatophyllum* grows on the stem. Some of the pseudo-bulbs of this Orchid are 3 to 5 yards in length. Thousands of flowers are developed on a single plant, which sends its roots over the tree to collect the necessary food. All over the Orchid garden, in regular lines about 1 yard distant from each other, are small trees of *Plumeria acutifolia*. Only a few branches are left at the top of each tree, and on all are planted some kind of Orchid. The collection comprises inconspicuous as well as large-flowering species. *Dendrobium crumenatum* abounds on nearly every tree and shrub. Palms and conifers are covered with it. In Ceylon I observed the plant in flower on April 7 and in Buitenzorg on April 23

and May 26. In certain localities all the plants of *Dendrobium crumenatum* flower at the same time, every four to eight weeks; and all the flowers open in the forenoon, some a little earlier and some a little later than others. The pseudo-bulbs are sometimes 1½ yards long; they branch freely, and the plant forms large masses. Plants of *Juniperus funebris* and *Podocarpus* are sometimes covered with this lovely Orchid in flower. The same evening all the flowers fade, and not a single flower-bud is left to open the next day. Other Orchids are also plentiful on wild trees. One of the least showy, but most interesting, is *Tamiophyllum*, which does not produce foliage, the green, flat roots, which grow over the mossy bark, performing the functions of the leaves. The small, yellowish flowers are produced on a small stem near where the roots originate, and the seed-pod is nearly as heavy as the whole plant. *Cattleyas*, *Cyrtopodiums*, and some other Orchids, especially those which require a dry season at times, are grown under glass roofs. Terrestrial Orchids are planted in beds. *Spathoglottis* are especially plentiful in private gardens in the neighbourhood, where they flower freely in large pots. *Phalenopsis* also suc-

ceded very well, and the plants flower freely on trees of *Cinarrum* planted as an avenue by Teysmann (see fig. 69). Every tree in this avenue bears some fine or rare climber. *Pothos aureus* surpasses all creepers by its luxuriant leaves, which are very large, and split like those of *Monstera deliciosa*. The branches which attach themselves to a neighboring tree, have only very small leaves, but as soon as they reach their objective they form large leaves again. *Philodendron panduriforme* has leaves of a very peculiar shape; *P. sagittifolium* ascends very high up the trees, whilst *Scindapsus Treubii* sends down its slender stems from the highest branches. Interesting *Gnetums* cover several large trees, and *Previnetia strobilacea* adorns the avenue with its red flowers, giving food to flying foxes which, whilst feeding on the fleshy flower, pollinate it. *Agaves* and *Yuccas* makes fine specimens in these gardens, and *Bromeliads* grow freely under the shade of the Tree Ferns and Cycads. *Nymphæas* are plentiful, these being mostly hybrids of *N. Lotus* and *N. rubra*. The flowers are of a remarkable size, and the colours range from white to dark red. I discovered an undescribed species of the Australian *Anechya* section

"ROCCA LONGA."

I AM determined to call this article *Rocca Longa*, in inverted commas. I gave fully-named stations for *Saxifraga florulenta* because, though that plant is a king of rarities, it is very abundant in its district, and that district is remote, high, hard and expensive to come at. And, finally, *Saxifraga florulenta* will never be a gardener's plant. The case is entirely different with *Daphne rupestris*; though its few stations are as far, nearly as high, and even more difficult to come at than those of the Saxifrage, it is yet a plant of such habits, beauty and popularity that the unscrupulous would gladly go and strip its native cliffs if I named them too openly. But those who are adepts in Alps, those who can be trusted, will know well what I mean by *Rocca Longa*.

FIG. 67.—VIEW IN THE BUITENZORG BOTANIC GARDEN SHOWING THE PLANT-SHELTERS WITH OPEN SIDES AND ENDS.

Rocca Longa is a lonely high ridge of limestone, a very long way from any place that anyone has ever heard of. This is as well; for it is prodigiously rich in rarities. In earliest August, in the stone slides at its feet, exactly like the screes of limestone under Ingleborough, *Cyclamen europæum* is glorious in bloom, and everywhere, in all the bosage, are the great leaves of *Helleborus niger*. One climbs and climbs and climbs: the rocks are full of *Phyteuma comosum*, and among the shrubs are *Lilium croceum* and *Genista radiata*. Higher still begin the *Primulas*—*Auricula spectabilis* and another—*Auricularia*, but dark green, that I cannot yet name. Then there are a few pieces of *Saxifraga mutata*, *S. aizoon* among *Primula viscosa* on rocks, and *Cephalanthera rubra* on a high open shoulder. But this is only the preliminary Alp. We have yet more climbing before we reach the Col, where there is an enormous assemblage of cows, and a farm.

Then, for the first time, do we actually see the *Rocca*—it is a terrific, jagged rampart of limestone, far away in the distance and awfully high. However, the path continues till it reaches the base of the ridge, then mounts leisurely, at a gentle slant, round each successive buttress of the

Then, for the first time, do we actually see the *Rocca*—it is a terrific, jagged rampart of limestone, far away in the distance and awfully high. However, the path continues till it reaches the base of the ridge, then mounts leisurely, at a gentle slant, round each successive buttress of the

mountain. The vegetation here is a light, very low, alpine scrub, in peaty humus. *Saxifraga caesia* begins to occur on the rocks, and becomes increasingly abundant as one goes—tiresome thing, because one wants *S. tombeanensis*. But a foreign collector is supposed utterly to have exterminated *S. tombeanensis* on the Rocca. In another instant there is a big flash of crimson among the sparse and pallid *Rhododendrons*: it is *Silene Elizabethæ*. Queen Elizabeth's *Silene* does not grow in hot shale-slides as reported, but on rather cool exposures, in a limy soil full of chips. On the north side of the Rocca it is frequent here and there in such rocky inclines, and down below, in the Val Riario, it seeds abundantly on the

the end, we reach the little cowshed called the Casa della Rocca (or, in French, the "Refuge d'Arlet"). This sits in a hollow beneath the peak itself, and, just beyond, a scramble up the slope brings us under the great, rosy cliff which is the one home of *Daphne rupestris*. Neither to the right of this cliff will you find it, nor to the left; though the most precious of plants occurs again here and there in the district, it is almost uncannily local in its distribution; you will not see a sign of it on the precipice next to the one on which it abounds, though they are identical in aspect and formation.

In another moment the bitterness of years is wiped out; there on its cliff shines that *Daphne*,

yard, up and up to the very summit of the stark precipice, in places, mercifully, far beyond reach of the depredator. Not that the *Daphne* has not its own methods of dealing with the depredator. The rock is sound and hard as iron: no light labour, nothing short of hammer and coal chisel, wisely wielded on favourable chinks, will get you out sound pieces. (But the depredator has a foul habit of tearing the treasure out rootless, and thus killing alike what he takes and what he leaves. I have suffered under this habit of his almost as much as the *Daphne*.) The plant was only in flower on the highest cliffs when I saw it: up in inopprobrious places these exquisite rosy trumpets were still lying firm and flat on the flat, firm matting of foliage. Will it ever do thus on my cliff? It is thriving there, but a rabbit has just eaten the best plant down to the ground. I am in hopes, though, that it will think it has only been cut back. I saw no sign of any seed: old plants send up suckers, far away, out of some apparently unconnected cranmy.

All that slope of cliff and grass is agog with rarities. Here is *Mehringia glauco-virens* in the chinks; *Primula Auricula*, *P. spectabilis*; and, in dark hollows sheltered from moisture, that priceless marvel *Saxifraga arachnoidea*. This had been glorified to me, as a golden glow of flowers, above its tussocks of silver-fluffy leaves; and I found it to be the dowdiest of little pale weeds, flimsy and annual in appearance. I believe it to be perennial, however; though nearly impossible to cultivate. I have not got it, and I do not mourn it. But for this disappointment, I was soon indemnified, by rediscovering, on one isolated inaccessible pinnacle, several tufts of the best *S. tombeanensis*. This lovely little *Saxifrage*, close to *S. dapsenoides*, takes its name from the Cima Tombea in Southern Austria; and *Daphne rupestris* also occurs, as well, on the Cima Tombea. They seem to hunt in couples.

I have not left myself much room to tell of the Col d'Arlet, just round the corner, over which we have to make our way down into the Val Riario, and so, to the Lac d'Azur. All the Col, like all the Rocca, is of limestone; on the south side are masses of *S. caesia* and *S. mutata*, among which anyone may have the luck to collect—i.e., adventitiously—*S. Hausmanni*. And as soon as we are over on the shady northern slope begins the reign of *Ranunculus crenatus*, which abounds all down the white scree, under cliffs full of *Phytoloma comosum*. This rare Alpine Buttercup is a twin to the perfect *R. alpestris*, except that the glossy leaves are rounded in outline, with slight crenulation, and the petals are so much more deeply "echinaceous" that the flower, instead of being a snow-white circle like that of *alpestris*, is more nearly a tiny pure white Dog Rose. If I dared, I would say that *R. crenatus* has an even more fairylike loveliness than *R. alpestris*. And it seems to be quite as easy and unexacting in its wishes as even that most easy-going of all mountain plants. But I have such a craze for the white high Alpine Buttercups, that I dare not give rein to it. So I will only add that on the way down we despise acres of what M. Corveon has justly called "cette maudite" *Daphne striata*, and then come to a long stop among the innumerable royal *Silenes* by the dried-up bed of the Riario. *Reginald Farrer.*

FIG. 68.—THE BOTANIC GARDEN, BUITENZORG, JAVA: THE CANARIUM AVENUE WITH CLIMBERS AND EPIPHYTES.

shingle of the river-bed, and is everywhere in the rubble. I had no idea that a magenta-crimson flower could be so splendidly beautiful.

At last we come to the summit of the ridge, and the track now crosses over and leads along the turf slopes on the southern side of the Rocca. That turf is almost entirely composed of *Primula spectabilis*, in solid tufts all along the mountain side, interspersed with the brilliant blue of *Linum austriacum* (much more brilliant than *L. alpinum*) and matted with *Gentiana Clusii*. In open, stonier patches there is *Viola heterophylla*. What this ridge is like in flower-time I dare not begin to imagine. So, in

in cushions like a tiny *Globularia cordifolia* *Daphne rupestris* is wholly different from the rest of the family in its habits. It is purely a saxatile plant: as purely saxatile as *Androsace imbricata*. It grows from microscopic crannies of a sun-baked limestone cliff (and tolerates no variation of this sunny southern aspect), where you would think that nothing living could find sustenance. And from these fine rifts of the rock it spreads out its growth tight, tight against the precipice, tighter than any Willow or Cotoneaster. It will not grow anywhere except in this full exposure to the south: it has virtually no soil except a little humus. Yet here it is, by the foot, and by the

DAVID DOUGLAS.—A biography of this famous gardener and plant collector is contributed to *The Transactions and Proceedings of the Perthshire Society of Natural History* for 1909-10 (vol. v., part ii.), by Mr. R. Dow. DOUGLAS will be best remembered as the introducer of the Douglas Fir, *Abies Douglasii*, but he also enriched our gardens with *Abies nobilis*, *A. amabilis*, *Pinus Lambertiana*, and other Conifers, as well as useful flowering plants, such as *Clarkias*, *Calochortus*, *Penstemon*s, and *Eschscholtzia*. His plants were described in Hooker's *Flora Boreali-Americana* and in the *Botanical Magazine*.

The Week's Work.

THE FLOWER GARDEN.

By R. P. BROTHURSTON, Gardener to the Earl of Haddington, K.T., Tynningham, East Lothian.

CLEMATIS.—Some kinds of Clematis, such as *C. Jackmanii*, should be pruned now, but the shoots should not be cut too severely. *C. viticella* and the large-flowered varieties of *C. lanuginosa* will need pruning to induce the formation of spurs. *C. vitalba* is often allowed to grow unchecked, but far better results follow when pruning is practised, shortening back the side growths, though not the main or leading shoots. *C. montana* and its variety *rubens* flower in the early summer, and their pruning should not be performed until after they have flowered. *C. Davidiana* usually needs to be cut to the ground level, but, owing to the mild winter, many of the shoots are alive for a considerable distance, and if these are shortened to the buds nearest the ground, the plants will flower earlier and give a longer display of bloom than usual. *C. recta* is a beautiful herbaceous species that is propagated from seeds: the feathery appendages to the fruits form an additional attraction after the flowering is over. The Clematis often dies from no apparent reason, and I am inclined to believe that if the plants were propagated from cuttings instead of grafts, the trouble would not be experienced to so large an extent.

ROSES TRAINED UPON WALLS.—These need not remain unpruned any longer. In my own case I commence pruning very early in the new year those trained on hot-house walls, and in this way obtain very early blooms. It is possible to be too cautious in the pruning of climbing Roses. Plants are frequently to be seen in a debilitated condition, and flowering sparingly owing to the pruner having left upon them too much old wood. In such cases the older growths should be cut down to nearly the ground level, leaving a limited number of the stronger growths. Roses growing upon trellises and posts should also have all superfluous wood cut out in autumn, therefore at this season all that is required is to shorten the shoots, cutting back those which are weakly. The *Wichuraiana* hybrids are so hardy, so floriferous, and so late flowering that we are substituting them for other kinds. In some gardens I observe that the *Wichuraiana* hybrids are allowed to grow without restriction or pruning, but this is sure to result in the need for extra severe pruning at a later date, which is not a good practice. At the same time *Wichuraiana* Roses should be pruned less severely than other climbers, their small leaves allowing of many more shoots being trained in than is practicable on most other Roses. We are still cultivating *Reine Olga de Wurtemberg*, *Alister Stella Gray*, which needs much thinning out, the old *Aimée Vibert*, which flowers both on last year's wood and that of the current year, and *Blush Rambler*. So long as climbing Roses appear vigorous stimulants should only be afforded after careful consideration.

THE "MIXED" BORDER.—It is quite time to decide how to furnish the spaces which occur between the perennials in the herbaceous border. In settling this question, the season at which it is desired to have the best display of the year must be borne in mind. If it is in July and August, then such plants as Sweet Williams need not be replaced, but if the display is to continue through the autumn, then it is essential to provide a very varied selection. Again, instancing Sweet Williams, these should be planted wide enough apart to permit of later flowering subjects being interspersed among them. The plants for thus mixing with the Sweet Williams include such species as Scabions, tall Delicias, Gladioli, and such annuals as *Clarkia elegans*. Plants which are extensively employed elsewhere should not, as a rule, be planted in a mixed border. If intermediate Antirrhinums are made a feature in the formal garden, I would have very few or none in the mixed border, though taller growing Antirrhinums might very well be used in this latter arrangement. A mixed border permits of an inclusion of a large variety of interesting and gaily-

coloured plants, especially if perennials are arranged to occupy the back of the border, making exceptions in cases of less tall-growing plants such as *Anemone japonica*, *Rudbeckia speciosa*, *Papaver rupifragum*, and *Aster cordifolia*, which must be planted nearer the front. Sweet Williams, *Lychnis coronaria*, the white and blood-red varieties of *Violas*, and similar plants should be planted out at once. A mixed border planted with species which flower in succession during the greater part of the year cannot be kept gay unless other plants to succeed those which flower early are kept in reserve. Such plants as herbaceous Phloxes, perennial Asters, and annuals are very useful for the purpose. At the same time never allow a mixed border to be degraded until it is made a kind of receptacle for all the odds and ends left over from planting in the other parts of the grounds, or for receiving the refuse from the greenhouse. If the scheme is worked out thoughtfully, it may be so arranged as to provide one of the most pleasant features in the gardening year.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. Holford, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

PHALANOPSIS.—There are no Orchids more handsome than these, and very few more difficult of cultivation, especially in some establishments even though they get every care from skilled cultivators. Where a large collection is maintained, it will be found most convenient to devote a house especially to them, but in the case of a few plants only, they should be placed together in one part of the warmest division. The plants require an abundance of moisture in the atmosphere at all seasons, whilst water at the roots must be applied with great discretion, especially during the winter. Excessive moisture in the latter direction, improper temperatures, and imperfect ventilation are the sole causes of the dreaded spot in the leaves. During the winter, from November until March, a temperature of 65° to 70° by day, and 60° to 65° at night is sufficiently high, but during the remaining portion of the year the temperatures may range from 65° to 70° by night, rising to 75° to 80° by day, or even more with sun heat will be found to suit them best. These temperatures should be maintained with a free circulation of air, weather permitting, and the atmosphere should be well charged with moisture. It is essential that close attention be paid to shading, as few Orchids are more liable to injury from the sun's rays. *Phalenopsis* should be grown in baskets suspended from the roof rafters, and the leaves should not be nearer than 18 inches to the glass, in order that they may not suffer from sudden atmospheric changes. These plants generally commence making new roots during the present month and the work of affording fresh rooting material to those requiring it should receive attention immediately root action is observed. Healthy, established plants with their roots clinging firmly to sound receptacles should not be disturbed beyond removing the old rooting material. Carefully pick this out from amongst the roots, then make the drainage good and fill up anew. Those in need of fresh receptacles should have old material and drainage removed, and be carefully taken out of their pots or baskets by detaching any clinging roots with the aid of a thin-bladed knife. Following this operation, select for each plant a suitable sized basket, and afford perfect drainage, working this in carefully amongst the roots. A good rooting medium for *Phalenopsis* consists of *Osmunda* fibre two fifths, *Sphagnum* moss two fifths, and *Polypodium* fibre one fifth, broken up and well mixed together. This compost should be pressed firmly amongst the roots, finishing off the surface with a thin layer of clean-picked *Sphagnum* moss.

SELENIPEDIUM.—The present is a very suitable time to examine *Selenipediums*, when roots are pushing forth from the younger growths. These plants always give the best returns when they are root bound, therefore healthy specimens should not be disturbed, otherwise than by having the surface material removed and new material added. Should repotting be necessary, it is advisable to give a liberal shift, so that further root disturbance will not be needed for some time. Large specimens that are in a bad condition at the roots are best broken up and

potted separately, it being much more satisfactory to cultivate young plants than to make up large pots from small pieces. Let the pots be clean, and well provided with material for drainage, covering the latter with a layer of thin turf. The compost used may be similar to that advised for *Cypripediums* in a recent calendar (see p. 54), using this in as rough a state as practicable, with a liberal sprinkling of finely-broken crocks and coarse silver sand. The compost need not be pressed too firmly, but just firm enough to secure the plants, as the roots run more freely when the materials are not too close, and the amount of water they require soon settles it. *Selenipediums* when healthy may be watered liberally, even just after repotting. If roots are plentiful, they require inspection almost daily. A shady position with an intermediate temperature should be afforded these plants, and if the atmosphere is kept moist and the plants lightly sprayed over in hot weather insects seldom attack them, but should any put in an appearance they must be removed at once by the usual means.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Aston Clinton Gardens, Buckinghamshire.

PROTECTING FRUIT BLOSSOMS.—The fruit-buds on almost all the trees are numerous and strong, and if they escape injury by late frosts, there is a good promise of an abundant fruit season. Early protection of the buds is very important. Apricots and Peaches trained upon walls should receive first attention. Even where they are protected with glass or other coping, it may still be necessary to place blinds or heavy nets in front of the trees. These blinds or nets should be kept quite clear of the branches, by the aid of wires or other supports, placed about 3 or 4 feet apart, and reaching from the ground to the top of the wall. This safeguards the blossoms from injury by the movement of the protecting material during gusty weather. In less exposed or warmer localities, light netting or tiffany may afford adequate protection; but whatever may be the material used, it should be so arranged that the trees may be covered or uncovered quickly, and without risk of damaging the blossoms. Early covering is, in many instances, desirable, especially in places where late frosts are usual: the trees may thus be shaded during very bright weather, and this will help to retard the expansion of the flowers. On mild, dull days the protecting material may be removed, or partly so, but not during unsettled or stormy weather, cold winds doing as much or more damage to the blossom than actual frost. The sudden transition from cold to heat, which is often experienced during the sunny days and frosty nights of early spring, is the frequent cause of the failure of the fruit crops. The effect of shading or protection, however slight, during such weather, counteracts this evil more or less, and, by its use, frost is often prevented from fatally injuring the blossoms, which frequently recover from the ill-effects of an unusually sharp frost owing to the shading material screening them from the direct rays of the sun until a gradual thawing has taken place. It should be borne in mind that the object of covering is to protect, and not to accelerate the expansion of the blossom, and, as seasons and localities differ so much, the cultivator must be somewhat guided by these considerations. Bush fruit trees growing in open quarters of the garden may be protected from frosts and cold winds by placing branches of evergreens around them, if more suitable material is not procurable. This easily-applied and temporary protection will often aid in securing a crop of fruit, when unprotected trees fail.

FIGS.—Fig trees may now be planted, and many successful cultivators consider the present time the most favourable season. Trees which have been growing in pots should be disturbed at the roots as little as possible, unless the latter are in a very matted condition by having remained too long in the pots, in which case the roots must be carefully separated and spread out during the operation of planting. If planted against a wall, the soil about the roots should be well watered, and, after allowing a few days for the soil to settle, the shoots should be carefully tied in or nailed to the wall to prevent them from being broken. Cover the surface of the soil with littery material in order to keep the roots moist

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

PELARGONIUM.—Plants of Show and Regal Pelargoniums that are intended to flower from late May until well into July should be afforded a shift into larger pots, provided that the ball was reduced in the autumn when the plants were started afresh after pruning. Employ a mixture of good, loamy soil, decayed leaf-mould and silver sand. Pot firmly, and avoid over-potting, which would cause the plants to make too much growth at the expense of flowering. Allow the plants to have all the light possible, keep a close watch for aphid, and afford water with great care. The old Fancy Pelargoniums do best in smaller pots than are allowed for the more vigorous-growing types. The batch of plants of the Zonal-leaved section intended for flowering next winter should now be raised from cuttings. It is preferable to place one shoot in a thumb pot rather than several in a large receptacle.

FERNS.—It is desirable to effect a general overhauling of the entire stock of Ferns early in the present month. During the period of comparative inactivity which is now closing, there have been plenty of opportunities of ridding the plants of thrips, scale, or other troublesome insects that are liable to attack them. With the numerous insecticides and materials for fumigation now available, the cultivator need have but little difficulty in keeping his plants clean, but if any specimens are affected with pests at the present time, they should be cleansed thoroughly before any repotting is commenced. It is probable that more Ferns are now grown as decorative plants than has ever been the case, and the plants constitute an interesting feature in Fern cultivation. But the cultivator, whilst paying every attention to decorative Ferns, should not neglect other useful and ornamental species and varieties. The gold and silver Gymnogrammes are worthy of more attention than is now given them, and the same may be said of the wonderfully attractive Ferns, the Gleichenias. It is a fact that the species of Gleichenia are not of the easiest cultivation, but this circumstance should not deter but rather encourage gardeners to endeavour to understand their peculiarities and satisfy their requirements. It is never expedient to force Ferns in any way whatever.

DECORATIVE FERNS.—Most of the decorative Ferns are probably in small pots; therefore, if the plants are vigorous they may be shifted into pots one size larger. In the potting of decorative Ferns it is scarcely desirable to select any but vigorous, healthy specimens for further cultivation. The weakly or unhealthy ones should be cast away. It is easy to raise stocks of decorative Ferns to supply as many plants as are required. *Adiantum cuneatum* is still without a rival for supplying fronds for cutting. At the present time many chance seedlings of this species may be found in the various houses, and it is a good plan to look out for and cultivate them. The older plants may be divided for the purpose of increasing the stock, unless they are required to make larger specimens. *Adiantum cuneatum* and *A. tenerum* Farleyense require a good proportion of loam in the soil. If this is used the fronds may not develop so deep a green, but they will be more enduring. Firm potting is essential in all cases. The plants require all the light possible during the next few months, indeed, I do not shade this species except in the very hottest weather. In potting *Gymnogrammes* more peat is needed, but the potting should still be done very firmly. *Gleichenias* require peat broken up roughly except in the case of *G. flabellata*, which thrives better in fibrous loam. All the filmy Ferns succeed best in a rough soil consisting chiefly of peat, but containing a small proportion of light, turfy loam. They need such a great amount of moisture that it is important to exclude all the finer particles of soil.

NEPHROLEPIS.—The development that has taken place in *Nephrolepis exaltata* is perhaps the most interesting fact in modern Fern cultivation and the beauty and utility of the many varieties are beyond dispute. The best of these should be afforded plenty of room, and cultivated as decorative plants, whilst for cutting, the fronds will be found more enduring than those of most other Ferns. *Nephrolepis* may be easily increased at the present time by division, or by offsets.

BASKET FERNS.—Many kinds of Fern appear to the best advantage when cultivated in baskets. *Adiantum assimile* makes a good basket Fern, so does *Asplenium caudatum*, whilst many *Davallias* and varieties of *Nephrolepis* are equally valuable. It is better to remake up any baskets containing Ferns which show signs of exhaustion than to attempt to increase their vigour by the use of stimulants.

TREE FERNS.—Attend to any tree Ferns in tubs or large pots that need more root room or a top dressing. It may in some instances be impossible to extend the rooting medium without reducing the balls of soil and roots, and this latter operation is rather a risky experiment. If it has to be attempted, some *Sphagnum*-moss should be wrapped around the stem, and kept damp until the plant is again established. It should be packed firmly, but not too thickly around the stem, and bound tightly in position. Tree Ferns that have been planted out should be given a top-dressing. The plants will soon be developing their growth, and it is important not to allow them to suffer from want of water. *Dicksonia squarrosa*, for example, will show injury if allowed to suffer the slightest draught. If there is any sign of thrips upon the fronds, syringe the plants frequently.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

PLANTING OF VINES.—If the borders have been properly prepared, the planting of young vines may now be commenced in gardens where the canes are planted out while they are still dormant. In our own case, we prefer to plant just when the buds are beginning to move. Shake out the soil from and carefully disentangle the roots, removing with a sharp knife any that are damaged, and always cutting from the under to the upper side. Lay the roots out evenly and flat, a few inches below the surface of the border and cover them with some of the finest soil, making the whole firm. Apply sufficient water to settle the soil about the roots and mulch the surface with spent horse-droppings or similar material. Support the young canes loosely until the roots and soil have settled into position. Damp the surfaces in the house frequently and close the ventilators sufficiently early in the afternoon to cause the temperature to rise from sunheat. If the vines were pruned to the required length whilst they were dormant in the pots, any buds not needed should be rubbed out, and the portion of the old cane thus disbudded retained for a time, as it will act as a support to which the young growths may be tied, and may be removed at a later date, when there will be no fear of any bleeding.

GRAPE THINNING.—The thinning of Grapes will occupy a considerable time during the next few weeks, and it may be found difficult to keep up with the work so that all the bunches may be given attention at the time they need it. In the case of free-setting varieties an early start should be made upon these bunches which set earliest, remembering that there is nothing to be gained by allowing the berries to swell too much before they are thinned. A good pair of scissors is essential, and they should be kept very clean by rubbing them with sand-piper at the close of the day, afterwards suspending them in a dry position. In addition to the scissors the operator will require a smooth, thin piece of stick, with a small fork, for holding the bunch in position and otherwise moving the berries. The extent of the thinning will vary in the different varieties, but at the commencement the berries in the interior of the bunch may be removed and any small and seedless berries, cutting them out as cleanly and neatly as possible. Any shoulders to the bunch should be neatly but securely tied up with a twist of raffia, so that the berries are clear of each other, and the shoulders do not rest upon the uppermost berries of the bunch. A common mistake is made in thinning these uppermost berries too severely; consequently the top of the bunch is made to present a naked appearance. In carrying out the necessary thinning give care to preserve the general outlines of the bunch. Any subsequent thinning that is required should be done before the berries get too large, otherwise the danger of pricking them with the scissors can scarcely be avoided. Care should be exer-

cised at all times not to handle or rub the berries in any way.

STRAWBERRIES.—The earliest Strawberries should be removed to cooler houses as soon as the fruits commence to colour. In this stage they need a less humid atmosphere, and may be kept just a little drier at the roots. If these details are not observed the fruits will probably be very insipid. Later bunches now in flower should have the flowers thinned, but not so severely as the earliest plants.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

RHUBARB.—The plants in the open garden may be given some protection in order that they may afford supplies as early in the season as possible. If only a small quantity is desired, a few large pots may be placed over the crowns and sufficient fermenting material placed amongst them to produce the necessary heat. But where large quantities are necessary, hurdles may be placed over the rows in span-roof fashion and covered with fermenting material prepared for the purpose.

TURNIPS.—A small sowing of the variety Early Milan may be made either in an unheated pit or on a warm border, sowing in drills 9 inches apart and 1 inch deep. When the seedlings appear, frequent dustings of soot will be necessary to preserve them from birds and other pests. Small sowings of Turnips should be made weekly during March and April in order to avoid a break in the supply through any plants bolting into flower. Turnips must grow quickly if they are to be mild, and they should be sown on good rich land, made moderately light.

BRUSSELS SPROUTS. The main sowing of Brussel Sprouts should be made at once, selecting a border sheltered from rough winds for the seed bed. Sow the seeds in drills drawn at 1 foot apart, as this will permit of hoeing among the plants. Two suitable varieties are Ideal and Dwarf Gem. These furnish small, solid Sprouts, but if larger ones are required select Scrymgeour's Giant or Aigbarth. Brussels Sprouts are the most reliable of all winter vegetables, and should be extensively planted where green vegetables are much in demand. The young plants raised from seeds sown early in February are now of a suitable size for transplanting, but they must be afforded protection. If it is convenient, plant them in a portable frame which can be removed entirely later, and utilised for some other crop.

CAULIFLOWERS. Seeds of Cauliflowers may also be sown at this date to furnish plants to succeed the batch sown in boxes about six weeks ago. Magnum Bonum and Early London are reliable sorts for early summer supplies. Veitch's Autumn Giant and Hallow'e'en Giant may be sown a fortnight later, and these varieties will furnish heads late in the autumn. Hallow'e'en Giant may be cut in good condition as late as the end of November if the plants are protected from severe frosts.

CABBAGE.—Seeds should now be sown, so that there may be no scarcity of plants for summer supplies. All these small seeds of the Brassica tribe need to be protected from birds by stretching some fish netting over the seed beds. Where slugs are troublesome they may be kept in check by a dusting of hot lime applied in the early morning.

SEAKALE.—Roots of Seakale intended for forcing in pits or other glasshouses should be lifted, and placed in a cool shed or stored until they are required. The crowns should not be exposed to the light after they have commenced to grow, or the quality of the heads will be inferior. Roots intended for forcing in the open should be covered with ashes in order to exclude the light until they are covered with inverted pots. Seakale grown in this way is altogether superior and stouter than when lifted and forced in a high temperature, but it is only at the commencement of March that profitable turnips can be obtained from this method of forcing. If the crowns are growing in clumps at a suitable distance apart, all that is necessary is to place the pots over them, and to fill in the spaces between the pots with some fermenting materials.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Illustrations. The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens or of remarkable plants, flowers, trees, &c., but they cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 13—United Hort. Benefit and Prov. Soc. Ann. Meet. at R.H.S. Hall, 8 p.m.

TUESDAY, MARCH 14—Roy. Hort. Soc. Cons. meet and Spring Bulb Show (Sixth Masters' Memorial Lecture at 3 p.m. by Mr. G. F. Scott-Elliott, M.A., on "Origin of Varieties"). Horticultural Club Meeting.

WEDNESDAY, MARCH 15—R.H.S. Bulb Show (second day). Roy. Meteorological Soc. meet.

THURSDAY, MARCH 16—Linnæan Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich 41.6°.

ACTUAL TEMPERATURES:—LONDON.—Wednesday, March 8 (6 P.M.): Max. 47°; Min. 30°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 9 (10 A.M.): Bar. 29.9; Temp. 45°; Weather—Raining.

PROVINCES.—Wednesday, March 8 Max. 15 Ireland S.E.; Min. 4° Ireland N.E.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—Hardy Bulbs, Lilies, Herbaceous Plants, &c., at 12; Roses, Fruit Trees, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—Border Plants and Perennials, Hardy Bulbs and Roots, at 12; Roses, at 1.30; Trade Sale of 1 lumps, &c., at 2.30; Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris. Clearance Sale of Surplus Nursery Stock, at the Central Hardy Plant Nursery, Cuthbert, by order of Mr. F. Brazier, by Protheroe & Morris, at 12.

FRIDAY—Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12 P.

British Botanists: Sir William Hooker.

The fourth lecture in the course of advanced lectures on the History of British Botany was delivered recently at University College, by Professor Bower, the subject being "Sir William Hooker." Sir William Hooker, for 29 years Regius Professor of Botany in Glasgow and for 25 years Director of Kew, may be styled the great founder of scientific gardens of the Victorian period. During his Professorship in Glasgow, he raised the garden just established there to a state of scientific efficiency it has never known since. He was appointed to Kew in 1811. When he entered into the office of Director he found the garden hardly a scientific establishment at all. He left Kew, at his death in 1865, with all the essentials supplied for its growth into the great scientific establishment it now is. In addition to this, he left a record of personal observation, in his published works, which is probably unequalled in extent by the achievements of any other systematic botanist.

Hooker was born in Norwich in 1785, coming of an old Devonshire family, which had established itself in East Anglia. He inherited a competence at the early age of four, and thus was saved the period of struggle for a livelihood in early life. His surroundings were favourable to his natural tastes for science, and he became acquainted, while still very young, with the leaders of botanical enquiry, such as Dawson Turner, Sir James Smith, Robert Brown and Sir Joseph Banks. Little need be said of his early years till 1820, beyond that they were marked by exact study, and by the publication of his *British Jungermannia*, which is still a classic.

In 1820 he was appointed by the Crown to the Chair of Botany in Glasgow. His 20 years there resulted in the raising of the newly-founded Botanic Garden to a position such that "it would never suffer by comparison with any other similar establishment in Europe." His work in the University included the instruction of medical students and others, who spread as collectors to various quarters of the globe. His own publications issued in a stream as continuous as it was voluminous. The most notable works of this period were the second edition of Curtis's *Flora Londinensis*, the *Flora Boracii Americana*, the *Botanical Results of Beccley's Voyage*, the *Foundation of the Icones Plantarum*, and the *Genera Filicum*.

In 1811 came the appointment to Kew Gardens, which had just been transferred from their original condition as an appanage of Kew Palace, to the Commissioners of Woods and Forests. The garden was small; all the plant-houses were old; there was neither Herbarium nor Library; and the Chief Commissioner was unsympathetic. In the 25 years of his directorate Sir William Hooker saw the extent of the gardens greatly increased, new plant-houses erected—including the great Palm House, and the central block of the Winter Garden and the Museums, the Herbarium, and Library established. The Herbarium was indeed created out of the generous gift of his friend Bentham, together with his own unrivalled collections. These had throughout his official life been always accessible to students: they were finally purchased by the nation after his death, but for many years previously they had been placed in the building now known as the Herbarium in the garden. The establishment at Kew has grown greatly since Hooker's death in 1865; but as he left it the essentials were already present which should constitute a great Imperial garden. This was the object laid down by Dr. Lindley, the report of which was accepted as a guide by Sir W. Hooker when he entered office. The intention was to establish a co-ordinating centre for all the botanical enterprises of this country and her dependencies. This was in a measure realised by Sir Wm. Hooker himself, and has become more thoroughly established by his successors in office.

But notwithstanding the great demands upon his time and energies which the

foundation and extension of such an establishment necessarily made, Sir Wm. Hooker continued his own description and delineation of plants. In the figures, he was ably assisted by Walter Fitch, who was his botanical "limner" during all the later years. Sir Joseph Hooker has estimated that Sir William published during his life about 8,000 plates, of which about 1,800 were from drawings by his own hand. These illustrations ranged from flowering plants to Ferns and Hepaticæ, while his very first efforts were in illustration of the Fuci in Dawson Turner's work on those plants. But of all Hooker's works, probably the most permanent, as they were certainly the most coherent and exhaustive, were his contributions to the knowledge of Ferns. He may be held to have been by far the most distinguished pteridologist of his time.

He wrote three great works on the Ferns, each of them complete in itself. They were the *Genera Filicum*, in one royal octavo volume, with 126 coloured plates, published in parts (1830-1840). In it he accepted provisionally the limitations of Presl in his *Tentamen*. This was followed by the *Species Filicum*, which Sir Joseph mentions as probably the most enduring monument to his father's labour as a systematist and descriptive pteridologist. It appeared in five octavo volumes with 304 plates (1846-1864), and embraced 2,500 species. In it, however, many of the genera of Presl were merged in larger genera. The "lumping" of genera comes out more clearly in the *Synopsis Filicum*, which was left unfinished at his death, and was completed by Mr. J. G. Baker. This, which is the well-known book of reference for all who work with Ferns, is, in fact, a condensation of all his other work on the family. It deals with 75 genera and 2,252 species. Clearly there was a great reduction in genera upon the 135 of Presl. It may be said that the result of the later work has been to show that Sir William carried the fusion of genera too far, in the acknowledged interest of facility in diagnosis. Many of his merged genera are now being reconstituted. But this is only a question of method. The real value of these works which occupied him so worthily in his later years, and indeed almost to the day of his death, lies in the accuracy of observation, of delineation, and of verbal record. These are qualities which give his work a durability which time will not impair.

The life of Sir William Hooker was long and arduous. He worked early and late, and seldom took a holiday. His labours were continued to his 81st year. The output was immense, but its effect will be permanent and fundamental. It supplied the necessary basis for co-ordinating the scientific effort of the Empire. At the same time it supplied that foundation of trustworthily fact upon which the more modern phyletic structures can safely be built. He was essentially a botanist of the pre-Darwinian period. But the structural material which he supplied is durable in quality and lies ready to the hand of the evolutionist.

CHELSEA ROYAL HOSPITAL, IN WHOSE GROUNDS THE INTERNATIONAL HORTICULTURAL EXHIBITION WILL BE HELD IN 1912.

THE BOTTOM PICTURE SHOWS THE GARDEN PLOTS CULTIVATED BY THE SOLDIER PENSIONERS.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees of this Society will take place on the 14th inst. A feature of the show will be the displays of Spring Bulls. At 3 p.m. the Sixth Masters' Memorial lecture on "The Origin of Varieties," will be delivered by Mr. G. F. SCOTT ELLIOTT, M.A., B.Sc.

NATIONAL DAHLIA SOCIETY.—At the conference on Dahlias to be held under the auspices of the National Dahlia Society at Carr's Restaurant, Strand, on Friday, March 17, at 6 p.m., Mr. EDWARD MAWLEY, V.M.H., will occupy the chair. Mr. JOSEPH CHEAL will read a paper on "The Single Dahlia, its Cultivation and Use," and Mr. GEORGE GORDON, V.M.H., a paper on "Decorative Dahlias," with special reference to early and abundant production of flowers.

LINNEAN SOCIETY.—The next general meeting of the society will be held on Thursday, the 16th inst., at 8 p.m. Exhibitions:—1, Mr. R. S. ADAMSON.—An ecological study of a Cambridge-shire wood (with lantern slides); 2, Mrs. SCOTT, F.L.S.—*Traquairia*: an organism from the Carboniferous rocks (with lantern slides). Paper:—Miss S. M. BAKER.—On the Brown Sea-weeds of the Salt Marsh.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this society will be held in the Royal Horticultural Hall, Westminster, on Monday, March 13, at 8 p.m. The chair will be taken by Mr. CHARLES H. CURTIS.

ROYAL METEOROLOGICAL SOCIETY.—A meeting of this society will be held at the Institution of Civil Engineers, Great George Street, Westminster, S.W., on Wednesday, March 15, when Professor H. H. TURNER, D.Sc., D.C.L., F.R.S., will deliver a lecture, illustrated by lantern slides, on "What can we learn from Rainfall Records?"

ROYAL WARRANTS TO NURSERY AND SEED FIRMS.—The Royal Warrant of Appointment to the KING has been conferred on Messrs. WM. PAUL & SON, LTD., Waltham Cross, as Rose Growers to His Majesty. The same firm have also received a Warrant of Appointment as Rose Growers and Nurserymen to Her Majesty QUEEN ALEXANDRA. Messrs. DICKSON, BROWN & FAIT, Corporation Street, Manchester, have received the Royal Warrant of Appointment as seedsman to QUEEN ALEXANDRA.

WORSHIPFUL COMPANY OF GARDENERS.—QUEEN MARY has accepted an offer made by this old City guild to provide Her Majesty with a banquet on the occasion of her coronation. The QUEEN's brother, the DUKE OF TECK, has recently become a member of the company.

CHRYSANTHEMUM MADAME R. OBERTHUR.—This fine white Chrysanthemum is one of the best varieties for late blooming, the flowers being very suitable for decorative purposes. Some excellent blooms have been sent us, since the commencement of the present month, by Mr. G. F. HYLAND, Ashby St. Ledgers Gardens, Rugby. They are of medium size for a Japanese variety, with curling and reflexed florets, some of them showing a trace of rose colour.

THE HEPATICÆ OF SCOTLAND.—Students of the Liverworts will welcome Mr. SYMERS M. MACVICAR's work published in the *Transactions and Proceedings of the Botanical Society of Edinburgh*, xxv., on the "Distribution of Hepaticæ in Scotland." The records of localities for the several species are preceded by an interesting account of the Liverwort flora of the region and a comparison of Scotland with other countries with respect to this group of Cryptogamous plants.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The King has forwarded his annual subscription of £5 to the Gardeners' Royal Benevolent Institution, of which His Majesty was formerly President.

"THE BOTANICAL MAGAZINE."—The issue for March contains descriptions and illustrations of the following plants:—

RHODODENDRON SUTCHUENENSE, tab. 8362.—This species of *Rhododendron* is one of Mr. E. H. WILSON's earliest introductions from China, whilst plant collecting for Messrs. JAMES VEITCH & SONS. The plant bears a fine truss of rose-coloured flowers, and blooms whilst very small. Although perfectly hardy, it is advisable to select for it a position shaded from the morning sun, as the blossoms expand in March, and are liable to damage when frosted if caught by the early sun. *Rhododendron sutchuense* is common on the higher mountain slopes of Western Hupeh, and it also grows in the district of Szechuan.

PRIMULA MAXIMOWICZII, tab. 8363.—This purple-flowered species of *Primula* is described and figured in *Gardeners' Chronicle*, April 2, 1910, p. 221, fig. 96, from specimens exhibited by Messrs. JAMES VEITCH & SONS, who received it from their collector, Mr. W. PIERCE. It is a native of the mountains of Northern Wei ching, and has been recorded from Shansi.

MECONOPSIS SIMPLICIFOLIA, tab. 8364.—This species of *Meconopsis* is not new to gardens, but it is one of the most distinct, having clear, blue flowers. The plant was first met with by WATSON in Nepal in 1819, and was introduced to horticulture by Sir JOSEPH HOOKER, from Sikkim, in 1848. *M. simplicifolia* is rather difficult to cultivate, especially in the seedling stage, but it thrives fairly satisfactorily in the Royal Botanic Gardens at Edinburgh, and much better than it does in districts further south: the plants usually flower in their second season.

CLEMATIS MONTANA VAR. WILSONII, tab. 8365.—*Clematis montana* is a very variable species, and no fewer than 10 distinct varieties have been found in Sikkim, Tibet, and Yunnan. Plants of the variety under notice flowered in the Cobble Wood nurseries of Messrs. JAMES VEITCH & SONS in July, 1909. *Clematis montana* does best in a rich, loamy soil containing calcareous matter; at Kew, where lime is absent from the soil, slaked lime is added when planting this and other *Clematises*, with beneficial effects.

CIRRHOPETALUM LONGISSIMUM, tab. 8366.—This species of *Cirrhopetalum* was shown by Sir TREVOR LAWRENCE, Bart., at the meeting of the Royal Horticultural Society on November 23, 1909, and received a First-class Certificate from the Orchid Committee. A description of the plant was given in our report of the show (see *Gardeners' Chronicle*, November 27, 1909, p. 364).

AGRICULTURAL EDUCATION.—It is the common plaint that our rural industries are decadent, and that succeeding Governments offer no encouragement to remedy the existing state of affairs. Small holdings are on trial, but it is felt in some quarters that further facilities are needed in this direction before they can become a success, and also that children in rural districts need educating in those subjects which they will naturally follow in after life. It is interesting therefore to learn that a Bill has been introduced in the House of Commons by Mr. JESSE COLLINGS to afford further facilities for the creation of Small Holdings, and side by side is a movement, initiated by Mr. COLLINGS, for promoting agricultural education and nature-study in public elementary schools, to enable local education authorities to provide and maintain means and facilities for the purpose of giving instruction in any of the following subjects:—nature-study; fruit, flower,

and vegetable growing; poultry and bee keeping; budding, pruning, and grafting; cow and pig keeping; milking; rotation of garden crops; nature and properties of soils; use of manures; knowledge and choice of seeds; structure, life, and food of plants; action of birds and insects on crops; choice and use of simple tools; packing fruit, vegetables, and other produce for market.

THE AGRICULTURAL NOTE BOOK.—This attractive little pocket-book, which is a companion volume to *The Horticulturists' Note Book*, is a compendium of farm data, compiled by Mr. PRIMROSE McCONNELL, B.Sc. It deals with almost everything concerning the farm in statistical or tabular form, and there are useful notes on forestry for the farmer, as well as a few details on market gardening. If information is required on the cost of any farm operation, the value of a certain manure, the returns to be expected from different crops, the weight of a plough harness, or how to make axle grease, the pages supply the knowledge. Similarly may be found tables and data concerning the dairy, live stock, including poultry; machinery, buildings, levelling, and all ground operations. The student will find the book invaluable, and save him much research amongst text books and papers.

PRIMULA SINENSIS VARIETIES.—Mr. BUDDÉ, Curator of the Botanic Gardens, Utrecht, Holland, writes to say that he wishes to obtain for scientific purposes a dozen plants of *Primula sinensis* var. *Primrose Queen* and *P. s.* var. *Crimson King*. Mr. BUDDÉ would like to obtain long and short styled flowers.

NICOTINE AS AN INSECTICIDE.—A report from Mr. G. H. GARRAD, Botanist at the South-Eastern Agricultural College, Wye, Kent, on the growing of tobacco in Kent last season, calls attention to the urgent need of allowing fruit growers to grow tobacco for use as an insecticide. It was proved many years ago that excellent crops of tobacco, so far as bulk is concerned, could be grown in England, and the proof was repeated in Kent last year. As Mr. GARRAD points out, the crop could be easily rendered unfit for smoking by being sprayed with some offensive-smelling wash just before cutting it. There would be no need of any expense in picking the leaves or any elaborate process of extracting the nicotine, as the plants could be boiled, stems and stalks included, to obtain an extract for spraying. This would be cheap enough for extensive use by fruit and hop growers, whereas at present nicotine is so costly that its use is next to impossible. Irish farmers are allowed to grow tobacco under proper supervision; then why not British fruit and hop growers? The experiments in Kent were allowed by express authority. As they have proved successful, the Government might well be urged to pass a Bill authorising growers of fruit or hops to grow tobacco for their own use as an insecticide.

THE POULTRY INDUSTRY.—The *Journal* of the National Poultry Organisation Society (January, 1911) contains an interesting report by the hon. secretary, Mr. EDWARD BROWN on the poultry industry in Germany. The salient features of the report are, that Germany is now the world's greatest importer of eggs, that by reason of the proximity of Germany to various European centres of production, Russia, Italy, and Austria-Hungary, the supplies of eggs from these countries are likely to be diverted more and more from this country to Germany, that the price of eggs in Great Britain is likely to increase owing to the shortage in supplies, and "a 6d. new-laid egg is a probable proposition" in the near future; therefore, no effort should be spared to extend the poultry industry in Great Britain and Ireland.

THE STINGING TREE OF FORMOSA.—In the course of an interesting communication to *Nature* (March 2, 1911), Mr. TOKUTARO ITO suggests that an appropriate name for the Formosan Stinging Tree (*Laportea pterostigma*) would be *Mamushi-no-ki* or *Viper Tree*. Contact of the leaves of this tree with the skin produces maddening pain, which lasts a day and a night, and hence it well deserves the old Chinese name which signifies Man-biting-dog. *Laportea pterostigma* attains to a height of about 10 feet, has long and large leaves resembling those of the Tobacco plant, and provided—needless to say—with stinging hairs. Other species of the genus *Laportea* which belongs, like the Stinging Nettle *Urtica dioica*, to the *Urticaceae* also possess this remarkable property. Thus, as described in our pages (1882, xviii., p. 465), *Laportea crenulata*, the Stinging Tree of Queensland, produces even more agonising effects than those ascribed to *L. pterostigma*:—"Its effects are curious. It leaves no mark, but the pain is maddening, and for months afterwards the part, when touched, is tender in rainy weather, or when it gets wet in washing, etc. I have seen a man who treats ordinary pain lightly rolling on the ground in agony after being stung, and I have known a horse so completely mad after getting into a grove of the trees that he rushed open-mouthed at everyone who approached him, and had to be shot. Dogs when stung will rush about whining piteously, biting pieces from the affected parts." Mr. N. E. BROWN has also described, in the same number of the *Gardeners' Chronicle* that contains the above account, his personal experience of the virulence of the sting caused by plants of *Laportea crenulata* grown in the Palm House at Kew.

SPRING-FLOWERING TREES AND SHRUBS.—In the course of an interesting article on the cultivation of spring-flowering woody plants, Mr. B. VOIGTLÄNDER (*Die Gartenwelt*, xv., 8) draws attention to a number of shrubs and trees which have claims on the consideration of those who are able to practise this most charming branch of landscape gardening. Among the spring-flowering woody plants mentioned by Mr. VOIGTLÄNDER are the following:—*Corylopsis pauciflora* opens its yellow-white flowers before the leaves appear, bearing them in slender, somewhat depending branches. *Corylopsis spicata* bears larger flowers but is less free of flowering, and only comes into full flower-bearing state when it has reached a fair age. For propagation of these species, layering is recommended, or cuttings may be taken of the leafy shoots—with a heel of old wood—in May-July. They root in moderate warmth in a propagating house in from four to seven weeks; but great care must be taken to prevent the cuttings from withering. Potted up, the rooted cuttings may be placed in a cold frame, but should be protected during the winter from hard frost and planted out the ensuing spring in well drained soil. *Amygdalus persicoides* is a small tree bearing its blossom in early spring. The flowers are white, with a slight rosy flush and upwards of an inch in diameter. The decorative effect of the flowers is enhanced by a large carmine-red spot on each petal. Though, like most species of *Prunus*, the flowers do not last long, they have the merit that they are not destroyed by a light spring frost. Among the Peaches, mention is made of the red-leaved variety, *Amygdalus persica atropurpurea*, which bears dark rose coloured flowers. Of Ribes, *R. niveum*, *R. multiflorum* and *R. petraeum* are recommended. They bear respectively white, green-yellow, and bright brown flowers; in the two latter species the flowers arise in clusters, in *R. niveum* singly. In peaty soil, *Leucothoe nummularia* and *L. recurva* thrive well. The former species remains small, and is

covered in spring with small, starry flowers, the latter reaches 6 feet in height and bears upright racemes of white flowers. In addition to various species of *Prunus*, *P. baldschuanica*, *P. triloba*, &c., and species of *Berberis* as *B. Thunbergii* and the hybrid *B. stenophylla* (*Darwinii* × *empetrifolia*), Mr. VOIGTLÄNDER refers to *Diervilla hortensis præcox* (Lemoine), which is one of the first of early-flowering shrubs to produce its masses of deep rose-coloured flowers.

HORTICULTURAL CLUB.—The next house dinner of the club will take place on Tuesday, the 14th inst., at the Hotel Windsor. The members on this occasion will dine with the provincial secretaries of the Royal International Horticultural Exhibition. After the dinner, Mr. A. D. COTTON, F.L.S., will deliver a lecture on "Fungi." The lecture will be illustrated with lantern slides.

SOIL NITRATES.—The quantity of nitrate in a soil has long been regarded as affording an important criterion of its fertility, and it is equally well known that the amount is largely dependent on the kind of crop grown. Some recent experiments made by Drs. LYON and BIZZELL, of Cornell University, have added considerably to the knowledge of this question. On the same soil the amounts of nitrate under such crops as Timothy, Corn, Potatoes, Oats, Millet, were different for each crop and different from those in the soil lying fallow. It is of interest that during the most active growing periods there was more nitrate present in the soil under Corn than in the same cultivated soil bearing no crop, and it would appear that nitrification is directly stimulated by some of the processes connected with the active growth of plants, particularly Corn. On the other hand, during the later stages of growth, the nitrates in the cropped soil were actually disappearing, while those in the uncropped soil were increasing, pointing to the possibility of plants exerting a retarding influence on nitrification during their later period of growth. Inherent differences between different plants in their stimulating or inhibiting effect may afford an explanation of the large differences in the amount of nitrates under the various crops. The experiments serve to illustrate the important influence exercised on the soil by the plant grown in it, a factor which is too apt to be overlooked.

BOTRYTIS CINEREA ON GREENHOUSE PLANTS.—*Botrytis cinerea* frequently causes serious damage to various kinds of greenhouse plants. It usually begins its existence as a saprophyte upon leaves and other plant organs which have died from various causes, but after living for a time upon dead materials the mycelium, or spawn of the fungus, frequently attacks healthy tissues. If the conditions of temperature and dampness are favourable, the mycelium grows vigorously, and quickly kills the plants which it attacks. Once in this destructive phase, the fungus is very difficult to control. When the temperature is high and the atmosphere is saturated with moisture, the fungus may remain in a sterile state, not forming spores; under these conditions the mycelium may form a kind of network over the soil, and is then known to French horticulturists as "la toile." In other conditions, however, *Botrytis cinerea* produces innumerable spore-bearing branches, each of which, when seen under a lens or microscope, looks like a miniature bunch of Grapes. It is important to remember that when ventilation is good, and the plants are not watered excessively, there is little danger of an epidemic of this fungus. Should the pest, however, develop in virulent form, the soil becomes badly infected, and, under these circumstances, it is advisable either to sterilise the soil or to use fresh soil for the plants subsequently grown.

CHELSEA HOSPITAL.

(See Supplementary Illustration.)

CHELSEA HOSPITAL is of more than usual interest just now to gardeners, on account of the great International Horticultural Exhibition which will be held in its grounds in May next year. The hospital was founded during the reign of Charles II. to provide a home for old and disabled soldiers, the architect being Sir Christopher Wren. The foundation stone was laid by Charles in 1681-2, but the building was not completed until 1694. The lands of the hospital, including portions covered by buildings, comprise about 66 acres, situated between the River Thames and King Street, Chelsea, a street that has considerable horticultural interest in being the home of several famous nurseries, some of which have disappeared to meet the demand for building land. The grounds of Chelsea Hospital are in no fewer than three parishes, the major portion, including almost all the buildings, being in the parish of St. Luke's, Chelsea. When the hospital was built the district was open country, and about 27 acres was originally included in the grounds; as time went on other land was added, and at one time the place was much larger than now; but in 1698, 27 acres were granted by the King to the Earl of Ranelagh, although a portion of this land was repurchased from the trustees of Lord Ranelagh in 1742, and another portion in 1826. These parts formed the famous Ranelagh Gardens, which were long used as a place of public entertainment.

The main building, a portion of which may be seen in the upper picture of our Supplementary Illustration, is built in the form of quadrangles with three central courts. In the centre of the middle one is a statue of the founder, Charles II. The south front faces a series of terraces, three in number, the lowest being relieved with large flower-beds that may be seen in the picture; the largest of these beds measures about 30 feet by 8 feet; the oval ones are about 16 feet across. The photographs from which our illustrations were prepared were taken during the summer when the beds were filled with summer bedding plants. In the centres of the larger ones are permanent plants of *Rhododendrons*. These only occupy a portion of the beds, the remaining parts being ample for the scheme of flower bedding. The oval bed seen immediately in the foreground was last summer planted in the centre with *Golden Gem Calceolaria*, outside of which was a row of the scarlet *Pelargonium Vesuvius*, and an edging of *Viola Bluebell*. The next bed was of white *Marguerites* that showed up well against the greenery of the *Rhododendrons*, with *Calceolaria Golden Gem* and a border of *Lobelia compacta*. Another large bed was filled with yellow *Antirrhinum* with a border of *Pelargoniums*, and edged with *Lobelia*. The tower seen immediately above the flower beds is the clock turret of Chelsea Barracks, and the trees are in the part known as Ranelagh Gardens. Between the terrace gardens and the River Thames is an open space of from four to five acres, known as The Flats, to which the public has access as well as to the Ranelagh Gardens. In the centre of The Flats is a large statue erected to the memory of 255 officers, non-commissioned officers, and privates of the 24th Regiment who fell at Chillianwallah on January 13, 1849. The grounds are partially excluded from the roadway on the river side by a mound which is planted with shrubs, but it is very difficult to cultivate other than the very commonest kinds owing to the smoke laden and foggy atmosphere. At one time, when there were fewer chimneys around, avenues of trees formed noble vistas leading to various parts. One, known as the Royal Avenue, was intended to reach to Kensington Palace, but it was not carried beyond the King's Road, which was originally a private

royal way from the London palaces to Hampton Court. One of the avenues is of more than usual interest, and consists of pollarded Limes. These trees were transplanted about 40 years since, and, the success of their removal being a matter of doubt, a row of young Planes was placed on either side in case they failed. Both, however, lived, with the result that in time the Plane trees overshadowed and crippled the growth of the Limes, while the latter spoiled the shape of the Planes.

The Ranelagh Gardens provide a great surprise in charming landscape effect. The ground is undulating in parts with broad lawns that are broken up by the skilfully planted clumps of trees and shrubs, whilst the boundaries are screened with trees and shrubs. A few flower-beds add a touch of colour in summer time. The Ranelagh Gardens are situated on the extreme south-west of the hospital grounds, and are contiguous with the pensioners' garden plots shown in the lower picture. These tiny gardens number 140, and each consists of about one rod of land. Each is a veritable garden in miniature, and the number of subjects that are crowded in a small plot tells of the great enthusiasm of the cultivators. Sometimes the plots are laid out with paths and tiny summer houses, or, as showing the proclivities of the owner, it contains a fort, built of pebbles gathered from the adjoining river's bank. Amongst the most successful plants that grow in these little gardens are Carnations, which do remarkably well; Dahlias, the tubers being buried in the soil in winter to protect them from frost; Sunflowers of the multiflorous type, and specially the old double alba plena variety, *Artemisia abrotanum* (Old Man), *Gladiolus*, and annuals, such as *Godetias*, Cornflowers, *Mignonette*, and Sweet Peas. Some of the cultivators favour vegetables, and crop their plots with such things as Radishes, Lettuces, Potatoes, Cabbages, including hardy Kales, Parsley, Beet, and similar kinds. Roses are sometimes attempted, but they are always a failure. The owners are expected to keep their plots in order, but there is seldom ground for complaint in this respect as the old soldier is usually a keen gardener. Sometimes the cultivator makes a visit on foot to Covent Garden to secure something fresh for growing, but, as a rule, an interchange of subjects provides the necessary stocks.

A competitive show is held each season, and 1st, 2nd, and 3rd prizes are awarded in three classes for (a) the best flower garden, (b) the best vegetable garden, and (c) the best mixed garden. On the north-east side of the pensioners' gardens is the old burying ground of Chelsea Hospital, with numerous tombstones each marking the last resting place of some old hero, one of the most interesting being inscribed to the memory of Wm. Hiseland, who married when he was more than 100, and died at the age of 112.

Near this part is situated the framing ground, in which are several glass-houses and frames that are filled with a variety of bedding plants. The garden superintendent is Mr. T. W. Turner, who will be well known to frequenters of the old R.H.S. Gardens at Chiswick, where he was foreman for many years.

A FLORAL ARCHWAY.

THE floral arch shown in fig. 69 was erected by the South African Railways Company at Johannesburg Railway Station, on the occasion of the recent visit of H.R.H. the Duke of Connaught.

The decoration was designed by Mr. Robert Phillips, Superintendent of Parks, Johannesburg. The groundwork was composed of clipped sprays of *Cupressus macrocarpa*, the pillars and panels of a white *Helichrysum*, and colour was supplied by other species of *Helichrysum*, and flowers of *Gnaphalium*, *Erica*, and other species.

Twenty men were engaged for two days and two nights in forming the arch.

NURSERY NOTES.

PRIMULAS AT FOREST HILL.

THE display of Primulas in Messrs. James Carter & Co.'s branch nursery at Forest Hill, is as fine this season as ever. The mild, dry weather, with few fogs this winter, has favoured the plants, and they have flowered exceptionally well. Most important of all, the seed-pods are swelling freely, giving promise for a good seed harvest, as this is the reason why nearly all the glass-houses are filled with the plants. Every care is taken to ensure the seeds setting, the flowers being dusted with a small brush during the brightest part of the day. It may easily be seen which of the blossoms need pollinating, for those that have been dusted with the brush soon lose their bright colours, the difference between the young and old blooms being very marked in this respect. Plants of a

another of the red shades, and there is also one named *Carmine Empress*, with double flowers, having the deepest shade of all the double Primulas in the collection. *Princess of Wales* is another pleasing double variety, having white flowers delicately tinted with salmon. *Holborn Crested* is of a light carmine colour, fading to white, and with a beautiful yellow "eye." *Double Scarlet* is excellent for furnishing cut blooms as the inflorescences are very freely produced and the colour is the nearest approach to scarlet in any of these Primulas. *Snowflake* is really a pale blush; it is a very early bloomer, and more valuable on that account. *Holborn Rose*, *Holborn Pink*, and *Holborn Queen* (white) are three good Primulas in their respective colours. There is also a variety of rose-shade known as *Rose Queen*. This is a very pretty sort, and the plant sends up a big inflorescence bearing large flowers. Amongst the seedlings of the year is one of great promise, which has been named *Raynes Park White*. It is

FIG. 69.—FLORAL ARCH ERECTED AT JOHANNESBURG, ON THE OCCASION OF THE VISIT OF H.R.H. THE DUKE OF CONNAUGHT.

moderate size give a better crop of seeds than vigorous ones, and the specimens are, for this reason, potted in small pots. Some of the varieties are much better seeders than others, and it is interesting to find that the fertile, double-flowered varieties are as prolific as any. The varieties grown by Messrs. Carter embrace all the beautiful colours seen in this flower, and there are examples with all the different types of foliage, including one with leaves like the Oak-leaved *Pelargonium*. The beautiful *Princess May* variety appeared as glorious as ever. It is one of the best types of a giant Primula, the blush-pink flowers being from 2½ inches in diameter. The plants are good growers, and have an excellent habit. *Holborn Coral* is one of a series of colours with the prefix *Holborn*, and it is one of the best of the set. The colour is especially clear and bright, and of a very attractive shade. The petals are large and of great substance, the variety being one of the best sent out by this firm. *Vermilion* is of the rich colour indicated by the name, whilst *Carmine* is

of the giant type, with stout, clear-cut petals, set off by a yellow eye; it has Palm-leaf foliage. The plant produces secondary trusses of bloom, so that the flowering is free.

An old favourite was seen in *Elaine*, which, to our liking, is one of the best of the white varieties in the nursery. There were large batches, too, which indicated its popularity in gardens. The blooms are certainly small, but this is compensated in their extra refinement and the plants' prolific blooming. The foliage, curiously enough, is dark in colour, and belongs to the palm-leaf type. *Giant Crimson* represents a large-flowered variety of this shade; the crimsons and other dark varieties are never so large in the flower as the paler ones, the most delicate colours, such as blush, salmon, and white, giving the biggest blooms. Thus, in *King Edward*, a white sort, the flowers are very large, and this Messrs. Carter regard as one of the finest varieties sent out by them. The inflorescences are developed well above the foliage, and bear a great number of

flowers. The petals have prettily-filled margins. In the variety Light Blue is seen the forerunner of this shade, and, although there are now others of deeper tone, it is still one of the clearest shades: lavender is perhaps nearer the tone than blue. The Bouquet type is remarkable for the leafy involucre, hence the name. Bouquet White was finely in flower, and stands up well above the circle of foliage borne on the flower-stalk.

In Giant Magenta the blooms are very true to colour, but the effect of pollinating them is at once seen, they become dull and the succeeding flowers much smaller. Orange King is of a most beautiful shade in the younger flowers, and efforts are being made to obtain the same tone in hybrids with large flowers. In other directions, too, crosses were being effected, as there are almost endless possibilities in the species, that has already provided greater variability, probably, than any other florists' flower. The stellata type, for instance, has furnished varieties with white, pink, blue, crimson, lilac, salmon, and other pleasing colours. These Star Primulas are as charming as any, and, with their lax inflorescences, are admirably suited for greenhouse and conservatory decoration.

Amongst other subjects observed at this Forest Hill nursery was a fine batch of Cinerarias, also a large house filled with Gloxinias, both these plants being in the finest condition, and promising a grand display of flowers in their season.

VEGETABLES.

BRUSSELS SPROUTS.

My method of cultivating Brussels Sprouts is as follows:—The seeds are sown in boxes about the end of February, and they are placed in ainery that has been started recently, or a glass-house with similar conditions. Germination takes place quickly, and shortly afterwards the boxes are transferred to a cold frame from which frost can be excluded. When the rough leaf has formed, the plants are pricked out into a cold frame at a distance of about 3 inches apart. They are sprinkled overhead with tepid water and kept close for a few days, after which time fresh air is admitted on all favourable occasions. The seedlings need to be shaded for a few days from bright sunshine, and the lights must also be covered when frost prevails. Throughout the latter part of April the lights are removed entirely, being replaced only if cold or frosty weather is evident, the object being to induce the plants to grow strong and sturdy by the time the weather permits them to be planted out. This is generally about the middle of May, the ground having been previously well prepared by manuring and deep working. The plants receive a thorough watering the day previous to planting, which is carried out carefully by means of a trowel. They are allowed a distance of 3 feet apart each way, and well watered after planting. If the ground is kept stirred occasionally with a hoe, the plants will grow quickly. When they are about 1 foot high, little mounds of soil are drawn up around the stems, to keep the plants steady in windy weather. The variety grown here is "Sutton's Exhibition," and treated as I have described, the plants never fail to produce an abundance of good solid Sprouts, furnishing a supply of buttons from October to the end of March. As the stem leaves turn yellow, they should be removed, for when these are left on the plants the flavour of the Sprouts is impaired. In addition to "Exhibition," we grow a few plants of the variety "Dwarf Gem." These are raised in the open ground, and furnish Sprouts after the main crop is over. *Wilmot H. Yates, Rotherfield Park Gardens, Hants.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

CORONILLA GLAUCA AND VERONICAS IN IRELAND.—Two plants of *Coronilla glauca* growing at the foot of a south wall here have been flowering since the middle of October. They are about 3 feet in height by 4 feet in diameter. Two other plants of the same species, which are not so favourably situated, have produced no flowers. The heavy rains during the month of December caused the flowers to damp, but, with this exception, the bushes have been a mass of bloom, and, at the time of writing (February 22), are conspicuous subjects. *Veronica Andersonii* flowered freely during November and December. Another dwarf *Veronica*, the name of which I am uncertain, has been flowering during the whole winter. The *Veronicas* are growing on a north border, and *V. Andersonii* has been injured somewhat by strong winds. A hedge of *Fuchsia Riccartonii*, 190 feet long, 8 feet high, and 3 feet in width, forms an attractive feature when in flower. Very slight frosts have been experienced this winter, and no snow has fallen. From the middle

MR. GEORGE MAYES.

to the end of January the weather was fine, clear, and calm. The first week in February was very bright. Lately, considerable rain has fallen, and strong gales have been experienced. *C. Ruse, Lambay Island, Rush, Co. Dublin.*

A NURSERY EMPLOYÉ'S JUBILEE.—A benevolent Government may some day institute a long-service medal for persons in civil life, and I have much pleasure in sending you a photograph of a veteran in the nursery trade who is deserving of the honour. Mr. George Mayes will be remembered by many of your Colonial readers who have worked in the Clapton Nurseries, for he has served in the Low family for half a century. Mr. Mayes still prefers to work, and, although he is turned 80 years of age, is as hearty as possible. *Lawrence P. Cook.*

FORCED SHRUBS.—The great variety of shrubs that may be forced into blossom at this time of the year has been well shown by Messrs. R. & G. Cuthbert at recent meetings of the Royal Horticultural Society. An outstanding feature of the displays was furnished by large bushes of *Magnolias*, of which *M. speciosa* may be especially mentioned. This, which is one of the garden forms obtained by crossing *Magnolia Yulan* or *conspicua* with *M. obovata*, is of freely-branched upright habit, and the leafless branches

are plentifully furnished with erect blossoms, white, or nearly so, inside, and with a purplish tinge on the exterior. Another *Magnolia* somewhat in the way of *M. speciosa*, but not so free in flowering, is *M. alba superba*. There have been also plants of *M. Yulan*, with pure-white blossoms, and *M. Lennei*. In order to break up the undulating surface of the group, numerous standard plants have been employed. Chief among these were the deciduous forms of *Rhododendron* popularly known as Azaleas; *Wistaria sinensis*, beautiful in its profusion of pendulous racemes of lilac-coloured blossoms; *Staphylea colchica*; *Prunus triloba*; *Laburnum*, most effective as a standard; Lilacs, and *Forsythia suspensa*. Dwarfier subjects of a more bushy habit included Lilacs, the pure-white *Marie Legraye* being very noticeable; *Rhododendron sinense* (*Azalea mollis* of gardens) in many forms, the rich, golden-yellow of *Anthony Koster* being in its colour still unsurpassed; *Staphylea colchica*, laden with blossoms; and the small, white-flowered *Spiraea Thunbergii*. This by no means exhausts the list of hardy shrubs available for forcing. The members of the *Prunus* family, which include the Almonds, Cherries, and Peaches, as well as Plums, are all available for forcing. Of the forms of *Prunus* proper, the pink and white varieties with double flowers, of *Prunus japonica*, known also as *Prunus sinensis*, are very beautiful as small bushes, and the blossoms remain fresh for a considerable time. *Prunus triloba*, alluded to above, is also a choice subject. The double-flowered Cherries are equally desirable, especially the form of *Prunus Pseudo-cerasus*, known as *J. H. Veitch*. This has very large flowers of a pink tint, while the tender, unfolding leaves are of a pretty, bronzy hue. Other subjects include *Amelanchier Botryapium*, the white flowers being borne in great profusion; *Andromeda floribunda* and *A. japonica*, pretty evergreens with white, wax-like flowers; *Choisya ternata*, with fragrant, white blossoms; *Cydonia japonica* and *C. Maulei*, of different colours; *Tree Peonies*; *Rhododendron Cunningham's White*, which seems identical with *R. caucasicum album*; *Cytisus Andreanus*, the flowers, when developed under glass, are richly coloured; *C. praecox*, with pale-sulphur blossoms; *Deutzia gracilis*, and some of the newer hybrid *Deutzias*; *Kalmia latifolia*; the *Laurestinus*, which blooms naturally during the winter months; *Ribes sanguineum*; *Spiraea confusa* or *media*, *S. prunifolia flore plena*, both with white blossoms; *Thorns* of sorts, which must not, however, be forced hard; *Viburnums*, particularly the Snowball Tree (*V. Opulus sterile*), and its Japanese representative known generally under the name of *V. plicatum*; *Weigelas* or *Diervillas* of sorts, especially the dark claret-red *Eva Rathke* variety, and the singular *Xanthoceras sorbifolia*. The Japanese Maples furnish beautiful foliage plants for mingling with these flowering shrubs. *H.*

SPREAD OF AMERICAN GOOSEBERRY-MILDEW (see p. 13).—So far as I am aware, no spread of this disease takes place in winter. The latest date on which the summer (or spreading) stage has been seen in this country was on November 8, at Wisbech. Curiously enough, this occurred in the same locality, and on the same date, in the years 1909 and 1910, but it is as well to remark that the quantity of summer stage then seen was very small indeed. However, a careful investigation of the case mentioned on p. 13, has been made, and the particular bushes mentioned have been closely examined. A few traces were found of twigs slightly affected with the usual winter stage of the disease, but beyond that there seemed to be nothing out of the common, or suggestive of any spread of mildew in winter. During a personal interview with the writer of the paragraph, I gathered from him that he had seen no white or true summer form of the disease during December, but the twigs to which he referred were simply brown at the tips, and of this discoloration there was very little indeed. There seems to be every indication that, as so often happens, some of the brown twigs were missed during the first two prunings mentioned. No doubt this would be on account of the dazing effect upon the eyes caused by constantly looking at the bushes. A fresh commencement of work after an interval would reveal the missed twigs to the workmen's eyes, which would naturally be keener after a period of rest. *M. M.*

SPECIMEN PLANTS AT EXHIBITIONS.—I was pleased to read the note by B. (see p. 123) on the specimen plant of *Cattleya Triana* exhibited by Sir George Holford at the Royal Horticultural Hall on the 14th ult. I agree with the writer that Orchids should be exhibited as fine specimens rather than as small plants in mixed collections. This *Cattleya* was more attractive than any group of mixed Orchids in the Hall. It is to be hoped that every effort will be made to present large, well-grown specimens of every description of plants at the Royal International Horticultural Exhibition in 1912. Not many of the present generation remember the wonderful specimens of Roses, Azaleas, Pelargoniums, and other genera which were such grand objects at the International Show of 1866. D.

LATE-KEEPING APPLES (see pp. 123, 139).—There is not the least doubt about English Apples paying for storing until February, provided that storage is done on a proper system. On p. 123, Mr. Molyneux quotes 6s. per bushel of 48 lbs. as the best price for Bramley's Seedling at Southampton in October last; at that time, the price in this district would be about the same, but now the same quantity is worth 8s. 9d. wholesale, which is an increase of nearly 50 per cent. It would be interesting to know if a similar increase in price occurred at Southampton. In regard to the loss through keeping, the decay does not amount to 1 per cent. with me, and in a good store loss of weight is very small. Annie Elizabeth is one of the best Apples for market purposes, being worth 1s. 9d. per bushel more than Bramley's Seedling. Whether the gross return per acre would equal Bramley's is very doubtful, as it is not such a sure bearer, although in a good season it often carries a heavy crop. The tree is a vigorous grower, and keeps very healthy. As a baking Apple, it is very useful, as it keeps its shape, which Bramley's will not do. Newton Wonder is another excellent keeper, and one that bears well, especially when grafted on established trees; I have a good quantity of it at present that will keep for a considerable time longer. It is a splendid cooker, and it is also very useful for dessert at this time of the year. Hoimead's Pearmain is not grown so largely as its merits deserve; it is very firm and fresh at present, and has the great merit of swelling out to an even size under good cultivation; it is a good cooker. I have a note of it cooking well on May 4 in a previous season. An Apple which much resembles the last in appearance, and other good qualities, is Hambling's Seedling; it promises to be a more vigorous grower, but I cannot speak decidedly as to its cropping qualities at present, as my trees are but small. The above are the best of the late-keeping, cooking varieties. Mr. Molyneux speaks of Cox's Orange Pippin being finished at Christmas! I have only lately commenced to use it, and have a fine lot in the store-room. I cannot give the market value, as mine are for private use, but it would range from 6s. to 9s. per dozen. Anyone who had a few bushels of this variety now would possess a small goldmine. No Apple imported from British Columbia or anywhere else can equal it for flavour, neither will any other fetch as much money in the market. It is an intermittent bearer, but in this district is not subject to canker as it is with *Southern Grower* (see p. 97). I find it repays good cultivation, even in the case of trees 30 to 40 years of age; it requires watching carefully as to its latest time for keeping, as it often commences to decay at the insertion of the stalk. I am surprised that Barnack Beauty has not made more progress as a late-keeping dessert variety; it keeps here until June, is of excellent flavour, and has a nice red colour on the sunny side. The principal point in regard to profit is that it bears heavily and regularly; if any trees bear here in a scarce year, Barnack Beauty is sure to be one of them. I do not recommend it for standard trees, as it crops so heavily, and the fruit is inclined to be small; but on the Paradise stock, with good cultivation, it grows to a good size. No doubt, in the South, it would be larger on standards than it is here in the Midlands. Another good late variety is Duke of Devonshire. At the present time this is very good in quality, and will keep for several weeks longer; it is a much better Apple than either Baumann's Reinette, Lord Burghley, or Sturmer Pippin, for a private garden (the last variety is of no use whatever in this district), but

Duke of Devonshire is marked with russet, and is without colour, and probably of no use for sale; it is a good cropper, but requires much care as to time of gathering, or it shrivels. It has another fault, in a tendency to drop from the tree prematurely during strong winds, and is therefore not adapted for growing as a standard. This latter point—care as to time of gathering—cannot be over-emphasised, if Apples are to keep well until late in the season; another important matter is a low temperature and an even one in the store-room; and the fruits must not be laid in heaps 3 feet deep, as I have seen them in Kent in my early days. I do not know if the practice there has improved since then—let us hope it has—but I am quite certain the majority of our trade growers have yet very much to learn before their produce is put on the market in as good a condition as the foreign produce. W. H. Piers, *Belvoir Castle Gardens, Grantham, February 25.*

—In connection with the interesting notes on late-keeping dessert Apples, I quite agree with Mr. A. C. Bartlett as to the good qualities of some of the Russets, and also of Cornish Gilliflower. There are two further varieties that I think are worthy of mention as late dessert Apples. The old Cackle's Pippin, though not a highly coloured Apple, is of good flavour when grown on young trees and the fruit thins. Dutch Mignonne is to be recommended, as it keeps well, comes in after Christmas, and is an Apple of good appearance, with a really good flavour; both varieties are good growers, and as a rule the trees bear well. J. J.

APPLE NEWTOWN PIPPIN.—In the discussion on late dessert Apples, I have seen no mention of this famous American variety, although it must have been tried in a good many gardens. Here, on a wall facing to the west, it behaves very well, and furnishes good crops of average-sized fruits in most seasons. In point of flavour, the fruits may not be quite equal to the best of those imported, but in its season, namely, February and March, it is generally as good as most varieties. The three best and most useful dessert Apples here are James Grieve, Cox's Orange Pippin, and Adams's Pearmain, and these are in season from October to March. J. G. Littlecote, *Hungerford, Berks.* [Our correspondent sent several fine fruits weighing $\frac{1}{2}$ lb. each. The skins were as clear and fresh as possible, and the fruits were quite agreeable eating, but the quality was not quite equal to imported fruits of this variety.—Eds.]

SKIN POISONING BY IVY.—Having read the paragraph on p. 139 respecting a case of poisoning by Ivy, I wish to give my experience of a similar case. Having a good deal of Ivy about my garden I instructed a jobbing gardener to cut it, which he did, but to my horror the poor fellow looked as though he had been stung by a hive of bees, and he said he was affected all over. Never again will I allow him to touch Ivy. He was a new hand, and a healthy looking young man. M. E. T.

—I was much interested in the note upon skin poisoning by Ivy. Some years ago after cutting Ivy I was troubled with exactly the same kind of thing, namely irritation of the skin on face, head, and forearm, which eventually broke out in large sores. I suffered more particularly round my eyes and on my forehead. This kind of thing happened two years in succession, although not quite so severe the second season as the first. I have trimmed Ivy on a great many different occasions, but have never felt any ill effects excepting the two occasions already mentioned, when, I might add, I was engaged at the work for 10 days at a stretch. The trouble commenced after the second day, and was probably aggravated by me continuing the work. I have never known anyone in those gardens or elsewhere to be troubled from the same cause. W. C. Leek, *Ryhall Hall Gardens, Stamford.*

BROWN OAK.—I think that Mr. Dawson is assuming too much (see p. 140) when he assures us that it is "as completely in our hands to grow such wood as it is for a florist to grow a new Rose or Apple." No doubt it would be interesting to attempt to produce brown Oak by grafting, as he suggests, but to assume that brown Oak is a

sport as he does is certainly not justified by the very limited knowledge which we have at present about this beautiful wood. Four years ago I published what little reliable knowledge I had been able to obtain on the subject in the *Trees of Great Britain and Ireland*, pp. 337-339. For years before, and ever since that time, I have taken every opportunity to learn more; but the various causes which, singly or in combination, produce brown Oak are still doubtful. It has lately been suggested that iron in the soil may be the cause, but if this is true in some cases, it will not explain what I have observed, namely, that the change of colour which usually commences at the ground and extends upwards, sometimes commences above and extends downwards. And if it is true that in some places quite young Oaks have their heartwood brown as soon as they form any, it would seem more possible to reproduce this peculiarity by sowing Acorns from such trees than by grafting. I should be glad to see Oak timber of a dark olive green colour, as mentioned by Mr. Dawson, as it is quite unknown to me in nature, though I have often seen it stained that colour. H. J. Elwes, *Colebourne.*

RHODODENDRON BARBATUM.—The mildness of the present season in this locality is easily observable, and shows itself, in particular, where the early flowering Rhododendrons are concerned. In Lord Annesley's gardens at Castlewellan, several species are now flowering with exceptional freedom, and the absence of frost has tended to the development of blooms perfect in form and colouring. But even here, in critical surroundings, *Rhododendron barbatum* has no serious rival when at its best. This species is represented in these gardens by several fine specimens, but one well-branched plant, in particular, standing 10 feet high and carrying more than 80 expanded trusses of from 12 to 18 flowers each, presents to-day a picture which would be striking at any season of the year, and is certainly very remarkable in February. The deep-green leaf-colouring provided a singularly suitable setting for the brilliant blood-red flowers, which a glimpse of sunshine only tended to intensify. The plants here are all on their own roots, and are well placed to escape the early morning sun, and they are screened from heavy winds by surrounding tree-growth. Beyond occasional top-dressings and thinning out of dead wood, they require but little attention, and, though now more than 20 years old, they continue to produce an abundant supply of fresh growth each season. *R. vulgare* has already opened the first of its many buds, and gives promise of a great show of flower in the immediate future. Such species as *R. argenteum*, *edilatum*, *Thomsonii*, *Campbellii*, *campanulatum* and *niveum* are especially well set with flower-buds, and, should the weather conditions remain favourable, they may be relied upon to bloom freely later on. These gardens are now under the management of Mr. T. J. Ryan, who is successfully carrying on the work so ably begun by his father, and the enviable reputation of the place promises to be well maintained in his hands. H. Armitage Moore, *Castlewellan, Co. Down, February 27.*

EXPORTATION OF PLANTS TO NEW ZEALAND.

—Can any reader of the *Gardeners' Chronicle* tell us who is the authority in this country capable of giving a certificate relating to the freedom from disease of plants intended for exportation to New Zealand? Twice we have received notice from the Department of Agriculture at Auckland, N.Z., that in future a certificate must accompany anything in the plant way sent to that country:—"Signed by an officer of the Department of Agriculture in England or other authority performing the functions relating to horticulture." We may say we invariably send with New Zealand consignments the usual Phylloxera certificate, declared and signed before a magistrate, but this evidently does not satisfy the overseas Department of Agriculture, and we are sure there must be others besides ourselves who would be glad to know who can certify. It seems to us that those who grow the plants best know if they are diseased, and if these are firms of honourable repute, and they declare them clean, the declaration is most likely correct. In the case of dormant trees and tubers, such as are usually exported, an outside authority who had never seen them in their growing state would have a difficulty in ascertaining whether they are free of disease or not. Keynes, Williams & Co.

THE PROPOSED DAFFODIL SOCIETY.—Previous to the meeting held on February 14, I supported the proposal (by letter) to form a National Daffodil Society on the grounds that there was scope for work over and above the functions of the R.H.S. Daffodil Committee as at present constituted. From what passed at that meeting, however, and on further inquiry, I gather that such is not the case. I understand that the R.H.S. may be both able and willing to undertake all that is necessary to satisfy the requirements of those interested. This, to my mind, would be far the more preferable solution of the matter. But it is probable that the support given by others to the national project has likewise been conditional, and on more or less the same grounds, tacitly or otherwise. Our chief requirements, I think, are: (1) In a general way we want a central organisation to focus the work of all the societies scattered throughout the country, to encourage their extension, and to link them together by affiliation, while leaving each absolutely independent. (2) A Daffodil exhibition in London each year. (3) The publication of an annual, both for the dissemination of matters of current interest and as a medium for the permanent records. (4) The compilation of an authoritative list of varieties—kept up-to-date—with parentage and their raisers, as far as this is possible (and while it is possible), which has already been arranged for. There are other things, less pressing, which I hope eventually to see the R.H.S. Committee take up. It should be possible to arrange for a series of illustrations (as for Orchid hybrids) as a record of the more notable varieties. Experimental work might also be carried out at Wisley—or by the co-ordinated labours of private members—under the direction of the committee or a sub-committee. The committee should also continue their especial function of guiding the improvement of the Daffodil by the wise and impartial discrimination of their awards, which has hitherto constituted their great value. Some of these things cost money, and if it should be necessary, I see no reason why there could not be a special and extra subscription from those members of the R.H.S. who were interested and wished to participate in the results of these extra labours of the committee—the Year Book, List of Varieties, the Annual Show, Reports, &c. Since the R.H.S. Committee is already in existence, and is certainly the most competent and appropriate body to undertake all these things, and could carry out all of them as well, and some of them better than a separate National Society, it would seem in every way desirable that it should be retained as the head and central body. With the R.H.S. Committee then as the national centre, the scheme would be ideally filled by the eventual formation of a few large societies, which would look after the exhibition side of the business throughout the country, in the same admirable way that the Midland Society now does. Each of these societies should embrace an equal seasonal area, grouped round already existing centres and forming natural and recognised divisions. A South-western, a Southern Counties, the Midlands, an Eastern Counties Society, and so on. There would still be scope for smaller local societies and shows. With the R.H.S. as a centre, every encouragement would be given to the formation of large district societies. But if a separate National Daffodil Society should be formed there would certainly be an opposite tendency for the now large societies to break up. Even the Midland Society would be injured, or absorbed into the National Society; and though this has been openly advocated by some, I feel sure most of us would regard it as a retrograde step. It is not at all sure either that it would not even practically destroy the R.H.S. Daffodil Committee—it would at any rate inevitably diminish its authority and prestige—and that would be an even greater loss. Furthermore, a single great National Society, with one large annual show, could not suit all the wide variation of season throughout the country and the wide range of the period of flowering of the different varieties of Daffodils in the different seasonal areas, beginning in early March (in the southern and lasting till nearly the end of May in the northern and eastern counties). It, to meet this, it was proposed for the National Society to hold three or four large shows in the different centres of the country, that would be much less satisfactory than that such shows

should be organised and held, each in its own centre, by the societies themselves. In this latter case, with several strong Daffodil societies of equal seasonal area, each holding large exhibitions, on successive dates, to suit mid-season varieties—directly under the aegis of the R.H.S., but otherwise quite independent—exhibitors would have the opportunity of showing the whole range of varieties grown under natural conditions. A far greater and wider stimulus would thus be given to the cult of the Daffodil than would be possible under the excessive centralization that a National Society would involve. *A. J. Bliss, Kent, Surrey and Sussex Daffodil Society.*

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

FEBRUARY 28.—*Present:* Mr. E. A. Bowles, M.A., F.L.S. (Chairman); Sir Everard im Thurn, Sir John Llewelyn, Rev. Canon Fowler, Prof. Boulger, Messrs. E. M. Holmes, A. Worsley, J. T. Bennett-Poe, J. Fraser, H. J. Elwes, R. Hooper Pearson, W. C. Worsdell, W. Hale, J. W. Odell, and F. J. Chittenden (hon. sec.).

FIG. 71.—*SAXIFRAGA X BURSICULATA.*

Galanthus hybrid (?).—Mr. BOWLES showed drawings of the *Galanthus* exhibited by Mr. ELWES at the last meeting, and reported that in structure and appearance it approached certain hybrids of *G. Elwesii*. He thought it might be a hybrid of that species with *G. caucasicus*, but the characters shown by seedlings which Mr. ELWES said would probably flower next year would throw further light upon the parentage. Mr. ELWES showed a photograph of a group of plants growing in his garden.

Hippeastrum calyptratum.—Mr. WORSLEY showed flowers of the unspotted form of this species from his garden.

Lupinus racemosus.—Mr. ODELL showed flowering shoots of this plant, and commented upon the peculiar method of pollination.

Gall on Willow.—Mr. FRASER brought stem galls upon *Salix purpurea* Lambertiana similar in appearance and structure to those produced on *S. aurita*, &c., by the dipterous *Cecidomyia salicis*, and which he thought had probably been formed by that insect, although they were usually found attacking only willows.

Hybrid Hippeastrum.—Mr. ELWES showed flowers from plants the result of a cross between

Hippeastrum equestre and *H. x "Sir William."* The plants flowered at two years of age, and bore red flowers (as usual with equestre crosses), varying, however, in shade and markings. Mr. ELWES undertook to report later upon these hybrids when more of the same cross had flowered.

Fasciated Orchid.—Mr. GURNEY WILSON showed a plant of *Brasso-Cattleya x Fowleri*, in which one of the pseudo-bulbs had forked before flowering, and both forks appeared likely to flower. Mr. WILSON remarked that malformations of plant and flower appeared to be much more frequent in trigeneric hybrids than in crosses between the species.

Narcissus cyclaminus x N. minimus.—Mr. BOWLES showed a plant of this cross raised by Mr. CHAPMAN.

Saxifraga x Bursiculata (see fig. 71).—A hybrid between *Saxifraga Bursieriana* ♀ and *S. apiculata* ♂ came from Mr. E. H. JENKINS. The plant was remarkably vigorous and free flowering. In the length of the peduncle, its greenish colour, and in the form of the calyx, the hybrid resembled *S. apiculata*. The whiteness of the corolla and the crimped edges of the petals called to mind *S. Bursieriana*, as did the spiny and glaucous characters of the foliage. In the size of the rosettes and the horizontal spreading of the leaves it resembled *S. apiculata*. The other seedlings raised from the same capsule included two yellows, one poor and weedy looking, and 10 plants indistinguishable from *S. Bursieriana* (see p. 141).

Beetle boring bark of Austrian Pine.—Canon ELLIOMBE sent a piece of the bark of *Pinus austriaca* bored by a beetle, which Canon FOWLER reported upon as follows:—"The borings of the beetle in the bark of the Austrian Pine are very old, and there is no trace of either beetle or larva to be found. I think it probable, however, that the injury was done by *Hylastes ater*, which attacks various kinds of Pine, both roots and trunk; it is a rather common and widely distributed insect in England, but apparently commoner in Scotland. This is, however, surmise, as it is impossible to be certain; the wood looked as if it had been used for a pergola or fence of some sort, and was quite dry and ancient."

Double Arum.—Miss MUSGRAVE sent a specimen of *Richardia africana* having the leaf next to the inflorescence wholly white except for a slight green mottling. Miss MUSGRAVE said that the same plant had produced similar growths in former years.

Fasciation in Primula malacoides.—The Venerable Archdeacon DONNE sent a water-colour drawing of *Primula malacoides* with a fasciated stem.

LINNEAN SOCIETY.

MARCH 2.—At a meeting held on this date, Mr. C. E. Salmon showed British specimens of *Lepidium neglectum*, Thell., and *L. densiflorum*, Schrad. Mr. F. N. Williams, Mr. E. G. Baker, and Dr. O. Stapf discussed the probable origin of these forms, and Mr. Salmon replied.

Mr. H. W. Monckton showed a series of lantern slides from photographs taken during his visit last autumn to Sweden as a delegate on behalf of the Society to the International Congress of Geologists, especially those taken at Upsala, some of which showed places connected with Carl von Linné, including a front view of his house in the old Botanic Garden.

Mr. H. R. Darlington commented on the modern use in Sweden of the German prefix "von."

The general secretary then showed a supplementary series of lantern slides, chiefly from old prints, concerning the history of the old botanic garden. He stated that when Linné and Rosén had exchanged chairs in January, 1742, and the former had thereby become prefect of the garden, he took immediate steps to rearrange the garden, provide glass-houses, and rebuild the house attached, which belonged to the prefect. The last slide showed the old Poplar close to the entrance, the only specimen which can be regarded as coeval with Linné, inasmuch as the Laurels and a few other veterans had been transported to the new botanic garden early in the 19th century.

Dr. A. Strahan, F.R.S. (visitor), Mr. H. N. Dixon, Dr. A. P. Young, and Dr. James Murie joined in the discussion.

SCOTTISH HORTICULTURAL. LECTURE ON SWEET PEAS.

MARCH 7.—At the usual monthly meeting in Edinburgh on the above date, the president, Mr. W. H. Massie, occupied the chair, and there was a very large attendance. Mr. W. Cuthbertson was the lecturer, and his subject was "A talk about new Sweet Peas."

Mr. Cuthbertson said that prior to 1901 there were no Spencer or Waved Sweet Peas. Accepting the form of the flower as a standard there were two old types, which are still largely grown. The erect-standard type is well represented by Triumph and Prince Edward of York.

The hooded-standard type by Lady Grisel Hamilton and Dorothy Eckford.

These forms still appeal to a number of florists. The new Spencer varieties are to them anathema, just as the fancy Pansies were to the lovers of the Old English or show Pansies. But in horticulture, as in other things, the march is forward not backward.

How pleasant it is, too, when one feels that the forward march is a profitable one—profitable, not only in the sense of increasing the beauty and usefulness of the flower, but profitable also in so extending the area of interest that, to many,

two or three promising things, the rest being rubbish. The good ones I crossed with Prima Donna, and the next season, that was 1900, there was one plant among the seedlings much stronger than any of the others, and which flowered much later than the other varieties. That proved to be the original 'Countess Spencer.' I just managed to save five seeds—one pod only. The following spring, after sowing them, I lost three of them in one night owing to mice. The stock was thus reduced to two plants, but from them I saved 90 seeds. It was from these plants that I exhibited the flowers for the first time. In 1902 I sowed all the seeds, every one came true, but, owing to it being a wet summer, I only managed to save about 3,000 seeds, 2,200 of these were sent in 1903 to America to be grown for stock by Mr. Sydenham. What came back from America was a mixture of all sorts, no more like my true Countess Spencer than day is like night. With me Countess Spencer has never sported to this day. It has thrown reversions: that is, it has reverted to its parents, such as Lovely and Triumph, and on rare occasions to Prima Donna, but nothing else. To my mind, that is not sporting. That is all there is to tell about the origin of Countess Spencer."

PURITY AND FIXITY OF STOCKS.

According to the Sweet Pea Annual for the current year just over 300 trials of Sweet Peas were made at Guildford last year for the society by the late Charles Foster at the "Times" Experimental Station. Only 129 of that number were true stocks. No one knows better than I do the difficulties confronting seed growers and raisers of novelties, but no apologist could ever explain away such a disparity as these figures represent. True a very considerable number were novelties, but novelties ought to be fixed before they are unloaded on the British public.

There are two ways known to me of obtaining new varieties of Sweet Peas. First, by selecting and fixing variations; second, by cross fertilising approved varieties, and selecting new varieties from the progeny. A very large number of varieties on the market come under the first heading. I will give you one example. The well known "Helen Lewis," which obtained the silver medal of the National Sweet Pea Society in 1905, was brought forward in 1904 by Mr. Watson. That same year my firm found it among our Countess Spencers, and so did Mr. Sydenham. We both named it "Orange Countess," but, to avoid duplication of names when the Society gave the medal to Mr. Watson, we both withdrew our names, and united on "Helen Lewis." That has been the history of many other varieties, but the practice of withdrawing names has not been largely followed, hence we find similar varieties offered by different firms under different names. This is just where the list of synonyms, or "too much alike varieties" published by the National Society, comes in useful. I cannot commend it too highly.

The other method of raising new varieties, namely, by careful cross breeding, is the one which is going to give us the finest varieties in the future, but it can only be undertaken by those who have considerable scope and facilities to carry it on. Let me trace the process from the beginning. One decides what cross one is going to make. For the sake of illustration, let it be "Countess Spencer" x "King Edward." The pollen of "King Edward" is transferred to the stigma of "Countess Spencer." That sounds very simple, but it is well to try to realise what it covers. The pollen grain conveys a representation of all the constituent parts of a plant of "King Edward." Professor Bateson somewhere likens the process of cross fertilisation to the mixing of ingredients, represented by taking drops of fluid from a given number of bottles to represent the female side, with drops of fluid from another set of bottles representing the male side. This, at least, conveys clearly to the mind that in cross fertilising so simple a thing as a Sweet Pea, the characters of both parents are commingled. They are, or should be, commingled for a purpose, unless one is taking a sporting chance of a new break.

We now know, thanks to Mendel's law, but Henry Eckford must have known it long before Mendelism was published, that no reliance can be placed on plants of the first generation. They are only unfixd character carriers, but they follow certain well defined and pretty fully understood laws. For example, in the cross just referred to, there will be no waved flowers. They will be all reds and all King Edward, or old type. Seed saved from them, and sown out the following season, will give a wonderful revelation. There will appear many reds and pinks, the same in form as "King Edward," and there will appear a few true "Countess Spencer," and a very few "Countess Spencer" in shape, but red in colour. Time will not permit me further to go into this, except to say that plants which give the novelty desired should be tied up separately and saved separately, and the following season grown in quite distinct lines. It may be, it will be found, that many will vary again, but the ones which remain true must again be bred from single plants, and this should go on for several years until one is satisfied that the stock is homozygous, or breeding true to the character desired.

Mr. Cuthbertson described in the same way the breeding of "Clara Curtis," the best waved primrose from "Countess Spencer," crossed with "Mrs. Collier," and materially aided his remarks by exhibiting a series of coloured drawings. Continuing, he said, no one now used hooded or old type flowers to cross with Spencers, unless there

(Photograph by W. J. Vasey.)

FIG. 72.—GROUP OF RHODODENDRON INDICUM (AZALEA INDICA), EXHIBITED AT THE R.H.S. MEETING ON FEBRUARY 28 LAST BY MR. L. R. RUSSELL, RICHMOND.

the task of meeting the demand for seeds, &c., has become a lucrative business.

To the annual exhibition of the National Sweet Pea Society, in the month of July, 1901, Mr. Silas Cole, gardener to Earl Spencer, Althorpe Park, Northampton, brought a new Sweet Pea, which he named "Countess Spencer." I can see it before my mind's eye to-night, as well as I saw it that day, 10 years ago, in London. Its novelty and beauty captivated everybody, and it was unanimously awarded a first-class certificate.

I will show you that this new introduction made possible the great modern development of the Sweet Pea, and I think the name of Silas Cole will rank high in the annals of the Sweet Pea. It is worthy of being placed alongside that of Eckford. Quite recently I had a long letter from Mr. Cole, in which he told me fully how he raised "Countess Spencer." It is as follows:—

"With respect to the origin of 'Countess Spencer,' I will tell you what happened. Being always very fond of Sweet Peas, I turned my attention specially to them in 1898. That summer I crossed Lovely with Triumph, saved the seed, and the following year, 1899, there were

Why "Countess Spencer" appeared just at the moment it did will never, I fear, be known. It was the intention of the late Dr. Dixon Savill to try to raise "Countess Spencer" *de novo* had he lived by doing Mr. Cole's work over again. One thought strikes me in connection with the matter. Mr. Cole crossed his F₁ plants with "Prima Donna." I think this is an important point. It may have furnished just the needed extra excitement to cause the new form to "come forth."

Another type of waved Sweet Pea made its appearance a few years later than the Countess Spencer. It was raised by Mr. W. J. Unwin, of Histon, one of the most careful trade growers we have, but it lacked the massive proportions of Cole's Countess Spencer, and has, therefore, not been utilised to anything like the same extent for breeding, hence, all, or nearly all, the best modern Sweet Peas are Spencers or Giant Waved.

Mr. Cuthbertson passed in review all the named varieties which now stand at the top of the National Sweet Pea Society's selections, and also novelties which are likely to be candidates for a place in these selections in 1911.

still existed colours in the old type which do not yet occur in the waved, and he did not know of many. Modern raisers were crossing the very best waved types with the view of obtaining new colour combinations, as they were yet a considerable way off "the blue" of *Salvia patens*, the scarlet of the *Geranium*, and the yellow of the *Coreopsis* in the Sweet Peas.

A good discussion followed.

NATIONAL HARDY PLANT.

FEBRUARY 28.—A meeting of the Council was held at the Hotel Windsor on the above date. The Executive Committee reported that they had been in communication with various societies, and were co-operating with the York Gala, Cardiff, and Lemington Societies, and they hoped to cooperate with the new North of England Horticultural Society. They recommended that the *Gardeners' Magazine* gold medal and £3 cash be offered as 1st prize, a silver-gilt Coronation medal and £2 cash as 2nd prize, and £1 3rd prize, for a special class for an exhibit of hardy plants of not more than three kinds arranged in the form of a circular bed upon ground space of not less than 6 feet and not more than 8 feet in diameter, to demonstrate the value of herbaceous plants for bedding purposes. An edging of some other hardy plant may, at the discretion of the exhibitor, be used to heighten effect. A silver-gilt Coronation medal will be offered for the best exhibit of Alpines at the June show of the North of England Society if arranged. It was also recommended that a silver-gilt Coronation medal be offered to the Cardiff Society for the best exhibit of hardy plants or flowers in the show, to be awarded by a deputation appointed to attend. The report was adopted. It was resolved to issue a special circular appealing for members.

Mr. GULF of Penryn and Falmouth, exhibited a new hardy Primula (*P. Winteri*) from the Himalayan Mountains snow-line, 12,000 feet elevation. (First-class Certificate.)

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

(LIVERPOOL AUXILIARY.)

MARCH 3.—The tenth annual concert, under the auspices of the Liverpool Auxiliary, in aid of the funds of the Gardeners' Royal Benevolent Institution, took place on the above date. Mr. Harry J. Veitch presided. Previous to the concert, Mr. Allan H. Bright, J.P., entertained the chairman and other friends of the society at dinner.

The concert room was embellished with plants and flowers, contributed by various friends. During the evening the chairman delivered an address on the work and objects of the institution, and referred to the good work done by the Liverpool Auxiliary. Mr. G. J. Ingram, the secretary, also addressed the meeting. The officers of the Liverpool Auxiliary are Messrs. C. A. Young (chairman), J. Finnigan (vice-chairman), A. J. Crippin (hon. treasurer), and R. G. Waterman, Woolton (hon. secretary).

ADIANTUM FERN: *W. A.* The pests attacking the Ferns are common weevils. Trap them with pieces of vegetable, and hunt them at night-time, when they feed.

BEAN WEEVIL: *C. Anderson.* The seeds are infested with the bean weevil (*Bruchus rufimanus*). The larvæ of this insect enter the Beans when they are quite young, and the weevil therein completes the whole of its life-cycle. On no account should the seeds be planted. The weevils can be destroyed by the fumes of bisulphide of carbon.

COLD STORAGE OF BULBS: *H. Smith.* Thousands of bulbs of Liliiums, chiefly such as *L. longiflorum* and *L. Harrisii*, are now stored in cold chambers for several months, and suffer no injury in the process. Bulbs that have been kept as long as 18 months in a dormant condition in these refrigerating chambers force

well, and produce magnificent blossoms. The temperature maintained is from 26° to 31° Fahr., but sometimes a few degrees above the latter figure may be maintained for special reasons. The temperature, however, is never allowed to rise above 56° F. The bulbs are usually stored away exactly as they arrive in the stout wooden boxes in which they are packed in the soil, this method being a convenient one. Some growers, however, overhaul the bulbs on arrival, pick out any diseased ones, and afterwards repack the sound ones, prior to sending them to the cold storage chambers. Bulbs retarded now could be forced easily next September or October. The cost of storage is about one penny per cubic foot per month, so that a box measuring 3 feet long by 2 feet wide and 1 foot deep would cost 6d. a month.

CUCUMBER DYING: *C. H.* There is no disease due to fungi or insects present. The trouble is due to some cultural defect, apparently that of maintaining too much moisture in the atmosphere.

CYANIDING A VINERY: *H. J. W.* Reduce the temperature in the vinery to 50° or 55°, and employ 1½ ounce of sodium cyanide, 3 fluid ounces of sulphuric acid, and 9 fluid ounces of water for each 1,000 cubic feet contents, allowing an exposure of 40 minutes. The foliage should be dry when the cyaniding is done. You can obtain the necessary chemicals from the horticultural sundriesmen.

HOYA BELLA: *T. B.* A suitable compost for this stove plant consists of three-parts fibrous peat and one part fibrous loam, with some small pieces of charcoal, sandstone, and plenty of coarse sand added. Use the soil in a fairly rough condition, not breaking the loam and peat in too small pieces.

IVY "DISEASE": *W. Chitty.* The white, flocculent patches on the Ivy are the empty egg sacs of a species of scale insect (*Lichtensia vilumii*). The sacs are, for the most part, ruptured, and, if examined with a lens, may be seen to consist of waxy or mealy material, in which are incorporated the empty egg shells. The life-history of this insect is, briefly, as follows:—The young ones hatch in the late summer, feed for a time, and then hide themselves under the loose bark, remaining in a dormant state in such situations throughout the winter. In late spring they become active, crawling about the stems and leaves to feed; when mature, they closely resemble the young of the soft brown-scale, so common on cultivated plants. At this stage the female envelops herself in the white, flocculent sac, lays her eggs in it, and then falls to the ground and dies. In addition to the *Lichtensia*, there are also present a few other scale insects related to the mealy bugs, evidently a species of *Pseudococcus*; but these are immature. Spraying with paraffin emulsion would check the increase of these insects, but it is very doubtful if they can be exterminated by the application of insecticides, as they are so well protected by the accumulation of dirt that it would be impossible to reach all of them by spraying.

NAMES OF PLANTS: *J. Tomlison.* 1, *Lonicera Stanbushii*; 2, *Ceanothus*, probably *rigidus*; 3, *Azara microphylla*; 4, *Daphne pontica*; 5, *Erica carnea*; 6, *Taxus canadensis*.—*Taxus*. 1, *Taxus baccata* var. *elegantissima*; 2, *T. b.* var. *fastigiata* (probably); 3, *Cupressus obtusa* var. *aurea*.—*Ulex*. *Grant*, *Cedrus Libani*. The first fortnight in May is a good time to plant Yews and Hollies.—*J. H. Cromer.* 1, *Hebea Helix* var. *minima*; 2, *Erica carnea* var. *alba*; 3, *Erica carnea*; 4, *Buxus sempervirens argentea marginata*; 5, *Hebea Helix* var. *amurensis*; 6, *Acteaba japonica* var. *nana*, female form.—*W. J. C.* 1, *Cupressus Lawsoniana*; 2, *Juniperus virginiana*; 3, *Thuja plicata*; 4, *Cupressus Lawsoniana*; 5, *Cotoneaster microphylla*; 6, *Cryptomeria japonica* var. *elegans*; 7, *Cupressus Lawsoniana* var. *lutea*; 8, probably a form of *Juniperus chinensis*; 9, *Taxus baccata* variety; 10, *Sequoia gigantea*; 11, *Thuja occidentalis* var.; 12, *T. orientalis* var.—*E. C. Ashford.* *Odontoglossum gloriosum*. The resemblance of this plant to *O. Andersonianum*, which you note, is because *O. Andersonianum* is a natural hybrid, and *O. gloriosum* one of its parents.—*Sub-*

scriber, Norway. The Fern of which you send a frond was introduced from the neighbourhood of Port Elizabeth some years ago as *Adiantum O'Brienianum*. A similar species came from Japan, as *A. Mariesii*, and both are cultivated for market purposes under various names. The botanical affinity seems to be nearest to the widely-distributed *A. Capillus-veneris*, though, in size and amplitude of the frond, it approaches the tropical *A. tenerum*. The fronds last better when cut than those of most *Adiantums*.—*G. E. B.* *Miltonia Warszewiczii*, often called *Oncidium fuscum* and *O. Weltonii* in gardens.—*A. E. S.* *Dendrobium fimbriatum oculatum* and *Cyclogyne lactea*.—*A. W. G.* 1, *Galanthus Elwesii*; 2, *G. plicatus*; 3, *Populus alba*.—*C. L.* 1, *Oncidium flexuosum*; 2 and 3, *Cattleya Trianae*.—*Old Reader.* 1, *Omphalodes verna*; 2, *Anemone Hepatica*; 3, *Pulmonaria officinalis*. We do not undertake to name varieties of Violets or other florists' flowers.—*W. T. L.* *Dendrobium primum*.—*T. S. X.* 1, *Cypripedium Boxallii*; 2, *C. villosum*; 3, *Sedum carneum variegatum*; 4, *Peperomia arifolia argyrea* (*Saundersii*).—*G. H. H. W.* *Aselepis curassavica*.—*J. H. B.* *Dendrobium Brymerianum*.—*H. F. G.* *Crocus Madame Mina*.

NARCISSUS: *W. D. & Sons.* The plants are affected with yellow stripe, a bacterial disease. There is no remedy. It cannot be determined whether the bulbs were infected when planted, or whether they were planted in infected soil.

NECTARINE FLOWERS INJURED: *J. G.* The damage has apparently been caused by some insect or small animal seeking the nectar. There is no disease present.

NESTING BOXES: *T. W. B.* These can be obtained from the Selborne Society, 42, Bloomsbury Square, London.

PALM WITH INSECTS: *Enquirer.* The leaf you have sent us is infested with scale. Sponge the foliage thoroughly with some insecticide, rubbing as much of the scale off as possible without injuring the leaf. Paraffin emulsion, if made at not too great a strength, is suitable for destroying scale, or you might use Fir-tree oil.

PANCRATIUM UNHEALTHY: *L. T.* Most of the roots are completely destroyed by the bulb mite, which is present in great numbers. Four ½ fluid ounce of bisulphide of carbon on to the cracks through the hole at the bottom of the pot. This substance is highly INFLAMMABLE, and must be used with great care.

PELARGONIUM AND ASTER: *T. B.* Send the *Pelargonium* to some nursery firm, where it may be compared with the variety you mention. The *Aster* seedlings are probably attacked by disease. Send specimens to us for examination.

POULTRY MANURE: *Leguminous.* Fowls' dung is a valuable garden manure, and worth considerably more than farmyard manure. It should be stored in a shed to become dry, or mixed with dry soil and used fresh. Do not use it too freely to growing crops, as it is of a hot and fermentive nature. A dressing of 1 lb. to 2 lbs. to the square yard is sufficient.

RICHARDIA (ARUM) AND MARGUERITES: *H. R.* The spots on the *Richardia* leaves have been caused by moisture condensing and becoming chilled; no fungus is present. Spray the *Marguerites* with *Quassia Extract*, in order to render the leaves distasteful to the fly which lays the eggs that give rise to the mining larvæ.

SULPHIDE OF POTASSIUM: *A. C.* This fungicide is employed in solution, at a strength of 1 ounce of sulphide of potassium to 2½ gallons of water. Dissolve the sulphide of potassium (or liver of sulphur as it is known) in a quart of hot water, and then make up to 2½ gallons with cold water.

TELEMLY SWEET PEA: *T. W.* The variety you send is very pretty so far as we can judge from the flower received.

Communications Received.—*J. J.* (Thanks for photograph it is under consideration)—*H. G. C. W.*—*H. F. L.*—*F. J. C.*—*J. F. W.*, Holland—*Vincet veritas*—*D. M.*—*D. W.*—*W. H. W.*—*S. D.*—*W. F. THE PRUNING OF ROSES.

THE HYBRID TEAS.

WHAT a wonderful variety of this section of Roses we have now in our gardens, and how numerous are the forms of beauty to which we can adapt them! First, there are the climbing and pillar Roses, like Carmine Pillar and Climbing Mrs. W. J. Grant; next Roses to make big bushes—Gruss an Teplitz, Reine Olga de Wurtemberg, and Gustave Regis; then come tall, upright growers like Pharisæer and Mrs. E. G. Hill, and branching symmetrical bushes of the Caroline Testout type. Again we find Roses which perversely try to grow in a lob-sided panicle, proceeding from a single strong shoot, such as Joseph Hill and Mme. Abel Chatenay; and typical bedding Roses like Dr. J. Campbell Hall. Further, there are Roses like Ecarlate, which nearly approach the Chinas, and others very close to the H.P.s, of which I will take as examples John Ruskin and Gladys Harkness. We have also the singles, Simplicity, Irish Elegance and several others with the prefix "Irish," and the semi-double Theresa. Then there is Bessie Brown, impossible as a garden Rose, but indispensable for the exhibitor, and which, even in the garden, ought to find a place in some infrequently visited corner, to give us the one or two superb

specimen Roses we get in a fine season; beside these, there are Roses of the spreading, branching habit of the Lyons Rose—Miss Willmott is, I think, clearly right in holding that we ought to spell this Rose with an "s" to emphasise its distinctness from the Lion, a red climber; and, after all, this would accord with the English way of spelling the town from which the Rose takes its name—and Roses like Mildred Grant of short, stumpy, upright growth, usually with a single flower on the top, expanding to a small cabbage. Of Mildred Grant, a year ago I should have written "good for nothing but the exhibition box," but who can recall Mrs. Orpen's superb basket at the Botanic Show, decorated, if my memory serves, with nothing but Mildred Grant and Frau Karl Druschki, combined in so clever a way as to give a wonderfully soft and "pink" effect to the blush Rose, and deny that Mildred Grant, when not too large, and used with discretion, is capable of most artistic treatment? I do not remember whether the basket won the first prize. I hope it did, for the use of this beautiful Rose, as Mrs. Orpen arranged it, revealed a touch of genius. Perhaps no one but a past mistress in the art of floral arrangement—or the veriest tyro—would have dared to attempt it. Curiously enough, at the same show and within a few feet of Mrs. Orpen's wonderful basket, was to be seen another example of the decorative value of what are usually called exhibition Roses, in a dinner table arranged very effectively with flowers of Lady Ashtown.

But I must get back to my "muttons." Surely there is no class of Rose in the treatment of which my first rule for pruning—"never prune until you know the kind of Rose you are dealing with"—is of so much importance as in the case of the Hybrid Tea. I have enumerated many types, but might perhaps have added as many more, and each and all require somewhat different treatment. I will begin at the end of my list and work backwards. With Mildred Grant there is no difficulty; we simply take out the dead wood, of which there is generally a certain amount, and cut the live stems to the ground; if we leave one or two buds it will be sufficient; and Marquise Litta is another Rose requiring the like treatment. It follows, I think, that these Roses may be planted closely together—a foot apart will be ample. Somewhat similar will be the pruning of the Roses that approach the H.P. type; but, if desired, John Ruskin, which is a strong grower, may be tried pegged down. Ecarlate and Roses of a character tending towards the Chinas, may be pruned either hard or lightly. The latter course is generally advised, and at least for a few years they do very well in the borders with very little pruning after the first year; but in this case care must be taken to provide for the production of new wood by a system of thinning and cutting back some of the growths, or in a few years the old stems become hard and unmanageable. I think that these Roses should be pruned rather later than most hybrid Teas, and both hard and long pruning employed, of course, on different plants. When Ecarlate and Marquise de Salisbury are in beds I like to shear the outer plants right down, pruning those in the centre rather less severely. The last remarks will indicate the way to treat the bedding varieties Dr. J. C. Hall, Mme. Ravary, Duchesse of Wellington, Richmond and Augustine Guinoisseau, at least when they are used in beds. The amount of pruning they receive should be dependent on their

position in the bed. There are some Hybrid Teas, of which Lady Ashtown is an example, which make beautiful bedding Roses when their flowers are not grown too large, but when grown as exhibition Roses they hang their heads in a manner altogether pitiable and useless in the garden. I prefer to correct this tendency however, when they are grown as bedding Roses, not by less severe pruning, but by disbudding with discretion, which is quite effectual, and produces a better plant for the position in which it is being grown.

To produce a good effect in the garden, the singles must be grown into fair-sized bushes, and, so long as they are doing well, the pruning may be confined to the removal of misplaced and unripened shoots, together with a little shortening of the summer growth. The effect of the spring pruning should be carefully noted in August, and it ought to give a good indication of the treatment to be adopted in the following spring; an observation that applies to all Roses grown as large bushes. When the growth has not been satisfactory, it may sometimes be necessary to cut back somewhat severely in order to obtain stronger growth, even at some sacrifice in the current year.

The section of the Hybrid Teas which is one of the most difficult to treat satisfactorily in pruning, contains those Roses which, in their second growth, tend to throw up a single strong shoot in the form of a panicle growing out at one side of the plant. The Rose usually behaves satisfactorily in the summer or first blooming, but, after this, a stout shoot makes its appearance, and seems to absorb all the growing energy of the plant. Joseph Hill, Mme. Melanie Soupert, and Mme. Abel Chatenay are examples of this type, but there are several others. If some measures are not taken to counteract this tendency the plants get more and more lob-sided. The first two Roses are often grown for exhibition, and where this is the case we may perhaps only be concerned to cut hard back to a promising bud, but where the appearance in the garden is the chief consideration some other method should be tried. In the case of Mme. Abel Chatenay something may be done by partially pegging or tying down the stems left after pruning to induce growth from the base of the plant, but the growth of the other two, particularly of Joseph Hill, is usually too stiff for this method of procedure. Mons. Vivian Morel recommends that when the stout shoot is seen to be starting in the summer it be pinched back to within 2 or 3 inches of the stem, when, instead of a single panicle, a fair number of flowers on moderately long stalks are obtained. This is often successful, but I find it is not quite so easy to catch the stout shoots at the right moment as it is to write about doing it. Short of this, the only thing to do is to encourage the plant to get back to a symmetrical attitude by pruning to the buds most likely to effect this, and afterwards by stopping buds which are making their way in the wrong direction.

Roses of the vigorous branching habit of Caroline Testout and the tall, upright growers like Pharisæer may be considered together. In both cases much will depend on the amount of room available and the character of the bush we wish to obtain. By leaving the best shoots about a foot long the second season, and afterwards pruning back to three or more eyes of the growth of the previous year, cutting to a bud pointing outwards and clearing the centre of the plant,

fine specimen bushes may be built up which will generally last for many years. It is quite worth while growing some Roses in this way for the effect they produce in the garden, but there will often come a time when the summer growth begins to get less satisfactory, and, indeed, may almost cease, and an examination of the stem near the ground will probably show an unsatisfactory condition of the bark. Then there is nothing for it but to dig up the plant and begin again with a young one. These Roses may also be treated with good effect by the severe method of pruning practised with the H.P.s. and are then apparently less liable to suffer from the evil I have described. Hard pruning will, of course, be adopted where exhibition flowers only are desired.

Now for the big bushes. There are some H.T.s that seem only to look and flower their best when grown as big free bushes. I think this applies to Gruss an Tepfritz, Gustave Regis, and (except when it is grown as a climber) to Reine Olga de Wurtemberg, and they are well worth growing in this fashion. Here pruning may for the most part be confined to a little thinning and snipping back of old flower-stalks. However, before the plants get old and the stems too hard and dry, whenever good young shoots are seen proceeding from anywhere near the base, it is well to cut one at least of the old stems right back to these and so renew the vigour of the plant.

Lastly come the climbing and pillar varieties: three of the most beautiful of these, Climbing Mrs. Grant, Climbing Papa Gontier, and François Grouse are at their best on a wall, but when not so grown it is of the first importance to remember that these Roses and, in fact, all the Hybrid Teas—and there are at least a dozen first-class Roses for the purpose in this section—tend to become leggy and bare at the base when tied up to a post. Steps must therefore be taken to prevent this. The most effectual thing to do is to untie the stems at pruning time and bend them down as near the ground as can be done without breaking them, leaving them in this position till the buds at the base have started into growth, when they can be retied to the pillar. Another plan, when there are enough stems, is to cut them to different heights. Thus, if you have eight stems, cut two to within a few inches of the ground, and the rest at distances a foot apart, only allowing one to reach the top of the pillar. It is often well to combine both these plans of treatment.

The pruning of H.T.s on wall, arch, and trellis will be confined to taking out shoots where they are not wanted and cutting out old stems whenever there is a chance of substituting young growths or allowing them to develop. Walls and the fan-like training given to plants growing on them afford such glorious opportunities for ripening the wood, that it can be left longer than in any other method of garden treatment, and we do not usually find ourselves in the difficulty with which we are faced in dealing with Roses on pillars.

All this may perhaps appear somewhat complicated to the novice in pruning, but let him have an eye for the development of his plant and carefully consider the growth of the previous year, and ordinary common sense will carry him far. "New wood" should be his watchword, new wood to give him flowers, and new wood to renew the life of the Rose, and, notwithstanding much that has been written in a contrary sense, I do not think he will go far wrong if he adds "when in doubt prune hard." *White Rose.*

NURSERY NOTES.

PRIMULAS AT READING.

Messrs. Sutton & Sons' collections of Chinese Primulas have been delightfully attractive during the past few weeks. The plants cultivated expressly for seed-saving purposes number 15,000; and many more plants are grown for the purposes of cross breeding, a work which the firm continues with marked success from year to year. As on previous occasions, we were impressed during a recent visit with the uniformity of foliage and flower of each of the many pure-bred varieties: a sure proof of careful breeding. It might well be supposed that in compactness of habit, at any rate, the seed grower has achieved

all he ever wished to obtain in the present forms of *Primula sinensis*. Nevertheless, of *Primula sinensis* it may be said with truth that "Ever out of it comes something new," and it is not unlikely that the novelties of the immediate future will rival those of the present. However that may be, it is impossible to over-appreciate the excellence observed in regard to colour purity, whilst the brilliance of the red and crimson varieties exceeds anything that this species might have been expected to furnish. The varieties Crimson King and Brilliant King, as they are grown by Messrs. Sutton, and grouped together in great batches of hundreds, produce a remarkably imposing impression of brilliancy of colour. The finer blue varieties, including Reading Blue and The Czar, appear best in a moderate light, rather than in the brilliant sunlight which appears to enhance the crimson flowers. Coral Pink and other varieties of pink or orange-pink shades are better when grown in a higher temperature than that given to most of the other varieties; hence it is well to place them at the warmer end of the house. Unless this extra stimulus is given to growth, the tardy development of the flowers prevents the perfect production of these charming shades; especially is this the case if the lower temperature is accompanied by more atmospheric moisture than is necessary. A freely-circulating atmosphere in conjunction with suitable temperatures are the main conditions for the successful cultivation of Primulas.

In the giant types we see the ordinary florists' flowers characterised by great heads of blossom and extreme vigour, and the qualities which distinguish the giants are not the results of cultivation, for they preserve the giant characteristics, even if their roots are confined within the small space of a 3-inch pot. In the "magnifica" strain one cannot help but admire the embroidery of the perfectly formed flowers. In each section the range of colour is wonderful. Pink Royal White, Giant White, Crimson, Salmon pink, or Terra Cotta and Giant alba magnifica all belong to the true giant race. The improved Giant Crimson, as seen at Reading, is a gorgeous piece of colour; its huge flower trusses and brilliantly-coloured flowers make it unique.

The greatest break in the modern *Primula* doubtless occurred with the advent of "The Duchess" some eight or nine years ago, and it is to-day one of the most popular and attractive varieties of its race. The flower has a white ground, and is rendered conspicuous by a large rosy zone surrounding a yellow eye. Quite a race of Duchess hybrids has been developed since the advent of the first plant, and the colours vary from blush-white to crimson, yet all are characterised by the zone of colour near the centre of the flower. Many of the hybrids from the Duchess are most inconstant, and they are offered as hybrids owing to this inconstancy. The "Stellata" group has numerous admirers, for its usefulness is greater perhaps than that of any other section. It may not be judged from the same point of view as the florist's *Primula*, but the Star *Primulas* are welcome companions to the more highly-developed dwarfier strains. Pyramidal in habit, free and profuse in flowering, the specimens are valuable in a cut state, and are capable of maintaining their freshness during long journeys. In usefulness they excel all other *Primulas*. The newer shades in this section and the different combinations of foliage and flower add increased interest to the group. Dark Blue Star and Ruby Star may be said to have almost approached in depth of colour the well-known varieties The Czar and Crimson King. One of the latest modifications in the *Primula* flower at Reading is the disappearance of the "eye," for flowers without this characteristic have been exhibited recently. They failed to find very much appreciation, but, at the same time, it is the business of the plant-breeder to be ever on the watch for anything that is a deviation from the normal and to seek by all the methods known to him to make use of new variation for the purpose of selecting characteristics that will eventually be accorded

public appreciation. This is appreciated nowhere more than in the Reading establishment, and for this reason and because also of the skill in cultivation displayed there, the *Primula* houses of Messrs. Sutton provide one of the most beautiful sights imaginable.

HOW WE MADE A MORAINÉ.

AFTER reading Mr. Reginald Farrer's description of a moraine and the plants to grow in it, we resolved last March to make one on a small scale at Holland House. Having selected a site at the end of a vine border, the site being 24 feet by 5 feet, we dug out all the soil to the depth of 2 feet, then put 6 inches of clinkers over the bottom, then 6 inches of half-rotted leaves, and a layer of broken sand-stones. On the top of the leaves was spread 6 inches of good fresh loam, leaving a smooth surface, over which was placed a layer 4 inches deep, of crushed granite, such as is used for surfacing paths. A slight slope was allowed towards a path that runs parallel with the moraine. Embedded in the granite are placed small tufa stones, varying in height from a few inches to 1 foot, among and on which are planted the Alpines. Along the front next the walk the moraine is bounded by a low wall of rough stones 9 inches high.

Between the stones we planted a variety of mossy Saxifrages, which have quite overgrown the wall; the varieties are *S. hibernica*, *S. muscoides*, *S. Warei*, *S. "Guildford Seedling"*, *S. decipiens*, *S. caespitosa*, *S. Rhei*, *S. muscoides*, *S. gemeliana*, *S. pedatifolia*, *S. hypnoides*, and *S. Stamfieldi*. These all grew so freely they had to be kept pinched to keep them from overgrowing one another. The encrusted or silver Saxifrages planted among the boulders have spread splendidly, covering some of the small stones. The sorts are *S. Aizoon*, *S. minima*, *S. stenoglossa*, *S. sabina*, *S. Portae*, *S. Engleri*, *S. adonensis*, *S. Cotyledon altissima*, *S. cultrata*, *S. gaudina*, *S. Macnabiana*, and *S. semipervoides*.

Of Campanulas the following were planted, and are all doing well, *C. barbata*, *C. Allionii*, *C. pusilla*, *C. caespitosa*, *C. phytameoides*, *C. garganica excisa*, and *C. Zoysii*. *Shortia galacifolia* and *Galax aphylla* revel in the granite as does *Achillea rupestris*, which flowered profusely. We tried a few varieties of *Draba*, but find that they are too weedy for this situation, so they will be removed, but *Erythraea diffusa* is a gem, and does far better on the granite than on the rockery. *Edraianthus serpyllifolius* has made a fine clump, and gave us a good show of flower. *Oxalis cuneaphylla* is a slow grower, but seems to like its place by the side of a boulder, and is making progress. It produced a few flowers early in summer. The *Dianthus*es, although small when planted, have grown finely, and promise a good display in this coming season; the sorts planted are *D. alpinus*, *D. glacialis*, *D. Freynii*, and *D. neglectus*.

We ought to have known better than to plant *Mentha Requienii*, which is too aggressive for a small moraine, and had to be continually pinched in, now it has succumbed, and we do not regret it. *Sedum brevifolium*, perched in the crevice of a boulder, looks quite happy, while *S. spatulifolia* has quite taken possession of a boulder all to itself, and *Sedum Anacamseros* likes to ramble over the granite floor. *Thymus alpina*, *T. micans*, *T. Azarica*, and *T. Serpyllum atro-coccinea* take to the moraine quite naturally, and will prove all too rampant for their situation.

These are a few of the plants we have tried, and the result has been so satisfactory that we are making a much larger moraine on a sunny site in the rockery, which will be constructed on the same lines as the smaller one. I may say that beyond watering the plants at the time of planting they received no further artificial waterings during the season. *Charles Dixon, Holland House Gardens, Kensington.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM ROSEFIELDIENSE

THE illustration in fig. 75 represents an inflorescence of the handsome *Odontoglossum Rosefieldiense* (*O. Harryanum* × *O. Lambeanianum*) shown by the raiser, de B. Crawshay, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), on January 17, when the hybrid was given an Award of Merit by the Orchid Committee of the Royal Horticultural Society. Mr. Crawshay has raised many hybrid *Odontoglossums*, but *O. Rosefieldiense* is probably the most important, it being excellent at all points. The flower is white, slightly tinged with pink on the sepals and petals, the blotching being

When potting, place the bulb so that the base of the young growth is at least an inch below the finished surface. By doing this, the bulb is not only made firm, but when the new roots are produced the risk of them being eaten off is not so great, and they take more readily to the soil. During the potting, keep turning the compost, as the corks have a tendency to work down to the bottom, and in the mixing of plenty of corks in your potting soil lies one of the secrets of growing *Calanthes* well.

The plants like a potting medium which can be well watered, and one in which the water drains freely. This condition is brought about by the broken corks. After potting, I find it advantageous to place the plants for about three

regard to shading, as the ever-increasing foliage is tender and very easily scorched. Nothing looks worse than foliage disfigured in this way. When the pots are full of roots, which will be probably about the end of August or the beginning of September, a start can be made with feeding. Weak liquid manure may be alternated with clear water for about 10 days, after which liquid manure may be given at every watering. To obtain stout bulbs and flower-spikes, use first a good open compost which develops a healthy root action, and follow with liberal supplies of manure water. With the exception of a few applications of soot water, after once commencing the liquid manure, I water solely with it until the flowers are opening,

reddish-claret of varying shades, and showing a crimson tint when viewed in a clear light. It is one of those beautiful productions which cheer the raiser and compensate for the frequent disappointments which inevitably arise in the interesting occupation of cross-breeding.

CULTURE OF CALANTHES

ABOUT the end of February the pseudo-bulbs which have had their period of rest begin to push new shoots, and when these are about an inch long they should be potted. Much has been said and written on the subject of composts for *Calanthes*, and most growers have their own pet composition, which suits their own plants. The compost I have found to produce the largest pseudo-bulbs and the finest flower spikes is the following:—Fibrous, yellow loam two parts, *Osmunda* fibre one part, chopped *Sphagnum*-moss one part, a good quantity of broken corks, and a sprinkling of charcoal and silver sand. These ingredients should be mixed very thoroughly so that the compost is of the same character throughout.

After getting the compost mixed, place it in a warm house to get tempered, and it will then be ready for use. For the potting, only clean pots and corks should be used. Let the pseudo-bulbs be graded, and each of the largest bulbs may require a pot with a diameter of 8 inches. The next size will require 7-inch pots, the next 6-inch pot, and the smaller bulbs may be placed three together in a 6-inch or 7-inch pot according to size.

weeks when they have tall exposure to the light, but after that they should be shaded carefully from all direct sunlight.

Syringe frequently between the plants and pots, just keeping the compost moist, so that the *Sphagnum*-moss will have a chance to grow. Increase the amount of water as the plants make more roots, and still use the syringe among the plants. As the summer increases, be more careful with

[Photograph by L. H. de Bari Crawshay.]
 FIG. 73.—ODONTOGLOSSUM ROSEFIELDIENSE.

when clear water is used exclusively. As the foliage ripens, less nourishment is required, and when the leaves have all fallen, just enough water to keep the bulbs plump should be given.

When in flower, *Calanthes* may be placed in a cooler structure. After flowering, store the pseudo-bulbs in a cool, dry place, allowing them to remain in their pots. Insect pests are not very troublesome, brown and white scale being the most common, and these may be destroyed by sponging the leaves with an approved insecticide. The members of the *C. vestita* group of *Calanthes* are most useful, and of these *C. Veitchii* is the favourite. *A. W. Proudlock.*

NOTICES OF BOOKS.

ORCHIDS FOR EVERYONE.*

THE object of this work, as is explained in an introductory chapter, is to extend the popularity of Orchids among that ever-increasing class of business people which has a love for plants and flowers, and finds in their study and culture a delightful recreation and an absorbing hobby. The book is divided into two parts, described as "The Most Useful Orchids" and "Orchids of Lesser Value," the former naturally comprising the bulk of the work. In it are enumerated the best kinds with which to commence Orchid culture, due regard being paid to beauty, interest, ease of culture, and cost.

Preceding this section, however, we find a chapter devoted to "Hybridisation: Seed and Seedlings," including a brief history of the question, with instructions as to the work of pollination, recording the crosses, raising the seedlings, and bringing them up to the flowering stage. Details as to potting, watering, temperature, and other cultural matters are given, which should enable anyone having the necessary appliances to embark in this fascinating branch of Orchid culture with a fair amount of confidence.

Coming to the systematic part of the work, we find an alphabetical enumeration of the most popular genera, with instructions as to their culture, brief descriptions of the most useful species and hybrids, and in some cases a list of "other species and hybrids," which seem to have wandered away from that part of the book devoted to "Orchids of Lesser Value," showing how difficult it is to follow a classification of this kind. Such genera as *Cattleya*, *Cypripedium*, *Dendrobium*, and *Odontoglossum* are necessarily treated in considerable detail.

Under "Orchids of Lesser Value," we find a short account of numerous genera which are not so generally grown, though a few species are included which, under another arrangement, might have been placed among the more popular kinds. On the other hand, it might have been much extended by the inclusion of the less important kinds included in the earlier part of the work. The fact is that no genus appears in both parts, which increases the difficulty of the system of classification adopted. We next find a chapter devoted to "Hardy Orchids," and a "Calendar of Reminders," including details requiring attention during the different months of the year.

The illustrations are the feature of the work. There are 53 in colour and 43 in black and white, the former being colour photographs and the latter half tone blocks. They are, however, scattered indiscriminately through the book, without reference in the text to the figures or references under the figures to the corresponding text. True, there is an enumeration of the figures at the commencement, but it is not alphabetical, and there is an alphabetical index at the end, but it gives no indication of what is figured. Altogether, the reader who wishes to find his way among the figures soon becomes rather distracted.

The colour photographs are in many cases very beautiful, and the colouring fairly accurate,

though there are exceptions, and, particularly among the greens, examples could be pointed out, as, for instance, in the plate of *Vanda cœrulea*, that are far from satisfactory. The plates of *Calanthe Veitchii* and its white variety, *Disa grandiflora*, and *Dendrobium thysisiflorum* are very successful. In the plate of *Odontioda Charlesworthii* and its parent, the reds are very far from correct. A group of *Laelio-Cattleyas* in Messrs. Charlesworth's nursery, however, illustrates very well the possibilities of the process.

A word in conclusion as to the vexed question of nomenclature. Mr Curtis has adopted the system of a rational and uniform system of nomenclature for hybrids, which the writer has long advocated, and has carried it out systematically, and the names *Cattleya Murrayi* and *Brasso Cattleya Veitchii* may be cited as illustrations. The author, artist, and publishers may be congratulated upon the production of a handsome volume. *R. A. Rolfe.*

VELTHEIMIA VIRIDIFOLIA.

THOUGH the flowers of *Veltheimia viridifolia* are not of brilliant colouring, the plant is a good garden subject, as it blooms with freedom every

FIG. 74.—VELTHEIMIA VIRIDIFOLIA.

year, no matter what treatment has been afforded it. The plant shown in fig. 74 has probably not been potted for six or more years, although it could not well be surpassed in health and freedom of flowering. The flowers are of a reddish pink colour, and are produced on scapes about 2 feet high. The light-green foliage is also ornamental, whilst the membranous capsules and black seeds are both attractive. The plant is a native of South Africa, and is allied to *Lachenalia*. There are three other species of *Veltheimia*, but only one other is, I believe, in cultivation. This is *V. glauca*, which is distinct from *V. viridifolia* in its glaucous and longer foliage and smaller, inferior flower. I have two forms of the plant, one much more glaucous than the other. Little need be said about the cultivation of *V. viridifolia*. It should be potted truly in good sandy loam, and, like many other fleshy-rooted bulbs, it does much better if allowed to remain from year to year without disturbance. *Veltheimia viridifolia* is a well known plant in botanic gardens, but is rare in cultivation, and yet it certainly merits a place in any garden. The plant illustrated in fig. 74 was grown in the Botanic Garden, Cambridge. *R. Irwin Lynch.*

THE ALPINE GARDEN.

HUTCHINSIA ALPINA.

A PRETTY little plant with a somewhat indifferent reputation is *Hutchinsia alpina*. One grower tells us that it does not thrive with him, that it never makes a plant of any size, and that it will dwindle away and become one of the "lost ones of the garden." Another speaks in a different vein, and pictures a plant which threatens to crowd out its choicer neighbours, and become a perfect "old man of the sea" in the rock garden. Such are two diverse statements.

The behaviour of the plant is very much a matter of treatment. If the *Hutchinsia* is given a very dry place, where it is parched and sun-dried in summer, it will probably bear out the first statement, but if it is planted in close proximity to some exquisite little silvery Saxifrage, as, say, *S. cochlearis*, and allowed to spread in a mass, encouraged by plenty of moisture at the roots and the nourishment of a good soil, it will be little wonder if you find that it has encroached upon the quarters of the Saxifrage, or other gem of the Alpines, which may be close by. But no one who knows the ways of such plants will ever put choice, slow-growing subjects within the reach of a strong grower. A little care in surrounding the *Hutchinsia* with stones partly sunk and of some size will keep it in bounds.

The *Hutchinsia* will then make a cushion of charmingly cut foliage of a delicious dark green, which, in its season, is adorned with the little heads of white flowers. Despite it though some may, because it is a "crucifer," and therefore of a common race, the *Hutchinsia* is not worthy of ignominy. Plant it well up, but not in a place too dry, give it a chance to spread, and this North American flower will not prove itself unworthy of its position on the rockery in a climate not too dry. *S. Arnott.*

FLORISTS' FLOWERS.

THE AURICULA.

WITH the advent of March the Auricula starts into vigorous growth, and from that date, until the trusses of bloom are fully developed, at about the end of April, interest in the flowers increases day by day. I have been a cultivator of Auriculas for half a century, and my interest in them has never flagged. When I first began to take an interest in the plants they were grown principally by men who were shy to express any opinion on the culture of their plants. I well remember visiting the Auricula growers in Lancashire, principally in the neighbourhood of Manchester, nearly 40 years ago, and it was easy to see that their methods were quite contrary to good floricultural practice. The plants were in some instances overpotted, and in others coddled. They were shut up in frames that were covered with double mats or thick sheeting at night to keep out the fresh air. I have some 15,000 Auriculas in frames, and in a house specially built for them, but neither the frames nor the house has had any covering during the past winter. The ventilators have been open both night and day in the house, and the lights of the frames have been tilted. But now that the trusses of blooms are developing, it is well that they should not be frozen. There are two rows of hot-water pipes in the house, so that the temperature may be maintained above the freezing point. The plants were all surface dressed in February; a few of them, where a worm was suspected in the soil, were turned out of the pots to have their roots examined, or where the Auricula aphid was thought to be present. The best way to get rid of the aphid (*Trama auriculae*) is to apply methylated spirits, which causes instantaneous death to the pest. As the growth of the plants will now advance rapidly, it is well to give careful

* By C. H. Curtis, with coloured illustrations by T. Ernest Waltham. (London: J. M. Dent & Sons, Ltd.) Price 41 1s.

attention to watering, as dryness at the roots is very injurious to the plants, and checks the development of the inflorescences. Amateurs often enquire what is the difference between a show Auricula and an Alpine Auricula. They are both Alpine plants, but for garden purposes the show or edged Auriculas are the florists' forms of *Primula Auricula*, and this type has been grown and exhibited at Auricula shows for 150 years. There are green, grey, and white-edged types, as well as selfs. The leaves are in some instances covered heavily with a white farina, and foliage of this character is exceedingly beautiful, especially in March. The Alpine Auricula is now as freely exhibited at exhibitions as the "show" Auricula. It is derived from *Primula pubescens*; the leaves are green and quite free from farina. The Alpine Auricula makes an excellent rock-garden plant. The flowers are also not mealy. This type of Auricula has been greatly improved in recent years, and the florists now recognise two classes of Alpine Auriculas. The white-centred varieties have the margins shaded a purplish, violet, or lilac tint, with shades of blue occasionally. The yellow-centred varieties have the margin shaded also, but the colours are maroon red, crimson, and apricot-tinted. Some gardeners and amateurs are of the opinion that the Auricula is a plant very difficult to manage, but I never found this true. The use of a too rich soil has been the rock on which many have foundered. Keeping the plants closely shut up in frames is another evil. Let the potting soil be such as is used for Fuchsias, Pelargoniums, Calceolarias, or other soft-wooded plants; drain the pots well; pot firmly and never overpot. Pots of 4 or 5 inches diameter are large enough for the strongest plants. Allow the plants plenty of fresh air both night and day, and it is well to keep them from frost from the first of March until the flowering period is over. *Jas. Douglas.*

THE MARKET FRUIT GARDEN.

LIME-SULPHUR FOR SPRAYING.

At the present time the great subject of discussion among American fruit-growers is the policy of adopting lime-sulphur as a summer wash for fruit trees, in place of Bordeaux mixture, which often causes scorching and defoliation. The former has already come into extensive use as a winter wash; but it is only during the last three seasons that it has been tried in diluted form on the foliage of Apples and Peaches. For some years I have used it in winter or early in the spring as a protection of the buds of Plums and Gooseberries against birds when an attack has begun, and last year it was applied to Apples and Plums just before the buds burst, as a substitute for any other winter wash, apart from any consideration as to bird-eating birds. It was used at that time, as it has just been used again, with the object of killing any mother-queen aphides that might be on the trees, as well as for the usual purposes of a caustic winter wash, such as the possibly partial destruction of the eggs of aphides and Apple-suckers, and the cleansing of trunks and branches from moss and lichen. It is possible also that the fungicidal action of this wash may have some effect where scab or brown rot has attacked the wood of trees. For all these purposes an artificially-boiled solution is much more efficacious than the self-boiled mixture which is a chemical solution only to a small extent. In the United States many proprietary preparations of the kind are in the market; but in this country there were none until last year, when Messrs. Voss and Co. prepared one for my use. For application while trees are dormant, this solution is diluted, so that it contains about 10 lbs. of sulphur in 50 gallons of wash. So diluted, it is at least as strong as a self-boiled mixture containing 20 lbs. of sulphur to 50 gallons.

For the last three years, Professor Scott, of the United States Department of Agriculture,

has been experimenting with the self-boiled mixture on Peaches and Apples in foliage, and with commercial and home-made preparations artificially boiled, in addition, on Apples. The self-boiled mixture, made with 8 lbs. lime and 8 lbs. flower of sulphur to 50 American gallons of water (equal to fully 9½ lbs. to 50 imperial gallons) proved an effective preventive of Peach scab and to Peach brown-rot also, except when the disease obtained entry through the wounds made by the curculio, in which case lead arsenate had to be added. At the strength named, this self-boiled wash did no harm to the foliage of either Peaches or Apples; but it proved only a partial remedy for Apple scab. The artificially-boiled solution was much more effective against Apple scab than the self-boiled, and about equally so with Bordeaux mixture, whilst it produced less scorching to the foliage than the latter, if sufficiently diluted. This appeared to be especially the case when lead arsenate was mixed with it, as this substance appears to neutralise the scorching tendency. Professor Scott's results in 1910 are not yet published, but his experience up to the end of 1909 led him to recommend a trial on Apples of commercial or home-made lime-sulphur artificially boiled, so diluted as to contain not more than 4 lbs. of sulphur to 50 American gallons of water, equal to 4½ lbs. to 50 imperial gallons, with 2 lbs. of lead arsenate. In other words, Professor Scott recommends the dilution of 1½ gallons of a commercially-boiled solution, testing 32° on the Beaumé hydrometer, with 50 gallons of water. Used in that strength, no scorching, or none worth notice, took place.

Now, if self-boiled lime sulphur will not sufficiently control scab, its use alone on foliage may be dismissed. But, with the addition of 5 lbs. of iron sulphate (copperas) or 2 lbs. of copper sulphate to 50 gallons, the self-boiled mixture was found by Professor Waite, of the American Department of Agriculture, to be a highly promising preparation. The iron mixture is reported to have benefited the foliage and buds of the trees sprayed with it, and the only objection to it was that it appeared to delay the ripening of the fruit, while imparting an extra green colour to it.

Experiments carried out by Mr. E. S. Salmon, of Wye College, are reported by him in the *Journal of the Board of Agriculture* for February, in which, or in a leaflet issued at Wye, all instructions for preparing the washes are to be found. But readers must be warned, as Mr. Salmon recognises, against any trial of lime sulphur on foliage, except on a small experimental scale, until further experience has indicated whether it can be safely used at a strength sufficient to render it valuable as a fungicide. A trial on a few trees of a variety susceptible to damage, like Cox's Orange Pippin, will show in a few days whether it will be safe to operate on a more extensive scale. *A Southern Grower.*

MARKET APPLES.

In entering the names of the Apples grown by us in our *Stock Book*, I was surprised to see that the varieties were so few. The last three years we have planted several acres with Apples, and these have been sorts that have proved the best for the Midland markets.

Taking eight of the finest cropping varieties in alphabetical order these are:—Bramley's Seedling, good either on the Crab or Paradise Stock; Emmeth or Early Victoria, a local variety, of which we have a large number of trees; Grenadier, a tree of good, sound habits, producing fine market fruits by the end of September and October; Lord Derby, good both on the Crab and Paradise Stocks—we receive the highest price for this bulky Apple, and we are extending our plantings of it. Lord Grosvenor, which follows Emmeth for gathering, is a profitable variety, but the trees are subject to canker; Lane's Prince Albert, a sure fruiter, and too prolific in the case of the young trees; to encourage the growth we cut through a number of the fruit-buds when pruning or thinning the growths; Royal Jubilee,

a certain cropper with us, and a healthy tree; Worcester Pearmain, which we plant between Bramley's Seedling, and cut out the trees later.

FARMYARD MANURE FOR RED CURRANTS.

Market gardeners know well that only large, bright bunches of Currants are required by the market buyers. For the production of fine bunches, nothing equals a good layer of farmyard manure spread over the roots as late as possible in March, and then lightly covered with soil. The pruning of the bushes has been delayed, because birds destroy many of the buds if the work is done early. The wood of the Red Currant bushes cannot be too strong for successful cropping, and the farmyard manure will cause the growths to become extra vigorous. *Stephen Castle, Walpole St. Andrews.*

CULTURAL MEMORANDA.

FLAVOUR OF MELONS.

Of late years the English grown Melon has been in much greater demand than formerly. This is no doubt due to the many different ways in which it is served at table as a sweet. For this purpose, the scarlet or pink flesh kinds are preferred on account of the colour, which is more attractive than the pale flesh kinds. As a dessert fruit in the raw state, flavour is, of course, the most essential feature, and many people prefer the green or scarlet flesh fruits as being superior to those having pale flesh. This is a matter of opinion, and I think that equally good flavour is to be found in both sections. In experimenting with the crossing of Melons, I have noticed that the fruits which have been cross fertilised are invariably of excellent flavour. This would suggest that the constant raising of new varieties is necessary in order to keep up a high standard of excellence in regard to flavour. It is well known that the flavour of Melons deteriorates in time, more so than many other kinds of fruit. This being so, growers of Melons should not place too much reliance on old varieties which have been formerly held in high estimation. Probably no variety has stood the test of time so well as Hero of Lockinge, but it is difficult to recognise in the fruits which are shown now as Hero of Lockinge any resemblance to that variety of 20 years ago. This would seem to indicate that a new blood has been infused into the old variety.

Of course, culture has a great deal to do with producing flavour, and any checks in the growth of the plants, such as would be caused by over dryness at the roots, or very low temperatures when the fruits are swelling, are detrimental. The Melon needs a rich rooting medium, but it is possible to have it excessively rich, and stimulant should not be applied to the plants till the fruits are swelling, or it may cause canker. The plants must, however, be fed liberally when the fruits are swelling. Another important point is to know just when the fruit is in proper condition to send to table. They should be cut before they are quite ripe, and placed in the fruit-room for a day or two before being used. They will keep in good condition for four or five days in a cool room if taken from the plants at the proper time. *H., Frognour.*

SCOTLAND.

GIFT OF A PUBLIC PARK TO LOCKERBIE.

At a special meeting of the Lockerbie Town Council on March 7, a letter was read from Sir Robert W. Buchanan Jardine, Bart., of Castle-milk, offering to hand over to the burgh about five acres of land, known as the Volunteer Field, to be used as a public park, as a memorial of the late King Edward. The land is situated at Town-head, and is very suitable for the purpose of a public park. It was unanimously agreed to accept the gift, and to convey to Sir Robert Jardine the thanks of the council.

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALI VANDER, Orchid Grower to Lt.-Col. Sir G. L. Herford, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

DECIDUOUS CALANTHES.—Those plants which bloomed early will now need attention, as the potting should be carried out as soon as the young growths are about 2 inches high. On no account should the plants ever be allowed to remain a second year in the same soil, for, however fresh it may now appear, it will be in a condition unsuitable for them long before they finish their season's growth. Large or small pots may be employed, according to the requirements of the plants. Strong pseudo-bulbs should be potted up separately in 5-inch and 6-inch pots, this being the best way of utilising Calanthes for decorative purposes in a growing state. When a mass of flower-spikes is desired, the smaller bulbs may be grown several together in 7-inch or 8-inch pots. The pots should be quite clean, and each must be provided with good drainage. Mere quantity of drainage material is not the only point to look after, as a pot containing one-quarter of drainage at the bottom properly placed is more effectual than double the quantity carelessly arranged. About an inch deep of chain cloaks is usually sufficient, covering these over with a thin layer of turf or dry Sphagnum-moss. Various kinds of potting material for these plants are recommended by different cultivators, both with and without the addition of dry, shady cow manure. A compost giving very satisfactory results is one largely composed of good fibrous loam; two parts of this to one of partly-decayed Oak leaves or chopped Sphagnum-moss, with a free addition of sharp silver sand and crushed charcoal to render the whole porous. When the loam is of a heavy character, I do not favour the practice of using manure in the compost, as an excess of it produces disastrous results. If given when the pots are full of manure is beneficial, and it can be supplied as a surface dressing or in a liquid state, the latter being preferable. As regards potting, the soil should be neither too wet nor too dry, and it should be thoroughly warmed before using. It will be found better to shorten the old, dead roots at the base of the bulbs to within an inch than to remove them, as by pressing the rooting material firmly round the shortened roots the bulbs are kept in their place until the new roots get firm hold of the soil. If the base of the pseudo-bulb is kept about an inch under the rim of the pot, a top-dressing may be given with advantage later on. A moist, warm atmosphere is necessary during the time the plants are making their growth. The temperatures should range from 65° to 70° by night, with a rise of 15° or 20° by day, accompanied with a light shade during the hottest part of the day. No water whatever should be given for several weeks after potting beyond merely keeping the surface soil moist to encourage root action. It is during the early stages of growth that discretion is needed, for if over-watered at first the soil becomes sated, and unhealthy growth is the result. In addition to the new growths produced from the base of the bulb, they sometimes push one or two from the upper portion. If a sufficient stock of Calanthes exist, with no necessity for further increase, these upper breaks should be rubbed off as they are formed, by which means the principal growths from the base will develop into larger bulbs. Calanthes should be given a place near to the glass.

THE FLOWER GARDEN.

By R. F. BROMFISTON, Gardener to the Earl of Hunsington, K.F., Tynninghame, East Lothian.

SEED SOWING.—Provided the soil is in a proper condition, the seeds of many kinds of hardy perennial plants may be sown during the next week. Seeds of some subjects lie in the ground for 12 months, or even longer, before germinating: Eremurus, Eryngium, and Aconitum being examples. But the majority are not long in appearing above ground. Polyanthus and Primrose seeds sown at once will produce plants

that will flower the following spring, and some may bloom in the autumn of the present year. Bulbous subjects such as English Bises, Brodiaeas, Alliums, Fritillarias, and Galtonias may be raised readily from seeds. In favoured districts hardy annuals may also be sown, but in the north and other colder parts it is preferable to delay the work till April. Small seeded species such as those of Linaria and Lobel's Catchfly (*Silene Armeria*), a delightful old plant, need only to be raked in and the surface soil smoothed with a spade, but seeds as large as those of *Saponaria calabrica* should be buried half-an-inch, and those the size of Sweet Peas 3 inches below the surface. Among the desirable annuals are *Alyssum minimum*, useful for carpeting and edging; *Calendulas*, Orange King, Lemon Queen and Meteor; *Chrysanthemums* in variety; *Centaurea Cyanus*, the type with blue flowers is best for effect; *Clarkia elegans*, the double salmon variety being of great value; *Convolvulus minor*, *Crocopsis*, *Dianthus chinensis*, *Salmon Queen* and *Scarlet Queen*; *Godetias Shamini*, and Sutton's Dwarf Pink; *Lavatera rosea splendens*, *Lupinus Hartwegii*, with azure-blue flowers; *Linaria* in many sorts; *Nigella Miss Jekyll*; *Cardinal* and *Salmon Pink Poppies*, *Salvia Hornum* and the pink variety; *Saponarias calabrica* and *alba*; *Senecio elegans* of the dwarf varieties; *Tropeolum peregrinum*, *Brachycome ibervilleana*, both blue and white flowered; *Sweet Sultan* and *Xeranthemum super-bissimum*, a beautiful old plant; whilst for transplanting, French and African Marigolds, Single China Asters, Cockscombs, *Colosia*, *Diascia Barbera*, *Dimorphotheca aurantiaca*, *Dwarf Cosmos*, *Matricaria Golden Ball*, and *Bilox Drummondii* are to be recommended. Seeds of *Rhodantha*, Ten-week Stocks, Sunflowers, *Tagetes signata*, and *Zinnias* should be sown in boxes of light soil and germinated under glass. All the above, in one or other of their many varieties, are well worth growing, but in most gardens it is better not to grow them all every year, but rather a selection of sorts one year and another and different selection the next.

ROSES. Continue the pruning of Dwarf Roses. In no case should old wood that has been injured by frost be allowed to remain, as it only weakens the plant, whereas, if cut close to the base, strong shoots are produced from near the ground. Worn-out standards may also be rejuvenated by hard pruning. After the plants are pruned, the surface soil should be forked neatly; and if it is considered necessary some decayed manure worked in. Roses such as *alpina* and *rubrifolia*, which produce coloured shoots, should have some of the growths cut hard back to induce the formation of long and vigorous branches. The variety *Reine Olga de Wurtemberg* is worth growing for its bright green shoots alone, but hard pruning is essential with this Rose.

SCHIZOSTYLIS COCCINEA. To obtain the best results with this beautiful subject the plants need to be highly cultivated. The present is a suitable time to hit the plants. Apply a thick dressing of cow manure and dig it into the soil, when, after selecting the strongest growths, they may be replanted at once.

FRUITS UNDER GLASS.

By L. BECKETT, Gardener to the Hon. Vicary Gibbs, Aldenham House, Hertfordshire.

MELONS.—There has been a fair amount of sunshine during the past month, and this has been favourable to the growth of Melons, for it has been possible to admit a little air to the houses. These conditions should have the effect of preventing attacks of canker on the stem of the plants, and the prospects therefore are good for crops of highly-flavoured fruits. Whilst the plants are in flower they will need rather more fresh air admitted whenever the weather will permit, but do not allow this to reduce the heat too greatly. The use of the syringe must be discontinued until the fruits are set. Lightly stir the surface of the soil of the bed, and damp the walls and paths during the period of setting the flowers, otherwise it is probable that the plants will become infested with Red Spider. As soon as a sufficient number of fruits is formed, let the foliage be given a thorough and vigorous syringing with clear water, and continue to keep the house well charged with moisture afterwards.

The trallis should be well clothed with healthy foliage, not too thickly placed. Remove laterals as they appear, stopping them at the first leaf. During the period when the fruits are swelling, the plants will need frequent applications of manure; liquid manure from the farmyard, properly diluted, and soft water make very good stimulants, whilst a sprinkling of some artificial manure on the surface soil, well watering it in afterwards, will afford a change of food. Let a further sowing be made for supplying successional plants.

TOMATOS.—The earliest batch of plants raised from seeds sown last November should now be ready for the final potting. At this season of the year the pots should not be excessively large; those of 9 inches diameter will be suitable. Pot firmly, using a compost of principally loam, to which has been added some leaf-soil and bonemeal. In potting, place the ball of soil as low in the pots as possible, and just cover the roots with soil. This will leave space for top-dressings to be applied as the growth matures and the fruits swell. The plants will require to be placed in a warm house, where they can obtain plenty of fresh air. Water must be applied with great care for some time after the plants have been potted. On fine days, they may be syringed lightly and the spaces between the pots damped. No stimulants of any kind should be given the plants until the first truss of fruit is set. If ripe Tomatos are required at an early date, their ripening may be hastened considerably by stopping the plants after they have set about three or four trusses of fruits. Keep the side growths removed and, if necessary, to admit the light to the fruits, remove some of the foliage by shortening the leaves. Special cultural attention might be given in the case of the yellow dessert varieties, such as Golden Nugget and Sunbeam.

PINEAPPLES.—The houses in which Pineapples are growing should be kept warm, allowing a night temperature of 70°, unless the weather is very cold. When the plants are in flower, a drier atmosphere must be maintained. Remove the "gills" from the fruit stems, and the suckers from the base of the plant. Support the stem by sticks placed in the beds. When the flowering period is over, the house may be damped freely again, and frequent syringings given, using tepid water. Plants that were potted for successional fruiting are rooting freely, but care must still be exercised in applying water to the soil. Fruiting plants will be benefited by occasional applications of diluted manure water.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gammersbury House, Acton, Middlesex.

IXORA. As stove decorative plants, *Ixoras* stand in the front rank. It is quite possible to have them in flower from May until November, the earliest plants to flower being those that make a late summer growth. *I. coccinea* is one of the best to grow for early flowering; but *I. javanica floribunda* is valuable for the same purpose. Indeed, this latter variety will flower twice in one season, or at least three times in two seasons. *I. macrothyrsa*, although of rather straggling habit, is a first-class variety, and has large flowering trusses. *I. salicifolia* is equally attractive, if not so showy; but, for freedom of flowering, the variety known as *Prince of Orange* is one of the very best; whilst *I. Fraseri* is a very showy plant. With the possible exception of *I. salicifolia*, all the sorts I have mentioned are useful for use as cut flowers in specimen vases, and the plants are decorative as vase plants in the summer-time. The present is a good time to prune, clean, and repot those which need repotting and are intended for flowering late in the summer. There is nothing to be gained by starting the plants too early into growth, it being better to wait until the days are a little longer and there is more sunshine. If the stock needs to be increased, cuttings may be taken at the present time, and they will root quickly in sandy soil over a hot-bed. *I. salicifolia* is more satisfactory when grafted upon *I. coccinea* than from cuttings. After *Ixoras* have been repotted, they are benefited by being placed over bottom heat, nothing being better for this purpose than a bed of Oak and Beech leaves.

The plants are very liable to mealy bug, therefore, as soon as they have been pruned, any plants affected with the pest should be syringed with water as hot as the operator can use it. Then dress the plants with an approved insecticide, which will be more effective after the application of hot water. If remedial and preventive remedies are practised, the pest can be eradicated.

THYRSACANTHUS RUTILANS.—This stove species is very showy in the early spring months, and its growth is quite simple. It has been my practice to grow the plant as standards 4 or 5 feet in height, for in this way the long racemes of flower are seen to the best advantage. Such plants can be so arranged when in flower as to hang over the pathway of the house. Cuttings should be inserted as soon as the young growth is made after the flowering season. They should be grown on the single-stem system until the required height has been attained. Older plants will still be serviceable, and these will thrive during the summer in a cooler house. In favourable localities in the south of England I have cultivated the plants out-of-doors during the summer-time.

CROSSANDRA UNDULÆFOLIA.—This Acanthaceous plant is a choice species for the stove during the summer season, for its spikes of brilliant orange-coloured flowers are very attractive. Cuttings may now be taken for raising plants to flower late in summer, and they will afterwards be found serviceable for cultivation another year. Seed may be saved in due course, but the seed-pods must be closely watched, otherwise they will burst when fully ripe, and the seed will be scattered, as in the case of *Aphelandras*.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

LEEKS.—Seeds of the main batch of Leeks should be sown as soon as possible in drills drawn one foot apart. Musselburgh is a good variety for general use. The plants may be permanently planted at a distance of 1 foot apart in the rows as soon as they are large enough to be handled. If large Leeks are required, select such varieties as *The Lyon* and *Dobbie's International*. Young Leeks growing in pots should not be allowed to become drawn through keeping the pits too close. A temperature of 50° is suitable, and a little fresh air may be admitted both by day and night. The plants will require to be shifted to a cold pit shortly, and, after the lapse of a few days, they must be allowed plenty of fresh air, in order to have them hardy when planting time arrives, about the second week in April.

CELERY.—Seeds of the principal batch of Celery should be sown, covering them lightly with fine soil. They should be germinated in a very gentle heat. Seedlings from the earlier sowings should now be ready for pricking out into boxes or small pots. Young Celery plants should be grown on without a check, and never allowed to suffer from lack of moisture at the roots.

TURNIPS.—A sowing of Turnips may be made now without fear of the plants bolting before they are large enough for use. Sow the seeds in drills 15 inches apart, and thin the young plants to 9 inches apart in the row when they are large enough to handle. A great deal depends on this thinning being done before the plants become drawn. If birds are troublesome, a net should be stretched over the bed for a few days, and when the seedlings begin to show through the surface, frequent dustings of wood-ashes will serve to promote healthy growth. Early *Milan* and *Snowball* are good varieties for this sowing. Make frequent small sowings in order to provide an unbroken supply of young roots throughout the spring and summer months.

RHUBARB.—There should be no delay in making fresh plantations of Rhubarb. The crowns are on the move early this season, and, if lifted after growth has commenced, they will receive a check. If land was trenched and manured early in the winter, sufficient plants should be lifted and divided into small pieces for planting out in rows, which should be at least 4 feet

apart, and, in the planting of permanent beds, a distance of 5 feet may be allowed. After planting, the crowns should be just visible above the surface, and if dry weather should set in, the ground should be mulched with farmyard manure.

POTATOS.—A plantation of early Potatos may be made as soon as possible in a sheltered part of the garden, where protection from frost can be given, as Potatos are liable to be frosty until the end of May, especially in damp, low-lying districts. If the ground is wet at the time of planting, the sets should be covered with leaf-mould or manure from a spent Mushroom-bed in sufficient quantity to take the place of the soil removed from the trench. No great quantity should be planted yet, but just sufficient to meet the demand early in the season. In order to ensure success with later crops, lay out the sets in trays as advised some time ago; they will then make sturdy growths, which are not so easily broken off when planting takes place. Give abundance of air to Potatos in pits and frames, and do not allow the plants to suffer from want of water. Cold pits will still require covering at night with mats or other material, but a little ventilation should be left on heated pits at night to keep the plants from becoming drawn.

THE HARDY FRUIT GARDEN.

By W. HIBBLE MARSH, Aston Clinton Gardens, Buckinghamshire.

PLANTING STRAWBERRIES. The present time is favourable for making new plantations of Strawberries, using for the purpose late-rooted runners, which have been wintered in cold frames, or plunged to the rims of the pots in the open. When preparing the ground, it is necessary that it should be dug deeply and manured liberally. Spring-planted Strawberries ought not to be allowed to ripen fruits during the first year, for this so debilitates them that they do not bear well in the following season. The distance apart to plant depends upon the variety and the nature of the soil. Strong-growing varieties may be planted 23 or 30 inches apart, whilst those of weaker habit require but 13 or 20 inches space in the rows. The duration of Strawberry beds depends upon a variety of circumstances, some plants lasting for years, whilst others are quite exhausted after they have produced two or three crops of fruit; cultivators, nowadays, seldom allow the beds to remain for more than three years. Young plants always produce much finer fruit than older ones, and plants, after carrying an ordinary crop of fruit for three years in succession, usually show signs of deterioration. Strawberries require a liberal supply of moisture at the roots to bring the fruit to perfection, hence, if a selection can be made, a not too dry position in the garden should be set apart for their cultivation. Perhaps the most suitable site is one where the ground slopes gently towards the south, and the soil is of a loamy and slightly tenacious nature. A loamy soil, of good depth, with a gravelly subsoil, will produce perfect Strawberries; and if the surface be somewhat stony, so much the better, for it will then conserve both heat and moisture, thus effecting a saving of labour in watering the plants. A mulching of half-decayed farmyard or cow manure may be placed between the rows of plants as soon as they are planted, such a dressing will aid in keeping the soil cool during the summer season. Established beds will now need attention in the clearing away of dead and decaying foliage that may have accumulated on the plants during the past winter, and the placing of a dressing of rich material over the surface of the soil. Before applying this mulching, a slight dressing of soot may be given; this will act as a check to ground pests and as a stimulant to the growth of the Strawberries. On dry soils, a light dressing of nitrate of soda, at the rate of 1 ounce to the square yard, or about 2 lb. per rod, may be given with beneficial results. This dressing not only aids the growth of the plants, but tends to preserve the moisture of the soil. When applying this manure, great care should be used in preventing its coming into contact with the foliage of the plants, or much harm will be done. This dressing is best applied during showery weather. Autumn-fruiting Strawberries might now be planted with every prospect

of the plants carrying a crop of fruit during the forthcoming autumn. If possible, a sheltered position should be selected for these, and, if so arranged that shallow frames can be placed over them, the crop will be almost or quite assured until late in the season, and the fruit will be of the best quality.

THE FRENCH GARDEN.

By PAUL AQUATIUS.

THE HOT-BEDS.—The bulk of the Lettuces grown in the frames on hot beds has been marketed. Whenever the weather permits, the Carrots will be thinned and afterwards mulched by a layer, 1 inch deep, of finely-sifted, well-decayed manure. Five Cauliflowers are to be set amongst the Carrots in each light. If the Carrots have not grown very strong, which is often the case when the Lettuces have grown extra well, it is preferable to delay planting them for a week or so. The hot-beds intended for growing Turnips are now at liberty. The soil in the frames should be loosened and made level with the rake, preparatory to sowing seeds of Turnips "*Long Early White*" or "*Milan Flat Purple Top*." Three seeds are sown together, there being 11 rows, each with 10 sowings of 5 seeds per light. For a successional crop of Turnips to these, another seed sowing is made similarly in cold frames. The sowing of Turnips is an easy operation; their principal cultural requirements are ample ventilation, but not so much as to cause a check to growth, and judicious watering from the time of germination of the seeds. The Lettuces under the cloches will form a succession to those grown in frames. Any decayed leaves should be removed from the plants. When the *Cos* Lettuces are well established under the cloches, fresh air may be admitted by pressing the soil under the rim of each cloche either with the closed fist or a block of wood. This aperture is kept open during the whole time the plants are growing. Attention must now be given to the shading of the cloches with mats, which should be placed over the glasses for two or three hours during the brightest part of sunny days.

NURSERY BEDS. The plants of the first batch of Melons that were potted early this month have formed their third leaves. They are stopped after the second leaf, and the cotyledons are removed close to the stem, an operation that requires to be done carefully and with a sharp knife. The plants will be ready for planting in their final quarters within 10 or 12 days from this date. The other batches of Melons should be potted when they are ready, and the pots plunged in a good hot-bed, which is preferable at this season to a greenhouse. Nursery bed utilised for Melons can be used for a second batch by turning over the material and adding some fresh manure. Tomatos raised from seeds sown early in March are ready for pricking out. Good, clean loam is placed in a frame on an old manure bed, and the plants are pricked out 200 to 250 per light. The frames are covered at night till the plants are well established. Plants of the main batch of Celery intended to be planted out in June behind the Cauliflowers that are growing at present in the hot-beds, should be inserted in a mild hot-bed. The best varieties for the purpose are *Chenu* and *Long Winter Green*; the red sorts are not suitable for planting on old manure beds, as the plants grow thin and leggy. The Cauliflowers pricked out under cloches should be allowed ventilation, for the plants must be sufficiently hardy in three or four weeks for planting out. A small hot-bed 6 inches thick is being formed for pricking-out under cloches the Celery that was sown in the middle of February.

OPEN-AIR CROPS. The Onions planted out last autumn are of a fair size, and the best plants may be marketed. Cauliflowers are planted amongst the Onions, six rows per bed of 11 feet. The Cabbages *Ox-heart* are very forward this year. Their growth will be further stimulated by stirring the ground; a slight watering will be beneficial in a week's time, should the weather be favourable. *Cos* Lettuce "*White of Paris*" is planted at this date, in the open, 14 to 18 inches apart, in richly-manured ground. Spinach is often sown, as an inter-crop, and gathered before the *Cos* Lettuces require the room.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

SALES FOR THE ENSUING WEEK.

MONDAY—

Herbaceous Plants, Hardy Bulbs, &c., at 12; Roses, Fruit Trees, Azaleas, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

The Beneficial Interest in the Lease and Goodwill of Cripps's Nurseries, Tunbridge Wells, on the premises, at 11.0, by Protheroe & Morris.

MONDAY, TUESDAY AND WEDNESDAY—

Clearance Sale of the whole of the Stock at Cripps' Nurseries, Tunbridge Wells, by Protheroe & Morris, at 11.30.

WEDNESDAY—

Hardy Bulbs and Roots, Perennials, &c., at 12; Roses at 1.30; Palms and Plants, at 5; at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

Border and Herbaceous Plants at 12; Roses, &c., at 1.30; a Collection of Established Orchids, at 12.45; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich—42°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, March 15 (6 P.M.): Max. 42°; Min. 31°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 16 (10 A.M.): Bar. 29.6; Temp. 44; Weather—Fair.

PROVINCES.—Wednesday, March 15: Max 44 Ireland S.E.; Min. 37° Yorkshire.

Though every gardener knows what is meant by a hot-bed, and most gardeners are acquainted with the manifold

uses to which a good hot-bed may be put, especially in the spring months of the year, nevertheless the numerous enquiries which are addressed to us on this subject demonstrate that many younger practitioners and amateurs are by no means always certain that they are employing the best methods for the construction of this indispensable garden adjunct. We give, therefore, the following hints on this subject.

Complete success in the making of a hot-bed depends upon close attention to certain details, any one of which may be easily overlooked by the inexperienced. It must not be thought that the beginning and the end of the operation consist in taking four or five loads of manure and throwing them up into a flat heap large enough to take the frame which it is intended to place upon the bed. Much more care is needed in the construction of a serviceable hot-bed, although it is true that any heap of fresh manure, however roughly it may be put together, will answer the purpose after a fashion and for a limited time. The art of hot-bed construction lies in the ability to construct a heap of fermenting material that shall last not for a few days only, but for several weeks, or even longer. An improperly formed hot-bed may appear satisfactory enough for a day or two, but

the chances are that, within a week after it has been covered with the frame, the heat either increases to a dangerous degree or subsides suddenly until it is useless. In either case the plants in the frame are likely to suffer before it is possible to remedy the mistake that has been made.

Undue haste is probably responsible for nine out of every ten failures in hot-bed making. If the manure is quite fresh, as it should be, it needs a fortnight's treatment before it is ready to be formed into a bed. It should be prepared in some place under cover, for much rain may spoil the material by making it so soppy that it decomposes too rapidly and heats too fiercely. The whole of the manure must be thoroughly sweet before it is made up into the bed, and this can only be accomplished by frequent turnings. The turning over of the manure must be continued until the heap ceases to steam at the top during forty-eight hours after the last turning. It is difficult to describe the exact condition in which the manure should be when it is ready to be made up, but when, a day or so after its last turning, the heap appears to be pervaded by a gentle heat, the material is free from any rank smell, and is neither mouldy from overheating nor so wet that moisture can be squeezed out of it, then it may be said that the time has arrived for the making of the bed.

In the actual construction of the hot-bed two faults are common. One consists in making it too small; the other in not building it high enough round the edges. In either case valuable heat is lost. The edges should project for at least 18 inches beyond the frame, and the bed, from a space of 2 feet all round from its edge, should be built higher by 6 inches than the central square. This allows for the sinking due to the weight of the frame. Opinions differ as to the advisability of treading the hot-bed with the foot or of merely beating it firm with the fork. If leaves are used in conjunction with the manure a very good plan when manure is dear or difficult to obtain—or if the material contains more than half its bulk of long straw, then treading is likely to be not only necessary but conducive to the maintenance of heat in the bed for a long period. On the contrary, if the material is on the short side, it will be best not to tread it at all, since after being beaten with the fork the material will sink enough by its own weight to make a good, firm bed. After the frame is put on the bed, the temperature must be watched carefully, and the soiling of the bed should not take place until the thermometer shows that the temperature has ceased to rise.

A great deal depends upon the situation of the bed, but if the preparation has been thorough, and the situation is sheltered from the coldest winds, there ought to be a surface shade temperature when the frame is closed of about 75° Fahr. If the thermometer shows a reading much above this, the bed is too warm within;

and if it is much below, it is proof that the heat is declining faster than is desirable. In the former case, leaving the lights off for a day or so may do all that is necessary to prevent over-heating; in the latter contingency, some fresh and hot manure, built up all round the frame, will arrest the too rapid escape of heat from the bed, or a gentle application of water at about 100° Fahr. may be given inside and out. This latter is the easiest way of resuscitating a hot-bed that shows a tendency to cool, but if the watering is overdone, more harm than good ensues. Two gallons of water is quite enough to induce a rise in temperature in a bed measuring 9 feet by 7 feet, and the soil should be put on immediately after the watering.

A well-made bed seldom, however, needs any such treatment until it has been in existence for several weeks, when it will be necessary to encourage the heat if the bed is still wanted. To do this, as much of the sides of the bed as can be safely removed should be replaced by fresh manure, starting wide at the bottom and building right up to a point all round the upper edges of the frame. Oak and Beech leaves, or lawn mowings, may be used for the purpose of mixing with the manure, and we have always found that beds containing a good proportion of leaves have better lasting qualities than those formed exclusively of stable litter. The leaves should not be used too dry or the fermentation will be hindered.

Hot-beds retain their heat much longer if the sides and ends are cased with soil at the beginning, after the manner of a mushroom bed. If it is intended to do this, the edges must, of course, be built on the slope in the first instance, but they should be finished off flat at the top, as the platform thus provided will come in most useful during the spring and summer as a propagating bed for all kinds of plants which benefit from a gentle bottom heat. Miniature frames can be constructed over these beds with a few boards and pieces of glass for making the most of something, the original construction of which entailed considerable trouble and expense.

FLOWERS IN SEASON.—Mr. J. TAYLOR, Hardwicke Grange Gardens, Shrewsbury, has forwarded a seedling *Clivia* (*Imantophyllum*) with exceptionally large and brightly-coloured flowers. Accompanying the seedling was a truss of the ordinary variety, but its flowers were inferior to those of the seedling. Mr. TAYLOR supplies the following particulars:—The plant was grown in a pot of 6 inches diameter, and was raised from seed sown four years ago. The seeds of *Imantophyllum* take some considerable time to ripen, and should be sown in bottom heat early in the spring of the year after gathering. The plants should be kept growing in dry heat for a year or two, and when they have reached a flowering size, they should be placed in a house having a temperature of about 50° or 60°, and afforded water sparingly. A batch of the plants at Hardwicke Grange is introduced into heat every few weeks to supply flowers from mid-winter to spring. During the summer the plants are stood in frames; each day they are syringed and the lights closed early in the afternoon. In the autumn they are grown in vineries, and kept on the dry side until required for forcing.

APPOINTMENTS AT KEW.—The Lords Commissioners of His Majesty's Treasury have sanctioned, on the recommendation of the Board of Agriculture and Fisheries, the transfer of the foremen and storekeeper in the Royal Botanic Gardens from the temporary, to the established staff, and Civil Service certificates have been issued for the storekeeper, Mr. G. DEAR, and

the foremen, Messrs. W. IRVING, C. P. RAFFILL, A. OSBORN, T. W. TAYLOR, and J. COUTTS. Mr. HAROLD GREEN, a member of the gardening staff, has been appointed by the Secretary of State for the Colonies, on the recommendation of Kew, assistant superintendent of the Botanical and Forestry Department, Hong Kong. Mr. HARRY DODD, Curator of the Botanic Station at Onitsha,

Southern Nigeria, has been appointed by the Secretary of State for India in Council, on the recommendation of Kew, a probationer gardener for service in India.

ROYAL WARRANTS.—The Royal Warrant of Appointment, as hothouse builders and heating engineers to the KING, has been conferred on Messrs. MACKENZIE & MONCUR, LTD., Edinburgh and London. Messrs. DANIELS BROS., LTD., Norwich, have received the Royal Warrant of Appointment as seedsmen to the KING. This firm have also been appointed nurserymen to QUEEN ALEXANDRA. Mr. T. BLANCH, Church Street, Chelsea, has received the Royal Warrant of Appointment as van builder to the KING.

QUEEN MARY'S CORONATION BOUQUET.—We are informed by the Clerk of the Worshipful Company of Gardeners, Mr. ERNEST A. EBLEWHITE, that the bouquet which this guild will present to the QUEEN on the occasion of her Coronation will be composed of pink Carnations, Her Majesty having expressed a desire to this effect.

TRIAL OF ROSES AT BAGATELLE.—We are informed that during the past winter consignments of new Roses have been received at the Bagatelle Rosary (France), and that they still continue to arrive. No new varieties have been received from Italy, Spain, or Belgium, but Germany, England, the United States, Holland, Denmark, Luxemburg, and Switzerland have sent some remarkable novelties, which may be seen by those who visit the Rosary during the coming season. Those who have new varieties, and intend to send specimens, should despatch their five plants as soon as possible, as it is not expected that any will be received after the close of the present month. The trials of Roses at Bagatelle are inspected by all eminent Rose growers and the general public. Specimens should be sent, post paid, to the following address:—"Monsieur LE CONSERVATEUR DU BOIS DE BOULOGNE, 'Roseraie de Bagatelle,' au gare de Neuilly-Porte-Maillon-Seine."

LADYBIRDS AND APHIS.—The value of the ladybird in gardens is recognised in America, where we learn no fewer than 100,000,000 will be "trapped" within the next few weeks and sent to Melon growers and orchidists to wage war on the aphid. The ladybirds which are to be so employed have been hibernating in the snowdrifts about Towle, Placer County, U.S.A.; the trappers, who include the Superintendent of the State Insectary, hope to fill 500 cases with the insects.

CUT FLOWERS BY RAIL OR POST.—In a paper read before the joint meeting of the Illinois State Horticultural Society and State Florists' Association, and published in *The American Florist*, Mr. J. F. AMMANN makes a number of valuable observations on the consignment of cut flowers for carriage by rail. He recommends that, before being packed, cut flowers should be placed with their stems in water for as many hours as it will take them to reach their destination; if the journey is to be of 12 hours' duration, then they should be in water previously for 12 hours, and so on. Corrugated paper (cardboard) boxes are best for long distance transport. The box should be lined with thicknesses of paper according to weather. Each layer should be fastened down by twine, sewn over the layer, through and under the box, and the twine should be pulled tight and tied. Finally, Mr. AMMANN recommends that ice in small bags should be laid on the stems, even in cold weather, since, on arrival at their destination, cut flowers are almost certain to be put for some time in a warm place before being unpacked and supplied with water.

FIG. 75.—HIPPEASTRUM "QUEEN MARY": FLOWERS WHITE.

(Received R.H.S. Award of Merit on Tuesday last. See p. 172.)

BARR MEMORIAL FUND.—We have received information that Mr. HENRY B. MAY, the treasurer of the fund for promoting a memorial to the late PETER BARR, has received a donation of £100 from the Duke of BEDFORD, K.G. The committee will not close the fund until the Birmingham Daffodil Show has taken place in April.

THE FLOWERING OF THE ALMOND.—The first flowers on a tree situated in a favourable position in Wandsworth, five miles south-west of London, expanded fully on the 11th inst. Previous dates for the same tree are March 12 last year; April 1 in 1909; March 23, 1908; March 20, 1907; February 23, 1906; March 7, 1905; and March 21, 1904.

ASPARAGUS HATCHERI.—The new American Asparagus, named *A. Hatcheri*, appears, from a note and illustration in *Moller's Deutsche Garten-Zeitung* (No. 9, 1911), to be a considerable improvement on *A. plumosus nanus*. It is of stronger growth, the lateral branches are less delicate, and are borne more regularly. Under similar cultural conditions the newer form bears about three times as much foliage suitable for cutting as the older *A. plumosus nanus*.

MUSEUMS AND ECONOMIC BIOLOGY.—At the Bristol Museum a room has been set apart as an economical biology department, the necessary funds having been provided by Lady SMYTH, after whom the room is to be known. Many of the exhibits consist of farm and garden pests shown in their various phases. It is hoped that the department will prove of service to practical cultivators.

THE PROTECTION OF NATIVE PLANTS.—The fact announced in the January number of the *Selborne Magazine* that the Selborne Society proposes to take action with respect to the protection of British plants, will be welcome news to those who are interested in our flora. The Society has established a section to deal especially with this subject, and has appointed Dr. RENDLE, president, and Mr. A. R. HORWOOD (of the Leicester Museum), secretary. Mr. Horwood will be glad to receive offers of co-operation in this work.

GRAFT HYBRIDS.—When in 1826 M. ADAM, a nurseryman of Vitry, grafted *Cytisus purpureus* on the common Laburnum, he could not have guessed that he was starting a controversy which was to hold biologists for nearly a 100 years. DARWIN, DE CANDOLLE, and others added their contributions to the discussion, and Professor WINCKLER, of Tübingen, has lately proved by experiments the existence of such graft-hybrids. These results are so remarkable that a short account of them will be useful, though botanists will, of course, turn to the original paper.* The plants used were the Black Night-shade, *Solanum nigrum*, and the Tomato, *S. lycopersicum*. The latter is considered as belonging to the genus *Lycopersicum* by the Kew authorities. Wedge or saddle-shaped grafts were made from young plants and grafted reciprocally, and in both cases the union was readily formed. These grafts were then cut through at a point which left exposed the newly-joined tissue of stock and scion. In a damp atmosphere a callus was quickly formed on this surface, and in this new growth adventitious buds were formed. The development of these buds was encouraged, and though, naturally, most of them were either pure Night-shade or pure Tomato, growths were at last observed bearing every sign of a hybrid origin. Many shoots, however, were produced which were on one side Tomato and on the other Night-shade; these

monstrous growths are termed by WINCKLER "Chimera." The complete hybrids showed, however, a real fusion of parental characters, and the form named *S. tubigense* may be taken as a typical example. The Tomato has compound leaves, serrate leaflets, and is densely hairy. The Night-shade leaf is simple, not serrated, and with but few hairs. The hybrid leaf is simple, serrated, and densely hairy. The flowers are intermediate in size, but a strong yellow as in the Tomato. The fruit resembles the Night-shade, but is larger, and shows some red and yellow colouring. Seeds are set, but do not often reach maturity, and WINCKLER explains this as the probable effect of the quicker ripening of Night-shade fruits as compared with the Tomato. The inheritance of this "quick" factor from the former does not allow sufficient time for their development. Many other extremely interesting hybrids were developed, but space will not permit their description. A suggestion made by Professor BAUER as to the nature of these hybrids led to a careful cytological study, and a remarkable fact was discovered. The outer tissues were found to resemble one parent and the inner tissues the other. None of the cells was of real hybrid nature. As the wolf disguised in sheep's clothing, so in this hybrid: the Tomato is hidden beneath the Night-shade's epidermis. These cases of hybrids are considered by BAUER to be variations of the half and half hybrids described as "Chimeras," and it is therefore proposed to term them "Periclinal Chimeras." Of the great importance of these results as bearing on reversion, bud variations, and the study of heredity generally, it is needless to insist, and the further experimental work which these results are bound to stimulate will be awaited with great interest.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

ABUTILON THOMSONII FL. PL.—I am very much obliged to Mr. Truelove for his information about this form (see *Gardeners' Chronicle*, January 14, p. 29), for it is a valuable contribution to the history of garden plants. I venture now to remark that I should be deeply indebted to any reader for cuttings, and that I should especially be glad if American friends would note that this or the typical *A. Thomsonii* would be very acceptable from America in particular. Small plants could no doubt be transmitted by post in moss and some waterproof fabric. The object in having the common *A. Thomsonii* from a distance is to discover whether the different conditions likely to obtain here can so alter constitution as to provide the contrast upon which fertility may possibly depend. Self sterility in plants is no doubt for the purpose of ensuring cross fertilisation—and to secure it nature does make tremendous efforts—but no one has yet been able to explain how this valuable quality of self sterility comes about. Experiments (not mine) are now being made in the Cambridge Botanic Gardens for the purpose of obtaining information on the subject. It is possible that the doubling of the flower may have introduced a modification of constitution, so that the double form may be as useful for experiment as the typical plant received from a far distance. It is remarkable that so few are aware of the fact of self sterility. Instances are quite common. No case is known of a plant of *Chimera* that bore seed with its own pollen—I have made many

trials myself—the Composite indeed are frequently self sterile, and self sterility, I have no doubt, is the reason why many tropical plants that are cultivated in our houses refuse to set seed. That the highly organised Composite are almost invariably self sterile is evidence that self sterility is connected with an advanced stage of evolution, and that it is therefore an attainment. Like dioecism (in effect the same thing), it must be regarded, I think, as means to a valuable end. I am not at present interested in the white variegated *Abutilons*, but I should be glad to receive yellow variegated ones. *A. Darwinii tessellatum* and *A. vexillarium* variegatum would also be highly acceptable. *R. Irwin Lynch, V.M.H., Botanic Gardens, Cambridge.*

FORCING OF VINES.—Whilst not in any way wishing to criticise the excellent cultural advice given by Mr. Edwin Beckett in the "Fruits under Glass" calendar, I should like to say that during the past three or four years we have never syringed the vine rods when starting them into growth; the atmosphere has been kept moist by frequently damping the paths and syringing what plants happen to be put in the vineries. I find the buds break into growth equally as well as when the vine rods are syringed two or three times a day, but as soon as the leaves on the shoots begin to grow they are then lightly syringed, but not with sufficient force to wash off the winter dressing which was "painted" on the rods. I also have proved it to be quite unnecessary to hang the tops in a downward direction to check the flow of sap in either medium or late-started vineries. The vine rods, after being cleaned and dressed with a mixture of clay, soot, sulphur, and "Abol," are tied into their permanent places. I have never found any difficulty either in the vines failing to break into bud freely or in the plants making excessively strong top growth. *A. Jefferies, Moor Hall Gardens, Essex.*

—I am glad to know that Mr. A. Jefferies' vines break successfully without syringing and without the tops of the rods being lowered into a horizontal position. There are many gardeners who are not so successful, and it is to those my remarks will apply. I am convinced that syringing or spraying the vines with tepid water is of much assistance, especially on bright days, equally as much so as an April shower to the growth of outside vegetation. The lowering of the tops of the rods especially in young, strong vines, does much to prevent the rush of sap to the top, and it thus encourages the lower buds to start away more freely. *E. Beckett.*

EGDWORTHIA CHRYSANTHA.—This uncommon plant is now finely in bloom on a south wall. It is a Daphne-like shrub with terminal flower-heads, similar to a *Daphne*. The flowers are yellow when open and exceedingly fragrant. The plant flowers when quite destitute of leaves. It needs no special treatment beyond plenty of water during dry weather, for it is in September that the flower-buds are formed. It flowers very profusely, well-nigh every tip producing a flower similar to the one I enclose for inspection. *W. A. Cook, Leonardlee Gardens, Sussex.*

SKIN IRRITATION FROM IVY (see pp. 139, 157).—I suffered from a severe attack 10 years ago, and another in the following year at Achuarrey Castle Gardens, when I was foreman gardener there. The attacks started about two days after beginning to cut the Ivy. I consulted a professor at the Edinburgh infirmary, and he said that it might attack one person, but that someone else working at the same job might not be affected. The professor gave me a prescription for ointment which cured me in a few days. His statement was correct, for two men working with me at the same time showed no signs of the skin trouble. *L. Mackay, St. Baldred's Tower, North Berwick.*

GREEN AND BROWN OAK TIMBER.—I can assure Mr. Elvcs that there is such a thing as green Oak timber, a nice piece of which I sent to the Editors of the *Gardeners' Chronicle* about four years ago, from an estate in Kent. Why the timber of certain Oak trees assumes a rich brown colour is also known, and reference to it will be found in the fifth edition of my *Practical Forestry*, which is now in hand. *A. D. Webster.*

* *Solanum tubigense*, ein echter Profblastard Zwischen Tomate und Nachtschatten." Ber. d. deutsch. botan. Gesell.-chaft. 27, 595-608, 1908.

NEW COLOURS IN SWEET PEAS.—Mr. Cuthbertson, in his lecture on Sweet Peas (see p. 159), concludes his remarks with a few words on the new colours that modern enthusiasts are endeavouring to produce. He mentions the "blue of *Salvia patens*, the scarlet of the *Geranium*, and the yellow of the *Coreopsis*" as examples of the deep shades of the colours that we are yet far from obtaining in the Sweet Pea. But supposing varieties are raised possessing the rich yellow of the *Coreopsis*, or the intense blue of *Salvia patens*, would it not impart an artificial look to these lovely flowers? The lavenders, pale blues, and creams at present existing are perfectly natural and attractive, but could the same be said of *Coreopsis* or *Salvia*-coloured blooms? Their value as cut flowers for dinner-table decoration would be sadly discounted, in comparison with the lovely shades of colour which we now have in varieties, such as Earl Spencer, Edna Unwin, Helen Lewis, and the numerous soft-hued pink and cream Sweet Peas. No such objection, however, could be laid against the appearance of a scarlet *Geranium*-coloured Pea, but in that direction success in recent years has almost been achieved. *T. H. Bolton, Powderham Gardens, Exeter.*

BULLFINCHES AND BLACK CURRANT BUDS.—We have long been familiar with the fondness of bullfinches for Gooseberry buds in the early spring, but I have never known these beautiful pests attack Black Currants in the way they are doing at the present time. Unfortunately, our bushes (like many more in this district) are badly attacked by the Black Currant mite, and the birds evidently prefer the affected and swollen buds to the unaffected ones. Many bushes are half denuded of buds, so we shall have ample proof (if the bushes are left standing another season) to see if the practice of picking the buds as advocated by some has any good effect as a cure for the pest. I am wondering if the presence of the mite has attracted the bullfinches to the Currants. *T. H. B., South Devon.*

"THE DEVELOPMENT OF BRITISH FORESTRY."—I had no particular wish to comment upon Dr. Groom's article in the *Gardeners' Chronicle* of February 13, in which he deals with two chapters in the above book, but in his reply to Mr. Elwes in your issue of March 4, Dr. Groom states: "Answers (to the problems connected with timber production) can only be obtained by the aid of men who have an analytical knowledge of the underlying principles, based upon adequate training in science and forestry." If Dr. Groom includes himself amongst the men so described, I think I am entitled to ask, in the interests of British forestry, upon what grounds he controverts my arguments, in the first place, and puts forward others of his own, in the second? The fundamental point which is dealt with throughout Chapter IV is clearly expressed on page 83 (the second page in the chapter) as follows: "For the forester, the climate of the country must be largely valued by its ability to produce the commoner timber trees, such as Oak, Ash, Beech, Pines, Spruce, Silver Fir, Birch, &c., of ornamental dimensions in the comparatively short period of 50 to 100 years, according to species. Judged on this particular basis, how does the British climate compare with that of France, Belgium, Germany, Holland, and others lying between similar latitudes?" The general conclusions I arrived at are, that within 500 feet to 600 feet of sea level, and, so far as the majority of trees were concerned, the British climate is as favourable to timber production as the climates of the above-mentioned Continental countries, but that the development of trees at high altitudes on the Continent has no parallel in Great Britain (page 99). I mentioned that Oak and Beech require to be specially favoured as regards soil and situation before they will produce the same bulk per acre or the same size in individual trees as may be seen in France, Belgium, or Central Germany (page 112). Throughout his review, Dr. Groom does not give a single instance or example to prove the inaccuracy of the above conclusions, but adopts the somewhat questionable method of quoting portions of paragraphs or sentences, and omitting, for reasons which are not in accord with the principles he lays down to Mr. Elwes, the full paragraph or context by means of which his quotations can alone be properly understood. He ignores facts, and represents physiological principles as arguments which

can easily be shown to be absurdities. Take, for instance, the following quotations, and corresponding arguments made use of by Dr. Groom. To begin with, he asserts that I have hazy impressions as to the physiological principles underlying the production of timber, because I assume that June, July, and August are the critical months for the growth and making of wood in the majority of forest trees. Is this assumption less reasonable than the one put forward by Dr. Groom that the elongation of twigs and thickening of stems takes place only during spring and early summer? When, and on what species have Dr. Groom's observations and researches been carried out if he seriously believes this statement? Or, again, what does he hope to prove by referring to the weak assimilation which may go on in conifers during the winter months, and what appreciable effect has it upon the production of timber, as compared with vigorous assimilation during July and August? Take, again, his first quotation, and the reasons he gives for dissenting from it. Properly and fairly given, this quotation reads thus: "But after that stage (the twentieth year or so) persistent wind, a clouded sky, and the absence of intense insolation tend to check the height, growth, and development of most species, and the result is a diminutive yield of timber per acre, in a rotation of 80 to 100 years, compared with that obtained in Continental forests. On cold soils and exposed situations this diminution is most marked, while in sheltered valleys and warm soils it may disappear altogether." Dr. Groom then refers to the supposed advantages of diffused light, but forgets that diffused light, when accompanied by strong winds and a temperature approaching the minimum for a particular species, may be an unfavourable factor. Unless growth can be rendered immune against the cold winds and frosts of winter, it is of little advantage to the development of a tree, and a clouded sky is not conducive to well ripened shoots at high elevations or on cold soils, as may easily be seen if one examines in spring the tips and corners of trees grown under such conditions. With regard to rainfall, Dr. Groom says: "This statement (as to summer moisture) might lead the lay reader to suppose that there must be an adequate rainfall during the growing season or even during the summer." I should say the lay reader would be perfectly justified in such a supposition, and would find himself in agreement with every practical man. Does Dr. Groom seriously believe that if the whole of our annual rainfall was confined to autumn and winter, that tree or any growth over the greater part of Britain would be satisfactory? Has he never seen the effect of a two months' drought upon vegetation in the British Isles, and does he not know that the only trees unaffected by it are those growing on damp and fairly deep soils? The existence of forests may depend upon annual rainfall, but their satisfactory growth must depend upon sufficient soil moisture during the summer or growing season, and on the majority of soils this can only be provided by rain during the summer. Whether my views and conclusions regarding the effect of wind in exposed slopes and at high elevations are justified on physiological grounds or not is an open question. Those who take the trouble to verify them or prove their inaccuracy by observation will have little trouble in coming to a decision in this point. But when Dr. Groom complains that I fail "to disentangle clearly the effects of climate, especially wind, and of soil," he is surely making a remarkable suggestion for a physiologist and forester combined. Is it not the most elementary fact that growth is the result of innumerable factors, both physical and chemical, and given an individual tree or plantation, who can possibly estimate the value of any individual factor or group of factors? Briefly expressed, soil and climate are inseparable from all tree growths in the British Isles, or, for the matter of that, anywhere, and the poorer the former, the better the latter must be to produce a given growth. At low elevations in the British Isles, and away from the sea coast, it is perfectly obvious that unsatisfactory growth is usually the result of unsuitable soil. But on the vertical limits of tree growth, corresponding to elevations of 1,000 to 1,500 feet in Britain, no such conclusion can be arrived at, and it is generally impossible to say whether climate or soil have been most potent in producing certain effects. Dr. Groom's idea that the unsuitability of the soil on mountain slopes can be remedied by preparatory

crops depends for its correctness upon various conditions, which are fully discussed in Chapter V. But if he expects to find the same methods of amelioration applicable to maintain slopes in the British Isles as may possibly be effective, in the course of several centuries, on bare rock, sand dunes, and semi-deserts, it is evident that his acquaintance with mountain slopes above the 1,000 feet line is comparatively limited. "Poor, shallow, or purely mineral soils" are comparatively gardens of Eden when contrasted with peat-covered slopes exposed to a westerly wind, although Dr. Groom appears to have his doubts about the existence of the latter. Judging from Dr. Groom's reply to Mr. Elwes, he apparently assumes, as so many theorists have done, that nothing has been accomplished in the way of experimenting with mountain land by tree planting. Apart from that ghastly failure in County Galway, which venture any practical man would have pronounced hopeless from the first, every hill range in the British Isles has been more or less planted within the last century or so, and we know at least something of the conditions necessary for profitable tree growth. Much more has, of course, to be learnt, but I doubt very much if the final conclusions arrived at will be so fatal, opposed to practical experience as Dr. Groom would have us to suppose. I regret having taken up so much of your space over this matter, but I think it is important to show the fallacy of Dr. Groom's reasoning when dealing with the British Isles alone. All individual factors of growth have a relative rather than an absolute value, and this fact is often forgotten by the theorist or scientist who fails to apply his principles and deductions to every day conditions of life. *A. C. Forbes.*

SOCIETIES.

ROYAL HORTICULTURAL

MARCH 14, 15.—All available space in the Hall was filled with exhibits at the meeting on Tuesday last, for, in addition to a magnificent display of spring flowers and Orchids, there were competitive classes for Hyacinths and other bulbs. Both the amexes were requisitioned for the accommodation of exhibits. A larger number of medals than usual was given by the FLORAL COMMITTEE, including a Gold Medal for a splendid exhibit of Alpines from the gardens of Sir EVERARD HAMPERO. The FLORAL COMMITTEE granted also one First-class Certificate and two Awards of Merit.

There was a remarkable display of Orchids for the time of the year, and numerous novelties were submitted for award, the ORCHID COMMITTEE granting one First-class Certificate and four Awards of Merit.

The NARCISSUS COMMITTEE sat for the first time this season. There were several groups of Daffodils, and one very large display of Tulips. The NARCISSUS COMMITTEE recommended an Award of Merit to a variety of Tulip.

The FRUIT AND VEGETABLE COMMITTEE found but little to occupy their attention, and this body made no Award to a novelty.

At the 5 o'clock meeting, in the Lecture Room, more than 90 new Fellows were elected, and the sixth Masters' Memorial Lecture was delivered by Mr. G. E. Scott Elliot, his subject being "The Origin of Varieties."

The exhibition was continued on Wednesday, and on both days, but especially on Tuesday, the press of visitors rendered an inspection of the exhibits a matter of great difficulty.

Floral Committee.

Present: W. Marshall and H. B. May (Chairmen); and Messrs. C. Blick, W. Bain, W. Cuthbertson, Ch. T. Druery, G. Renhe, W. J. James, E. H. Jenkins, W. Howe, Chas. E. Shea, Geo. Paul, Chas. E. Pearson, Chas. Dixon, John Dickson, C. J. Lucas, Junr., Jennings, J. F. McLeod, C. R. Fielder, Jas. Douglas, W. J. Bean, R. C. Notcutt, Junr., Green, J. W. Barr, A. Kingsmill, F. Page Roberts, Arthur Turner, Reginald Nevill, R. Hooper Pearson, and Ed. Mawley.

MESSRS. JAMES CARTER & CO., Raynes Park, staged a novel and attractive display in the form of a spring garden scene. The design was a bold one and well carried out, a grass sward adding considerably to the effectiveness of the exhibit. At the back was a shrubbery, in the foreground

of this being a broad border of spring bulbs in flower, with two fountains at intervals. In the centre of the grass plot was an old stone vase, filled with pink Tulips, and at the base a ring of white Hyacinths. Along the foreground were half-circular beds of Tulips and Hyacinths, in various colours, all the flowers being magnificent specimens. (Silver-gilt Flora Medal.)

Messrs. JAMES VEITCH & SONS, LTD., Chelsea, made an attractive display with finely-flowered varieties of Rhododendron (*Azalea*) indicum and other greenhouse plants, including *Polygala dalmaniana*, *Primula kewensis*, *Cineraria Feltham Blue* (of a lovely shade, and with narrow, revolute florets), a striking batch of *Hippeastrums*, some good *Imantophyllums* (*Chivias*), and small, well-flowered plants of *Streptosolen Jamesonii*. (Silver Banksian Medal.)

Mr. L. R. RUSSELL, Richmond, again made a bold and effective display with forced shrubs and Rhododendrons (*Azaleas*), a large group of tall plants of *Jasminum primulinum* at the back throwing the other subjects into greater prominence. In the foreground was a batch of *Franciscea calycina floribunda*, the plants being models of good culture. (Silver Flora Medal.)

Messrs. WM. PAUL & SON, Waltham Cross, exhibited species of *Prunus* and *Pyrus* against a background of *Camellias*. The group was exceedingly pretty, reminding one of a Japanese garden scene, the more attractive subjects being double-flowered Peaches, Almonds, and Cherries. (Silver Flora Medal.)

Mr. H. BURNETT, Guernsey, again displayed an exhibit of Carnations, all magnificent blooms, and unapproached for quality by any others in the show. The variety *R. F. Felton* was superbly displayed, and others that were specially good included *Alma Ward*, a peony-shaped flower of bluish shade; *Mrs. C. F. Raphael*, *White Enchantress*, *Mrs. Tatton*, and *Bridesmaid*. (Silver-gilt Flora Medal.)

Messrs. W. CUTBUSH & SON, Highgate, made a showy exhibit with Carnations, the following varieties figuring prominently: *Mrs. Fortescue*, bright rose; *F. Galsworthy*, a shade of rose suffused with lavender; *Lady Elphinstone*, pink; *Adna*, pale lavender, very fine; and *Countess of Bradford*, yellow, marked with rose. This firm also exhibited Alpines, including showy batches of the double-flowered blue *Hepatica*, *Primula rivalis*, a fine pan of *S. oppositifolia*, *Daphnoblagaiana*, *Kalmia glauca*, also shrubs in flower such as *Rhododendron Smithii aurea*, *R. Pink Pearl*, *Viburnum plicatum*, many sorts of *Lilac*, and other species. (Silver Banksian Medal.)

Mr. C. ENGELMANN, Saffron Walden, showed varieties of perpetual-flowering Carnations, the beautiful clove-coloured *Carola*, *Rex* (pink), *Beacon*, and *White Perfection* being the more conspicuous examples.

Messrs. STUART LOV & CO., Enfield, showed varieties of Carnations, a batch of *Acacias* in several species, and hybrid *Gerberas*.

Messrs. SUTTON & SONS, Reading, filled a table with varieties of *Primula obconica*, relieved with batches of the yellow-flowered *P. kewensis* and numerous *Palms* and *Ferns*. They showed the plants of *Primula obconica* in batches of colours, the finer sorts being of pink and crimson shades, whilst the white form was also very choice. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, displayed more than 40 varieties of *Zonal-leaved Pelargoniums*, including a new variety named *Scarlet King*, and a salmon-coloured form of the well-known *Paul Crampel* variety. (Silver Banksian Medal.)

The Earl of CLARENDON, The Grove, Watford (gr. Mr. Chas. Harris), showed *Violets* of the *La France* variety; the blooms and plants were extra vigorous, and a Cultural Commendation was awarded.

Mr. H. N. ELLISON, West Bromwich, staged splendid flowers of Messrs. Adnet's race of hybrid *Gerberas*, and varieties of *Freesias*, relieved with an assortment of *Ferns*. (Silver-gilt Banksian Medal.)

Messrs. G. MOUNT, LTD., Canterbury, exhibited the new pink *Rose Mrs. Geo. Sawyer*, a charming variety as shown in the bud stage; also others of the yellow variety *Lady Hill*. (Silver Banksian Medal.)

Messrs. R. GILL & SONS, Tremough, Falmouth, showed numerous trusses of *Rhododendrons*, many of the varieties being of their raising; also *Camellia reticulata*, *Erica codonoides*, *Dracena divisa vera* with variegated leaves, their new

Primula Winteri, *P. imperialis*, and other hardy flowers. (Silver Banksian Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, exhibited well-bloomed plants of *Rhododendron (Azalea) indicum*, a variety of greenhouse *Ferns*, and a large plant of *Asparagus tenuissimus*. (Silver Banksian Medal.)

The Marquis of SALISBURY, Hatfield (gr. Mr. Prime), showed well-flowered plants of *Lachenalia Nelsonii* and *L. tricolor*. (Silver Banksian Medal.)

Messrs. R. & G. CUTBERT, Southgate, also showed plants of *Lachenalia*, for which a Bronze Flora Medal was awarded.

Messrs. BLACKMORE & LANGDON, Bath, showed baskets of coloured *Primroses* and *Polyanthuses*.

Messrs. G. PAUL & SON, The Old Nurseries, Cheshunt, were awarded a bronze Flora Medal for an exhibit of *Roses* and flowering shrubs, these latter including choice varieties of *Lilac*.

HARDY PLANTS.

Sir EVERARD HAMBRO, K.C.V.O., Hayes Place, Hayes, Kent (gr. Mr. J. Grandfield), showed, as in former years, a superb exhibit of Alpines. The plants were all of choice varieties or uncommon species, and remarkable for their splendid culture as well as great size. Large pans were filled with such beautiful *Saxifragas* as *S. Bursariana*, *S. apiculata*, *S. Boydii*, *S. B. alba* (especially good), *S. marginata*, the rare *S. Petraschii*, *S. Strbyinii*, *S. Vandellii*, *S. Obristii*, *S. Boryi*, and *S. cochlearis*. We have seen nothing

FIG. 76.—SAXIFRAGA PETRASCHII.

finer exhibited in *Saxifragas* than these remarkable specimens. There were three large batches of *Primula denticulata*, *P. d. alba*, and *P. Cashmeriana*, these plants also being superbly flowered. The background was composed of well-bloomed *Rhododendrons*, *Kalmias*, and other shrubs mixed with *Daffodils*, whilst interspersed amongst the group were numerous Alpines, besides those enumerated, including batches of *Primula malacoides*, *P. Forbesii*, *P. floribunda*, *P. cortusoides*, the rare *P. cynoglossifolia*, *Gentiana*, *Shortia*, *Juncka Heldreichii*, and many more. (Gold Medal.)

Messrs. R. WALLACE & CO., Colchester, put up a rock-garden exhibit, arranging it in a very natural manner, and having suitable plants in bloom, including many species of *Saxifraga*, of which we noticed *S. Boydii*, *S. B. alba*, *S. Paulina*, *S. Petraschii*, and *S. latina*. (Bronze Flora Medal.)

Mr. CLARENCE ELLIOTT, Stevenage, arranged with excellent skill a rock-garden exhibit, miniature ravines being sheets of flowers of *Saxifraga Bursariana speciosa* (yellow), *S. apiculata* (white), and *S. oppositifolia* (mauve).

Mr. H. HEMSLEY, Crawley, displayed, on a rockery, varieties of hardy plants in flower, amongst which were good specimens of *Saxifraga Boydii*, and *S. coriophylla*, *Viola Bowles's Black*, *Iris reticulata*, *Publunaria rubra*, *Erythronium densum alba*, also dwarf shrubs such as *Cytisus Ardoinii*, and *Rhododendron racemosum*.

Messrs. BARR & SONS, King Street, Covent Garden, exhibited Alpines extensively, their *Crocuses* and *Anemones* being especially good; a pan of *Crocus purpureus grandiflorus* was remarkably fine. They also showed *Gerberas* in a variety of colours and a large collection of *Narcissi*.

Messrs. J. PEED & SONS, Norwood, showed Alpines in variety and a batch of well-flowered plants of *Lachenalia Nelsonii*.

Messrs. GEO. JACKMAN & SON, Woking, also exhibited seasonable hardy plants, including a remarkably fine batch of *Draba azoides*.

Other exhibitors of rock-garden plants were Mr. H. C. PULHAM, Elsenham; W. WARE, LTD., Feltham (Silver Banksian Medal); the Misses HOPKINS, Shepperton (Bronze Flora Medal); Messrs. G. & A. CLARK, LTD., Dover, this firm's coloured *Primroses* being remarkably fine; Mr. MAURICE PRICHARD, Christchurch, Hampshire (Silver Banksian Medal); Messrs. BAKERS, LTD., Wolverhampton, *Primula Mrs. J. H. Wilson* being excellent; Messrs. HEATH & SON, Cheltenham; Mr. JAMES BOX, Lindfield, the exhibit having bulbous flowers, some of them arranged in epergnes (Silver Flora Medal); and Mr. G. REUTHE, Keston, Kent (Silver Flora Medal).

FIRST-CLASS CERTIFICATE.

Adiantum "Glory of Moordrecht."—This plant, which was awarded an Award of Merit when shown on a recent occasion (see p. 77), was given the higher award of a First-class Certificate. From Mr. FABIVS, Redlands Nursery, Emsworth.

AWARDS OF MERIT.

Hippeastrum "Queen Mary."—This handsome *Hippeastrum* is shown in fig. 75. The flowers measured 8 inches across, and were white in the interior, with just a suspicion of colouring on the exterior of the large and effective segments. Shown by Messrs. R. KER & SONS. We believe that the plant has passed into the collection of J. Pierpont Morgan, Esq.

Saxifraga Petraschii.—This charming little hybrid is from a cross between *S. tombeanensis* × *S. Rocheliana*. It has compact, glaucous foliage, red tinged, glandular stems 2 inches high, and it bears three or four pure white flowers in each head. Shown by Sir E. HAMBRO.

Narcissus Committee.

Present: E. A. Bowles, Esq., (in the Chair); and Messrs. Robert Sydenham, Alex. M. Wilson, Charles Dawson, W. F. M. Copeland, Walter T. Ware, John Pope, F. Herbert Chapman, Francis Barchard, Harold A. Denison, W. W. Fowler, Joseph Jacob, W. Poupert, P. Rudolph Barr, George Engleheart, R. W. Wallace, W. Goldring, Charles T. Digby, E. M. Crosfield, Arthur R. Goodwin, J. T. Bennett-Poë, W. B. Cranfield, and Miss E. Willmott.

An imposing display of Tulips was staged by Messrs. R. & G. CUTBERT, Southgate, the exhibit extending the whole width of the Hall. There were 38 distinct varieties, shown in batches, the plants being well-grown specimens in pots. (Silver-gilt Banksian Medal.)

Messrs. CARTWRIGHT & GOODWIN, Kidderminster, showed varieties of *Narcissi*, having excellent flowers of such fine varieties as *Southern Star*, *Matthew Arnold*, *King Alfred*, *Barcarolle*, *Mrs. H. J. Veitch*, *Trojan Boy*, and *Fairy Queen*. (Silver-gilt Banksian Medal.)

Messrs. R. SYDENHAM, LTD., Birmingham, showed an extensive exhibit of *Narcissi*, having a splendid selection of the more popular varieties in well-grown blooms. We noticed *Lucifer*, with a fine, star-like perianth and beautiful, orange-coloured cup; *Weardale Perfection*, one of the finest of the giant bicolors; *Great Warley*, a large, creamy-white perianth that is sometimes more than 4 inches across; the yellow cup is of a proportionate size; *Una*, a very pretty variety because of the drooping habit of the flower, the lemon cup being tinged with orange; *Bandicoot*, with creamy-white perianth and pretty, canary-yellow cup, tipped with pale salmon colour; *Beacon*, the perianth being of a pale sulphur colour that sets off the large red cup; *Lila*, a white variety of the triandrous section; *Incognita*, distinguished by its large, flat, crinkled crown of orange-apricot colour; and *King Alfred*, a giant amongst trumpet *Daffodils*. In addition to the *Narcissi*, Messrs. SYDENHAM again showed bulbous plants grown in bowls with moss fibre.

Messrs. BARR & SONS, King Street, Covent Garden, had some interesting varieties of Daffodils, of which the more notable were Red Beacon, of the incomparabilis type, with a fine, orange eye; Czarina, a giant *Leedsii*; Admiral Makaroff, a giant trumpet Daffodil, with sulphur-coloured trumpet; King Alfred (this well-known variety was shown splendidly); Lycidas, an exquisite poet's Daffodil; Blackwell, a pretty Daffodil, of primrose colour, with a beautiful, orange-scarlet cup; also Elvira and Klondyke, both of the poetaz section. (Silver Flora Medal.)

Messrs. R. H. BATH, LTD., The Floral Farms, Wisbech, made a showy exhibit with bulbous plants grown in moss fibre. The various subjects were remarkably effective for floral decoration in dwelling-rooms, and the bowls were almost as pretty as the flowers. Crocuses and Hyacinths were growing and flowering with greater freedom than is often seen in ordinary flower-pots. (Silver Banksian Medal.)

Another showy exhibit of bulbous plants in fancy receptacles and planted in moss fibre was made by Messrs. CARTER PAGE & Co., London Wall.

A display of bright, clean blooms of Narcissi was put up by Mr. CHRISTOPHER BOURNE, Simpson, Bletchley. He showed Omar Khayyam, with pure white perianth and orange centre; Incognita, with broad, disc-like crown of apricot-orange colour; Dewdrop, with globular cup, tinged with apricot red; Lullaby (poeticus), with broad petals and clear yellow eye, edged with red; Tritoma, a crown of orange-red, set off by a creamy-white perianth; Walt Whitman, a fine poet's Narcissus; and Whitewell, with flat, yellow corona and white perianth. (Silver Flora Medal.)

Messrs. J. R. PEARSON & SONS, Chilwell Nurseries, Lowdham, exhibited varieties of Narcissi, having a large collection of varieties, including Lady Margaret Boscawen, Heroine (broad, white perianth and citron-coloured crown, with rim of orange—a beautiful flower), C. J. Backhouse, Duke of Bedford, Sir Watkin, Firebrand, Florence Pearson, Victoria, Van Waverin's Giant, and three choice sorts of the Giant *Leedsii* type in Vega, Nora Pearson, and Mountain Beauty. (Silver Banksian Medal.)

Mr. FRANK R. LILLEY, St. Peter's, Guedisey, showed varieties of Narcissi, spikes of the beautiful *Watsonia coccinea*, and vases of large-flowered Anemones.

AWARD OF MERIT.

Tulip Yellow Murillo.—A clear yellow, double variety, recommended for forcing. Shown by Mr. W. PROFITLICH, Twickenham.

COMPETITIVE BULB CLASSES.

The prizes presented by the General Bulb Growers' Society at Haarlem, brought together a wonderfully fine collection of Hyacinths. Most of these were staged in the annexe, where they attracted a constant stream of admiring visitors. In the division restricted to amateurs the competition was keen in every class, but the second division, for trade growers only, were disappointing from that point of view, as Messrs. R. & G. CUTHBERT, Southgate Nurseries, was the only competitors in each of the two classes; this firm was deservedly awarded the two gold medals for the best trade exhibits of forced Hyacinths. Messrs. CUTHBERT also secured this premier honour last year.

In the largest Hyacinth class for amateurs the Hon. VICARY GIBBS, Elstree (gr. Mr. E. Beckett), won the 1st prize, although the exhibit shown by the Duke of PORTLAND, Welbeck Abbey (gr. Mr. J. Gibson), was very close. So evenly balanced were the merits of the collections staged by these two competitors in the class for four pans of Hyacinths, that the judges awarded them equal firsts. This recalls an interesting discussion recently carried on in our columns on the awarding of equal prizes. We fully appreciated the difficulty of the judges' task; he would indeed be a bold man who decided which was the better of the two exhibits. Considering the number of varieties there are to choose from, it was interesting to note how few of them the exhibitors had utilised. In each class the varieties shown by the different exhibitors were nearly similar. It would seem that the average variety of Hyacinth does not possess much value from the exhibitor's point of view.

DIVISION I.—AMATEURS' CLASSES.

Eighteen Hyacinths, distinct.—This class was closely contested, the leading exhibits were of high merit, and the colours of the flowers were happily blended. The stout, erect, densely-flowered spikes were very fresh and exuded an all-pervading perfume. The 1st prize was awarded to the Hon. VICARY GIBBS (gr. Mr. E. Beckett). The outstanding varieties in this exhibit were La Victorie and Garibaldi (red), City of Haarlem (yellow), Correggio (white), Jacques (an immense pink truss), and King Menelik (dark purple); 2nd, the Duke of PORTLAND, Welbeck Abbey (gr. Mr. J. Gibson), with Capt. Boyton (a gigantic pale blue spike), Jacques, La Grandesse (white with very large flowers), and Ivanhoe (dark blue); 3rd, A. HANSON, Esq., Ivanhoe, Wavertree, Liverpool. This exhibit was shown in smaller pots, which gave it a more decorative value, though the spikes of bloom were not quite so good. In this collection the variety Lord Balfour was specially noticeable.

Twelve Hyacinths, distinct.—Again the chief exhibit was shown in unduly large flower-pots. Although the spikes of bloom were fine, they were not so even as those in the preceding class. Some competitors were evidently more fortunate than others in their supplies of moss for covering the soil. Unless the moss is green and good its use is detrimental rather than decorative. The 1st prize was won by the Marquis of SALISBURY, Hatfield, Hertfordshire (gr. Mr. H. Prime). The varieties which specially attracted notice were La Victorie, City of Haarlem, Jacques, Electra and Schotel, a pale porcelain-blue variety; 2nd, J. R. DIXON NUTTALL, Esq., Prescott (gr. Mr. J. W. Barker); Lord Herby (a beautiful rose-pink), Menelik (the best of the dark sorts), and Correggio were amongst the finest spikes; 3rd, Lord HOWARD DE WALDEN, Saffron Walden (gr. Mr. Vert).

Six Hyacinths, distinct.—It was pleasant to see the plants in this class grown in more proportionate pots. In the leading collections the yellow-flowered varieties were the weakest. The remaining sorts were a repetition of those seen in the larger classes. The 1st prize was awarded to Lord HILLINGDON, Sevenoaks (gr. Mr. J. Skelton), with Schotel, very fine; 2nd, Mr. H. FAIRBairn PHILLIPS, Edenbridge (gr. Mr. H. Spittle); 3rd, F. HARRISON, Esq., Wavertree (gr. Mr. W. Betley).

Four pans of Hyacinths, 10 roots of one variety in each pan.—The schedule required the blooms of each pan to be of distinctly different colour to those of the other three pans. This class occupied a large central table, and made a bright and more attractive display than the exhibit of bulbs in pots. The leading collections had evidently been grown under perfect conditions. Equal 1st prizes were awarded to the Hon. VICARY GIBBS and the Duke of PORTLAND. The Welbeck Abbey exhibit consisted of City of Haarlem (exceedingly fine), King of the Blues, La Victorie, and La Grandesse (a large white spike with immense individual flowers). Mr. GIBBS's exhibit comprised similar varieties, except that the white was represented by Correggio, in which, if the flowers were smaller, the spikes were more compact. 3rd, The Marquis of SALISBURY. This fine collection was shown in green-painted pans.

DIVISION II: TRADE GROWERS.

As previously stated, the only exhibit of 100 Hyacinths in 25 varieties, four blooms of each variety, was one from Messrs. R. and G. CUTHBERT, which comprised a splendid collection, tastefully arranged. Of the varieties shown by the amateurs, Jacques and Schotel were here finely represented. King Alfred, Lord Balfour and Rose à Merveille were also exceedingly meritorious.

One hundred and twenty Hyacinths, in 12 varieties, in pans, 10 roots of one variety in each pan.—Here, again, Messrs. CUTHBERT were the only exhibitors. Their 12 pans made a charming display.

BULBS GROWN IN MOSS FIBRE.

The three remaining competitive classes were restricted to amateurs, and were for bulbs grown in moss fibre or similar material (not carted), and without drainage. The prizes were given by Messrs. Robert Sydenham, Ltd.

Six single Hyacinths, to be selected from 13 given varieties.—These were pleasantly shown in

the customary, wide-mouthed, green-coloured receptacles. An occasional plant had evidently suffered from excess of moisture at the root, but on the whole the plants were very creditable. The prizes were awarded as follow:—1st, Miss C. A. MICHELL; 2nd, Lady TATE; 3rd, Miss E. M. RAWLINS, Northampton; 4th, Hon. Mrs. BARING, Winchester.

Six vases of Tulips.—Any number of bulbs might be grown in a vase, but the varieties were to be selected from 13 given kinds. The Tulips, which were arranged between some of the Hyacinths, presented a gay appearance. These were the most meritorious of the fibre exhibits. The 1st prize was won by Lady TATE, Streatham (gr. Mr. W. Howe), whose collection included Queen of the Netherlands, Rose Gris de Lin, Duchesse de Parma and Prince of Austria; the names of the last two varieties had become transposed. 2nd, Lady TATE, whose Rose Gris de Lin was literally a vase full; 3rd, Hon. Mrs. GUY BARING.

Six vases of Narcissi.—Any number of bulbs were admissible in a vase, but the sorts must be selected from a given list. The competition here was very keen; the vases were full of well-grown bulbs. The 1st prize was won by Miss E. M. RAWLINS with C. J. Backhouse, Victoria, and Mme. de Graaff very fine. 2nd, Lady TATE. This collection had the additional merit of possessing labels easily seen and read. Victoria, Blood Orange and Horace were the outstanding sorts. 3rd, Hon. Mrs. GUY BARING.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), Sir Jeremiah Colman, Bart., W. Cobb, R. G. Thwaites, Gurney Wilson, F. W. Moore, A. A. McBean, T. Armstrong, J. E. Shill, J. Cypher, W. H. Hatcher, A. Dye, H. G. Alexander, W. H. White, H. Ballantine, W. Bolton, F. M. Ogilvie, W. P. Bound, J. Charlesworth, J. S. Moss, and R. Brooman-White.

Messrs. CHARLESWORTH & Co., Haywards Heath, were awarded a Silver gilt Flora Medal for a fine group containing several good novelties, the best of which, the new *Odontoglossum Jeanette* (Rossii rubescens × amabile heatouense) securing the only First-class Certificate given (see Awards). The centre of the group was of Phaius Norman, one of the handsomest and most floriferous hybrids, in great variety. At one end was a fine selection of hybrid *Odontoglossums*, including the elegant *O. Sylvia* (cirrhosum × Rolfeae). These were arranged with scarlet *Odontiodas*, various *Cattleyas*, *Laelio-Cattleyas*, &c. The other end was of fine forms of *Odontoglossum crispum*, *Dendrobium Jamesianum*, the violet-lipped *Zygocolax Charlesworthii*, *Laelio-Cattleya Myra*, and the very handsome *Blasio-Cattleya Veitchii* King Edward VII.

Sir JEREMIAH COLMAN, Bart., V.M.H., Gatton Park (gr. Mr. Collier), was awarded a Silver Flora Medal for a pretty group of hybrid *Dendrobiums* raised at Gatton Park, and other interesting Orchids. The *Dendrobiums* were uniformly good, especially *D. Princess Patricia* Commaught, *D. Lady Colman*, one of the handsomest and most perfect in form, and *D. Margery Tyrrel* Giles. A fine white form of *D. melanodiscus*, with violet centre, was also shown, and the singular species *D. Hodgkinsonii* and *D. cucumerinum*, with short, fleshy, spiny growths and small fragrant flowers. Several handsome hybrid *Lycastes*, the pretty little *Maxillaria sanguinea*, *Pholidota chinensis*, and other species were also included, together with an elegant hybrid, *Odontoglossum Lady Roxburgh* (cirrhosum × perculum) nearest to *O. cirrhosum* in form.

Messrs. SANDER & SONS, St. Albans, secured a Silver Flora Medal for an effective group containing several fine novelties (see Awards). The *Odontoglossums* were well represented, and among other good *Laelio-Cattleyas*, L.-C. Firebrand (L.-C. highburyensis × C. Trianae) gave a brilliant colour effect. *Chysis Chelsonii*, *Cirrhopetalum acutifolium*, *Cattleya Jucunda* (labiata × Schroderea), *Schomburgkia undulata*, and some good *Cymbidiums* were noted.

Messrs. J. CYPIER & SONS, Cheltenham, staged an effective group, for which a Silver Flora Medal was awarded. The *Dendrobiums*, *Cypripediums*, and *Odontoglossums* were well shown, and *Miltonia Bleuana grandiflora*, some very fine

Cattleya Trianae, *Laelio-Cattleya Lady Miller*, the very fine *Cypripedium Bridgeri*, and *C. aureum Surprise*, a selection of *Masdevallias* and *Cymbidiums*, some bright-coloured *Sophro-Cattleyas* and finely-flowered *Dendrobiums* were also well displayed in the group.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, were awarded a Silver Flora Medal for a fine group, in the centre of which was a grand specimen of *Odontoglossum navium* with seven spikes, bearing collectively 216 flowers, surrounded by a very showy selection of good forms of *O. crispum*, *O. amabile*, *O. Ossulstonii*, &c. With these was a selection of *Dendrobiums*, one of the best being *D. nobile Armstrongiae*, a large white flower with deep violet centre. Amongst the *Cypripediums* was a new hybrid between *C. Euryades*, and *C. Godefroyae leucochilum*, an attractive novelty, *C. Mandie giganteum*, certainly the largest form yet shown, and others of excellent merit. The nearly black *Masdevallia chimera Roezlii* and other *Masdevallias* were also included.

Messrs. STUART LOW & Co., Bush Hill Park, Enfield, were awarded a Silver Banksian Medal for a group containing several fine specimens of their large type of *Dendrobium Wardianum* and *D. crassinode*, including the white forms, *D. atro-violaceum* bore five spikes, *D. aureum* had many of its violet-scented flowers, and *Cirhopetalum Mastersianum*, *C. picturatum*, *Masdevallia Schröderiana*, *M. triangularis*, and some *Laelio-Cattleyas*, &c., were remarked.

Messrs. J. & A. A. McBEAN, Cooksbridge, staged a very pretty group, for which a Silver Banksian Medal was voted. At the back were a good form of *Cymbidium eburneo-Lowianum*, several of the white *C. eburneum*, and good *Cattleya Schröderae*, the best and most distinct of which was the variety *dellense*, *Scarlet Epiphronitis Veitchii*, and a few hybrid *Odontoglossums*.

Mr. A. W. JENSEN, Lindfield, Haywards Heath, was awarded a Silver Banksian Medal for an effective group of showy Orchids, all of his own importation, and including a selection of a very fine type of *Odontoglossum crispum*, a very large *O. triumphans*, good *Cattleya Schröderae*, and *C. Mendelii*, and finely-coloured *Oncidium Kramerii*.

HAMILTON SMITH, Esq., Killoran, Church End, Finchley (gr. Mr. Coningsley), staged a group in which were two plants of *Lycaste Skinneri* Mrs. G. Hamilton Smith, one of the largest and best coloured *L. Skinneri*, *Cymbidium Balliae*, and *C. eburneo-Lowianum*, *Odontoglossum Edwardii*, *O. harvengtense* and *O. Mariettae* (*Lambeauium* × *Rolfae*), like a large spotted *O. crispum*, and other Orchids.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Staffes), sent the new hybrid *Odontoglossum Titania* (*Queen Alexandra* × *crispum Leonard Perfect*), a very large and remarkably coloured hybrid, the sepals and petals having densely-set, purplish-red markings, the tips being primrose-yellow and the large white lip having a distinct purple base and yellow crest.

J. B. SEATLE, Esq., Fairfield, Putney (gr. Mr. Paice), showed a small plant of a well-marked hybrid *Odontoglossum*.

HENRY A. INNES, Esq., Croft Spa, Yorks., sent *Odontoglossum eximium Monkend* variety, a very handsomely blotched flower; *Cypripedium villosum Stewartii*, and the finely-coloured *Laelio-Cattleya Dominicana Monkend* variety (see Awards).

The Rev. J. CROMBIE HOLME, Clayton-le-Moors, Aclington, sent *Cypripedium Johnsoni* (*Rothschildianum* × *philippense*) in good form.

The Hon. Mrs. FOLEY, Backham, Fordingbridge, sent a very fine plant of *Ansellia africana*, with many spikes; the pretty *Lissochilus purpuratus*, *Eulophia gracilis*, with erect spikes of greenish flowers, *E. lurida*, and *Megacalium* species out in flower.

R. BINGHAM-WHITE, Esq., Arddaroch, Garelochhead, showed two spikes of the handsomely blotched *Odontoglossum crispum Mercedes*, and one spike of a fine white form.

WILLIAM BOURN, Esq., Warrington, submitted a spike of *Dendrobium* of the *D. atro-violaceum* section, imported with *D. Ashworthiae*.

JOHN S. MOSS, Esq., Wintershill House, Bishop's Waltham, showed a fine, many-branched spike of a hybrid *Odontoglossum*, and a first inflorescence of a new rose-pink hybrid, with purplish-rose markings.

Major E. C. ROGERSON, Harpenden, showed *Odontoglossum eximium Ethel Rogerson*, a very handsome and richly-coloured flower.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum Jeanette (Rossii rubescens × *amabile heatonensis*), from Messrs. CHARLES-WORTH & Co.—Another happy combination of the *O. Smithii* section, and with quite new features. As with all hybrids of *O. Rossii* that species predominates, but the two parts of *O. crispum* give size, and the one part of *O. Harryanum* (both got through *O. amabile*) helps to give firm texture. The sepals and petals are densely marked with claret purple, the tips being tinted rose. The extraordinary labellum has an almost circular front of a carmine-rose colour, and the base has a singular yellow blotch around the similarly-coloured crest. The spike bore several fine flowers.

AWARDS OF MERIT.

Cymbidium Alexanderi (eburneo-Lowianum × *insigne-Sanderi*), from Lieut. Col. Sir GEORGE L. HOLLARD, K.C.V.O., Westonbirt (gr. Mr. H. G. Alexander).—Although in an immature condition, this new hybrid gave evidence of excellent quality, the flowers being as large as those of *C. insigne*, and similarly coloured. Sepals and petals broad, white, tinged with pink, and with rose lines. Lip large, white, blotched with blood-red in front, and striped on the side lobes.

Cymbidium Gottianum (eburneum × *insigne-Sanderi*), from Messrs. SANDER & SONS, St. Albans.—In this worthy hybrid, *C. eburneum* was the seed-bearer, and the flowers resemble that species more than the other. They are white, with a faint green tint on the sepals, with ruby-purple spotting on the front of the lip, and broken lines of the same colour on the side lobes.

Odontoglossum mirum Bruggense (crispum blotched variety × *Wilckeanum*), from Messrs. SANDER & SONS.—Resembling a very large and finely-formed, blotched *O. crispum*. Flowers with the segments heavily blotched with claret purple, with some white showing on the lip and tips of the other segments.

Laelio-Cattleya Dominicana Monkend variety (L. purpurata × *C. Dominicana*), from HENRY A. INNES, Esq., Croft Spa, Yorks.—Flower large; sepals and petals purplish-lilac; lip fine, deep-claret colour.

Fruit and Vegetable Committee.

Present, G. C. A. Nix, Esq. (in the Chair); and Messrs. H. S. Rivers, J. Harrison, W. Crump, J. Jaques, G. Reynolds, P. C. M. Veitch, H. Markham, W. Bates, A. Dean, T. Coomber, J. Vert, A. W. Metcalfe, A. R. Allan, J. Davis, W. Humphreys, G. Wythes, J. Gibson, E. Beckett, O. Thomas, G. Kelf, and W. Poupert.

Mr. W. POUPERT, Malsh Farm, Twickenham, showed varieties of Blubarb. The collection included remarkably fine stems of *Daws's Champion*, that had been forced. These were about 18 inches in length, and the exterior was richly coloured. There was other produce of the same variety from out-of-doors, to show its early cropping. *Hawke's Champagne*, grown under the same conditions, was also shown; whilst the flesh of *Daws's Champion* is red, that of *Hawke's Champagne* is white. Stems of *Royal Albert*, an old variety, were much smaller. Mr. POUPERT also showed roots of the varieties *Daws's Challenge*, the *Sutton*, *Victoria*, and *Limaucus*.

Messrs. SUTTON & SONS, Reading, set up a collection of vegetables of very high quality. The central feature was a fine cone of some three dozen white, solid heads of *Superb Early White Broccoli*. There were also dishes of *Early Paris Cabbage Lettuce*, baskets of the new and wonderfully early hearting *Cabbage Harbinger*, small and quite firm; clusters of *Dandelion*, *Chicory*, purple-tinted and lily-white *Seakale*; two mounds of *20th Century Mushrooms*, and bundles of the *Sutton Rhubarb*. (Silver Banksian Medal.)

W. RAUFAEL, Esq. (gr. Mr. W. H. Honess), Hopfield, Dorking, set up in boxes on a carpet of moss, excellent samples of *La Petite Noir Cabbage Lettuce*; these had been cultivated in cloches.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

(ANNUAL MEETING.)

MARCH 13.—The annual meeting of the above society was held on the above date at the Horticultural Hall. Mr. Charles H. Curtis presided, and about 20 members were present.

The Chairman, in moving the adoption of the report and balance-sheet, referred briefly to the excellent work of the society during the year, and strongly commended it to the notice of young gardeners. This was carried with acclamation.

EXTRACTS FROM THE REPORT.

"The membership has steadily increased. Seventy new members were elected during the year. Among the deceased members were Mr. W. Bunce, who joined the society in 1868, and who had the sum of £72 19s. 7d. to his credit in the society's funds; and Mr. Alexander Clark, who joined in 1885, and left £44 14s. 11d. to his nominee. The total amount paid out to nominees of deceased members was £147 10s. 4d. It is of interest to record that a sum of 30 guineas was paid out to a member who had been lapsed for 30 years. Another lapsed member received the amount 12s. 7d. due to him.

"The total amount of sick pay to benefit members during the year was £561 0s. 6d., as against £571 15s. the previous year.

CONVALESCENT FUND.

"Very few applications were made for assistance from this source. The subscriptions, including five guineas from N. N. Sherwood, Esq., V.M.H., amounted to £10 0s. 6d. and the payments to £8.

BENEVOLENT FUND.

"Subscriptions to the Benevolent Fund amounted to £233 10s. 1d., and the payments therefrom to £90 16s., the latter amount including the sums regularly paid to several members over 70 years of age, as well as a few grants made to members or members' widows, in great distress. A payment of £2 was granted to a necessitous member to assist him to pay a doctor's bill, and £3 was granted to a member's widow who was left in very straitened circumstances. In all cases the committee exercises its utmost discretion in making grants from this fund.

MANAGEMENT FUND.

"The strictest economy, consistent with the proper working of the society, has been observed in this department. The total management charges amounted to £222 9s. 7d., as against £195 15s. 10d. in 1909 and £192 19s. 10d. in 1908. The slight increase of annual expenditure is due to the actuaries' fee of £21 and £5 3s. for clerical assistance to the secretary.

WIDOWS AND ORPHANS.

"Reference was made in the last annual report to the suggestion brought forward at a recent annual general meeting for the establishment of a fund to provide for funeral expenses in case of any member who might have the misfortune to lose his wife by death. Actuarial advice was obtained upon this matter, with the result that as there were so many points of far-reaching importance involved, it would not be wise to lay any propositions before the members at the present time. The matter is, therefore, indefinitely in abeyance.

"The committee would again direct attention to the benefits of the Royal Gardeners' Orphan Fund, and begs support wherever possible for the orphans of deceased members of the U.H.B.P.S. Much good can be done by co-operative voting. A subscription of 5s. per annum entitles a subscriber to one vote at each election, and if a large number were to subscribe, the election of children of deceased members to the benefits of the fund would be practically assured.

STATE INSURANCE.

"A keen watch has been kept on all the statements and reports in the Press in regard to the tentative proposals of State insurance against sickness, and the committee has been in communication with the Chancellor of the Exchequer twice on this matter. A report and balance-sheet for 1909 was also forwarded to the Chancellor, with

a request that the committee be kept informed of any developments.

BENEFITS OF MEMBERSHIP.

The many benefits attaching to membership of the society are well known to the members themselves, although not all of them, as already pointed out, are taken full advantage of. But if the society is soon to hold that large place in the horticultural world it is meant to fill, then there must be greater effort on the part of private members. In return for a payment of 9d. per week, a member receives 18s. per week for six months if continuously ill for that period, and 9s. per week for a further six months if still ill (12s. and 6s. respectively if the subscription is 6d. per week). In cases of chronic sickness, 6s. and 4s. per week respectively are granted, and should a member be unable to follow his employment after attaining the age of 70 years, he receives a sum of not less than 5s. per week. After reaching 60 years of age, a member may withdraw a sum equal to double the amount of the interest on his deposit account in any one year, and thus, in times of stress, be able, in many cases, to pay his contributions to the society from the amount standing to his personal account in the books of the society.

"The financial stability of the society is beyond question, as it has now £38,800 invested."

The retiring members of the committee, Messrs. Burge, Stanbridge, Walker, and Bedford, were re-elected. On the proposal of the Chairman, seconded by Mr. J. Wheeler, Mr. W. Collins was complimented on completing 25 years' service as secretary to the society. He was re-elected unanimously.

Messrs. Gunner and Puzey were elected as auditors, and Mr. W. P. Thomson, who was, unfortunately, absent through illness, as treasurer.

At a meeting of the committee held immediately following the annual meeting, Messrs. C. H. Curtis and T. Winter were again elected as chairman and vice-chairman of committee respectively.

PROPOSED NATIONAL DAFFODIL.

MARCH 14.—The adjourned meeting held to consider the advisability of forming a National Daffodil Society, took place on this date, in one of the upper rooms of the Royal Horticultural Society's Hall, Westminster. There was a larger attendance than on the previous occasion, and the company was representative of trade and amateur growers. The Rev. George Engleheart again presided, and he referred to the circumstances which prompted the movement. He said that there was a feeling that all was not done that was possible to further the interests of Daffodils. At the last meeting, the feeling prevailed that, if existing organisations would provide what was wanted, there would be no need to form a society. The Narcissus Committee of the Royal Horticultural Society was a responsible body, and, through it, they had approached the Council of the Royal Horticultural Society.

Mr. Cranfield stated that he had been in communication with the chairman, Mr. Bowles, and members of the Daffodil Committee to ascertain their views, and he was invited to attend the meeting of the Daffodil Committee of the R.H.S. that morning. The Daffodil Committee passed the following resolution: "That the Council be asked if they are willing to grant the Narcissus Committee power to hold a two-days show in mid-April, to issue (through the Council) a *Year Book*; to issue a schedule of prizes (the Committee to find the cash prizes); and for the Committee to sub-divide itself into sub-committees for special purposes." The Council replied to this as follows:—"The Council, having considered the resolution sent up to them by the Narcissus Committee this day, are willing (1) to hold a two-days Daffodil show in April; (2) to issue a *Year Book* if the Committee supply sufficient and suitable material for the same; (3) to issue a schedule for the show, after receiving recommendations from the Committee thereupon; and (4) the Council consider all Committees competent to sub-divide themselves into sub-committees for special and topical purposes." Mr. Cranfield therefore proposed "that, in view of the resolution passed by the R.H.S. Council, on the recommendation of the Daffodil Committee, the

proposal to form a National Daffodil Society be postponed until it is ascertained how far the Daffodil Committee is prepared to go." A brief discussion ensued, and the proposition being put to the meeting, was carried.

SCOTTISH HORTICULTURAL.

MARCH 7.—The monthly meeting of this association was held in the Goid Hall, 5, St. Andrew Square, Edinburgh, on this date. The president, Mr. Massie, was in the Chair, and there was an attendance of 150 members.

A lecture on "Sweet Peas" (published in the last issue, p. 159), illustrated by coloured drawings, was delivered by Mr. Wm. Cuthbertson, J.P., of Messrs. Dobbie & Co., Edinburgh.

The exhibits included 23 varieties of Wall-flower from Messrs. DOBBIE & Co., Edinburgh; Hybrid Primulas (*P. obconica* × *stellata*), *Galanthus Elwesii*, *Sisyrinchium grandiflorum*, and *Helleborus niger major*, *H. orientalis*, *H. abchasicus*, *H. abchasicus grandiflora*, and *H. o. caucasicus*, from Mr. C. COMFORT, Broomfield, Davidson's Mains; flowers of *Rhododendron Nobleum* hybrids from Mr. A. JOHNSTONE, Hay Lodge, Edinburgh; *Richardia africana* from Miss BURTON, Polton; *Dendrobium nobleum* from Mr. R. WHANNELL, The Drum, Midlothian;

THE LATE JAMES GEORGE.

spring flowers from Mrs. ALGIE, Togher House, Co. Mayo; and Brussels Sprout "Solidity" from Mr. J. STAWARD, St. Fort, Newport.

Eleven new members were elected.

The meeting on April 4 will be devoted to the young members, who are invited to contribute short papers or notes on horticulture or allied subjects.

LAW NOTE.

LAVENDER A VEGETABLE.

At the recent Cheshire Assizes, a hawker, who had been sentenced to three years' penal servitude at Oldham for shopbreaking in 1906, was charged with being found on February 4 under such circumstances as to satisfy the Court that he was waiting the opportunity to commit an offence punishable on indictment.

Mr. Dowson, for the defence, submitted that there was no offence, as no pedlar's certificate was required for the sale of Lavender, because the Pedlar's Act exempted vegetables, fish, fruit, and victuals. Mr. Marshall, for the prosecution, argued that Lavender was not a vegetable as the word was usually understood.

Justice Lord Coleridge held that Lavender was exempted from the Pedlars' Act, and directed the jury to return a verdict of not guilty.

Obituary.

MR. J. GEORGE.—The death of this well-known horticultural sundriesman occurred on the 11th inst. in his 85th year. He enjoyed a wide circle of friends amongst gardeners, and visitors to the London flower shows will miss his presence. He was born at Faringdon, Berkshire, in 1826, where his father conducted a nursery and market-gardening business, making specialties of Dahlias and Pansies. He left home to become apprenticed in the gardens at Faringdon House, which were then in the charge of Mr. George Milne, and he made such progress that before he was 21 years of age he was engaged as a gardener at Warnford House, Sevenhampton, Wiltshire. Here he remained until 1850. During his tenure at Warnford, the place changed hands, Sir Charles Wetherall becoming proprietor in succession to Lady Warnford. His next situation was at Lee, near Blackheath, in Kent, where he remained for two years. Later he took over the management of the gardens of Miss Nicholson, of Stamford Hill, London. Here he remained for 14 years. When his employer took up her residence at Putney Heath, Mr. George was retained as gardener, and he served 30 years in the service of the Nicholsons. During most of his time he sold gardeners' sundries. He next opened a business as a horticultural sundriesman at Putney. With the aid of a chemist he brought out a nicotine fumigator, and a substance known as tobacco tissue. These were somewhat costly to prepare, so he used paper for soaking the nicotine properties, and this tobacco paper had an extensive sale, being largely employed in gardens until the introduction of the vaporising fluids now in general use. Besides insecticides, Mr. George engaged in the sale of manures, peat, and other sundries, in which he built up an extensive business. Mushroom spawn was one of his specialties, and he was one of the first to introduce wood wool for packing purposes. Mr. George, early in life, turned his attention to the raising of Pelargoniums, and many of the introductions of Messrs. Cannell, Paul, Lees and Smith, of Hornsey, were raised by him. At the Pelargonium Society's meeting in 1872, held in conjunction with one of the shows of the Horticultural Society, he excelled all competitors with seedlings, being first in the classes for 18 and 12 Zonal varieties, and for 18 and 12 hybrid Zonal varieties, besides winning four First-class Certificates. He also crossed the Ivy-leaved varieties, and from one of his double-flowered seedlings was derived the well-known variety *Souvenir de Charles Turner*, a sort still largely cultivated. The *Abutilon* is another plant which engaged Mr. George's attention, and in 1833 his collection of these flowers was said to be unsurpassed. He obtained numerous certificates for seedling *Abutilons*, sending out many varieties. Mr. George was one of the oldest members of the National Chrysanthemum Society, and exhibited at this Society's exhibitions for nearly 50 years. To Mr. George gardeners owe the introduction of dwarf *Tropeolums*, which at one time were extensively employed in "ribbon" borders. His wife pre-deceased him last year, and his second son, Henry Hammond George, died on January 25 last. We understand that the business will be continued by the two surviving sons.

DAVID MURRAY.—A famous Scottish gardener has passed away in the death of Mr. David Murray, late gardener to the Marquis of Ailsa, at Culzean Castle, Perthshire, for more than about 40 years. Mr. Murray commenced his gardening career at the age of 14 in Abercainey Gardens, Crieff. He was at Abercainey for a short time only, leaving there to become apprenticed in Blair Drummond Gardens. Like most other young Scottish gardeners of his time, he was ambitious to serve in the famous gardens of the Duke of Buccleuch, at Dalkeith, which were then at the height of their fame under the management of the late Mr. William Thomson. He entered Dalkeith and remained for six years, being engaged in the several departments of the establishment. At about this time Mr. Thomson started his nursery at Clovenfords, and he offered Murray the post of Pineapple grower, the culture of these fruits being a feature of the establishment. He accepted the post, and after serving for three years at Clovenfords Mr. Murray was offered the post of gardener at Culzean Castle,

where he remained, as already stated, for about 40 years. Mr. Murray was only 24 years old when he took over the management of the gardens at Culzean, and he retired about a year ago. He carried out many improvements in those extensive and beautiful gardens. Mr. Murray was a good all-round gardener, but he excelled particularly in vegetable and fruit growing. He was especially successful in cultivating Onions, and was the raiser of the well-known Ailsa Craig variety. The Onions which he showed at the Edinburgh Exhibitions about 20 years ago were always the object of special comment, and it is said that whilst other exhibitors arranged their bulbs on the orthodox plates, Mr. Murray showed his on a riddle, which was seldom found too large a receptacle to accommodate his great specimens. Besides Ailsa Craig Onion, Mr. Murray raised the well-known Culzean Curled Kale. Grapes grown at Culzean generally secured leading honours at the more important Scottish and other shows, and hardy fruits were equally well grown in these gardens. Mr. Murray's abilities as a gardener were recognised by the Royal Caledonian Horticultural Society, and this body awarded him the Neill prize in 1902. The funeral took place at Kirkoswald.

ROBERT MACKENZIE CROSS.—The death is announced of this veteran plant collector at the age of 76 years. Mr. Cross was born at Dumblarton in 1836 and, after serving in various gardens he came to London in 1860. Soon afterwards Mr. J. Smith, then Curator of Kew Gardens, procured an appointment for him to go to Ecuador to obtain the red-barked Cinchona (Quinine), and to establish it in the Neigherries, India, a mission in which he was highly successful. He continued his services in collecting other species of Cinchona. In 1875, he went to Panama for *Castilleja elastica*, and later to the Amazon River, where he collected seeds and plants of *Hevea brasiliensis*, both species being needed for the Rubber industry. Mr. Cross also introduced several interesting plants to British gardens, one of the best-known being the pretty scarlet *Masdevallia racemosa* (syn. *M. Crossii*). His importation of this species was not very successful, but later the plant was introduced in better condition, and it is now well represented in gardens. Mr. Cross was a most indefatigable and observant traveller, and his excellent constitution enabled him to pass safely through many unhealthy districts. He retired to Edinburgh, with the thanks of the Indian Government, and a few years ago went to reside at Torrance of Campsie.

TIMOTHY MCCARTHY.—The American papers record the death on February 10 last of Timothy McCarthy, for 35 years Superintendent of Swan Point Cemetery, Providence, U.S.A. Mr. McCarthy was a native of Ireland; he emigrated to America at an early age, and secured employment in Forest Hills Cemetery, where he advanced in authority and responsibility, until he was given the management of the cemetery at Swan Point.

J. H. HART.—We have received news of the death of Mr. J. H. Hart, F.L.S., who for 21 years was head of the Botanical Department at Trinidad, and who retired from that position in June, 1903.

GARDENING APPOINTMENTS.

Mr. CHARLES JAMESON, for 11 years and 3 months Gardener to J. W. SHAND HARVEY, Esq., Castlebridge, as Gardener to J. A. BROWN, Esq., Moredun, Paisley. (Thanks for 2s. 6d. sent for R.G.O.F. box.—EDS.)

Mr. CHARLES J. KEMPTON, for the past 23 years Gardener to A. MORE O'FERRALL, Esq., Ballyna, Moyvalley, Co. Kildare, as Gardener to the Right Honble. The Lord CLARINA, Elm Park, Clarina, Limerick.

Mr. H. RADE, for the past 8½ years Gardener to Mrs. GERARD NORMAN, Bishopstrow House, Warminster, Wiltshire, as Gardener to R. BRUNNER, Esq., Belmont Hall, Northwich, Cheshire.

CATALOGUES RECEIVED.

F. P. DIXON & SONS, LTD., Hull—Farm Seeds.
Wm. WATSON & SONS, LTD., Clontarf Nurseries, Dublin—Border, Alpine, and Rock-Garden Flowers.
J. C. SORBY, Clutha Place, Edgington—Mass-Extractor and Tennis-Court Market.
A. A. COOPER, Tinsdale, Sligo, Ireland—Flower-Seed, Alpine and Herbaceous Plants, Shrubs, &c.

* * * The Editors will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for reproduction in this Journal.

HELVINE SLEIROLA: Staffs. This plant is a native of Sardinia, and has been introduced to gardens during recent years. The name does not occur in the gardening books.

INSECTS IN A FERNERY: Cliveden. The insects are common weevils. See reply to W. L., p. 160.

MANURES FOR BULBS: P. D. W., Cornwall. Whilst every plant requires nitrogen, potash, phosphoric acid, and lime, yet different species have special wants at different stages of their development. All bulbous, succulent, and quickly-growing plants require in their early growth an abundant supply of available nitrogen and phosphoric acid. It is known that the roots, bulbs, and tubers, whether of Turnips, Onions, Lilies, Tulips, Narcissus, or Potato, are produced in the lighter, loamy soils which are charged with dung, and where there is comparatively little obstruction to the development of fibrous roots. It is in these classes of soil that the special benefits of the phosphoric acid in superphosphate or bonemeal have been most observable. Spent hops may be used in addition to the dung for the Potato crop, applied at the same time as the dung in order that the humus may become well incorporated with the soil before planting the bulbous crop. A green crop of mustard for ploughing in might be useful for the production of humus, and especially if the land is infested with wireworm. Spent hops are not of great value for hot-beds.

NAMES OF PLANTS: N. B. 1. *Eranthemum Portulaca*; 2. *Pennis serrulata*; 3. *Adiantum pedatum*; 4. *Zebria pendula tricolor*; 5. *Hamelia arborea*; 6. *Cotoneaster microphylla*.—*J. P., Kildare.* 1. *Toxophloeia spectabilis*; 2, specimen not found; 3. *Lavandula dentata*; 4. *Coleonema album*; 5. *Phillyrea decora*; 6. *Cornus capitatus*.—*Heather P. H.* *Erica carnea*.—*O. H.* 1. *Oncidium caudatum*; 2. *Epidendrum fragrans*; 3. *Brassia caudata*; 4. *Celia triptera*.—*Foreman.* 1. *Pteris arguta*; 2. *longifolia*; 3. *Adiantum hispidulum*; 4. *Lomaria gibba*; 5. *Blechnum corcovadense*; 6. *Adiantum formosum*.—*E. W. S.* A good form of *Imantophallum (Clivia) mutata*.—*J. J.* *Hel leborus fetidissimus*.—*Sarum.* *Ornithogalum nutans*.

R.H.S. FELLOWSHIP: W. C. Apply to the Secretary, Royal Horticultural Hall, Vincent Square, Westminster, for a form of application.

RICHARDIA WITH DOUBLE SPATHE: H. S. D. Double-spathed *Richardias* are not uncommon, but your specimen is interesting because of its second spathe.

SUMMER BEDDING ARRANGEMENT: A. R. There should be no great difficulty in making a satisfactory display in your flower garden with the choice of material you have at your disposal. For No. 1 design the following arrangement may be adopted with a prospect of getting a good effect. The centre or oblong bed may be planted with a mass of scarlet *Pelargonium* with a border of a variety having white margins in the leaves; the two round beds may have blue *Viola*; two outside (oblong) beds, *Calceolaria amplexicaulis* edged with *Dactylis glomerata*. These beds are too narrow for "dot" plants to be used with success. The club shaped bed (No. 2) could be planted with a groundwork of pink Ivy leaved *Pelargonium* dotted over thinly with a medium sized variety of white *Antirrhinum*.

TESTING SOIL FOR LIME: E. H. W. and R. P. In rough testing for lime, the soil is moistened with a little water, and some muriatic acid (spirits of salts) or strong vinegar added. If a perceptible effervescence takes place the gar-

dener may assume that a sufficient quantity of lime exists in the soil. If he wishes to know the amount of lime more accurately, 6 ounces of water and ½ ounce of muriatic acid must be poured upon 1 ounce of soil, the mixture left for one hour in a warm place, and a solution of ammonia (spirits of hartshorn) added, stirring the mass actively all the time until there is a pungent odour. The liquid must then be filtered through two or three folds of white blotting paper. The lime is contained in the clear fluid, and may be thrown down as a white mud by adding solution of carbonate of potash or oxalate of ammonia; the precipitate should then be collected on a paper filter, carefully washed, dried, and weighed. It is very simple to see if the amount of precipitate of lime is small, medium, or abundant. A deficient amount would be about a quarter per cent., while an abundant supply would range from 2 to 6 per cent. of lime.

THE ERECTION OF COMMERCIAL GREENHOUSES: P. S. By erecting your greenhouses early in autumn you would have time to work up a fairly good stock of plants of the kinds mentioned in your letter, such as Carnations, Chrysanthemums, and Roses, for marketing in the following year. Should you erect the proposed houses during the next two months, you will be enabled to work up a stock of saleable plants for marketing during the autumn and winter, and spring following. The dimensions of the houses—spans—that you require may range from 12 feet to 20 feet in width, and may be any length from 20 to 200 feet, with front upright sashes 3 feet wide and from 18 to 24 inch high for providing front ventilation. Ventilating sashes of the same dimensions should be provided on either side of the ridge, to which they should be secured at intervals of five panes (8 feet), the ventilators being all worked by Wolland's continuous gearing. The rafters, fixed at 18 inches apart, will admit of 21-ounce glass 18 inches wide, and from 16 to 18 inches long, according to the length of rafters used. Span-roofed houses 12 feet wide should have a stage 4 feet 9 inches wide fixed on either side of the longitudinal centre on a level with the wall plates to stand the plant on, thus allowing a central pathway 2½ feet wide. Wider houses will admit of a central stage as well as side and end stages being fixed the entire length of individual houses. Your proposed houses should be provided with from four to six rows of 4 inch hot-water pipings—four rows in the narrow houses and six rows in the wide ones. Houses of the above-mentioned dimensions will answer your purpose.

TOMATO, A FRUIT OR VEGETABLE: Correspondent. The portion of a Tomato plant used for consumption is a fruit. The reason for Tomatoes being usually termed vegetables may be found in the fact that they are generally consumed as vegetables rather than as fruits. This fact is not so singular as you appear to suppose, for several other kinds of fruit are spoken of as vegetables and considered as vegetables for the purpose of exhibition, such, for example, as Beans, Peas, Vegetable Marrows, Cucumbers, and others which will occur to you. It is scarcely necessary to go into the further question of the botanical names given to these several fruits. With respect to your second question, there is nothing to prevent you from showing Tomatoes in a collection of six kinds of fruit, provided there are no regulations as to the kinds of fruit to be exhibited. Whether it is good policy to include them is another question. A dish of Tomatoes might not gain so many points as a dish of Peaches, for example, or a good bunch of Grapes. In selecting kinds, whether of fruit or vegetable for exhibition, it is necessary to consider not only whether you are entitled or not to exhibit the particular kind, but also whether its comparative value is sufficiently high to assist you in your efforts to excel others competing in the same class.

**THE DALE NURSERIES,
BRAMPTON, CANADA.**

THE first impression which Canada produces on the visitor is fairly conformable with that which he had in mind before he set foot in the Dominion: a few great cities linked by the iron bonds of the railway and, lying between them, vast spaces dotted with great farms. The cities in particular impress the visitor. Huge, full of life, strenuous, with vastly high and sometimes fine buildings and uniformly ill-paved roads. Not all the cities are alike, however, as are our own great centres of industry. The Canadian cities have each a well-marked feature. Quebec, with its superb situation and long history, tells at every turn stories of romantic struggle between now-reconciled rivals. Its picturesque but well-nigh deserted riverside above the port speaks not only of Wolfe's wonderful adventure, but also of the decay of a great enterprise—that of lumbering—which, owing to the reckless felling of timber in the neighbourhood, is lost to that part of the province. Montreal has an elegance—apart from its business quarter—which is unique, and Toronto a

strenuousness and reckless disregard of a beautiful situation overlooking the lake that is reminiscent of the great cities of the States. Ottawa, the seat of the Federal Government, gives the impression of having outgrown a charming infancy and of becoming, with its clanging trams and aggressive night-lit electric advertisements, too much a commercial centre and too little a fit situation for leisured statesmanship. But all these cities have in common, a genial welcome for the stranger.

It was at Ottawa, at Government House, that we first learned how widespread is the love of nature among Canadians. Her Excellency Lady Grey not only showed us how interested she herself is in horticulture, but directed our attention to the fact that Canada is developing its horticulture side by side with

ward, for he recognises that the men and women of Canada possess the same love of nature that characterises ourselves. Nowhere is this indicated more strikingly than in the great establishment of the Dale Nurseries, which is situated at Brampton, in the heart of the country, not far from Toronto, and, of course, near the railway. Chancing to hear of the fame of the Dale Nurseries, we broke our journey from Guelph to Toronto and made our way thither. The town or village—memory refuses to say which—is pleasing. The houses lie separate from one another, each house surrounded by its unenclosed garden, with no jealous fences to denote the several limits of the gardens. A short walk brings us in sight of an extensive range of glasshouses. Line after line the houses extend, well built and in perfect order; and, indeed, they may

FIG. 78.—FORCING LILY OF THE VALLEY AT THE DALE NURSERIES, CANADA.

the major industries of farming and fruit-growing.

As for the spaces which lie between the towns—flat, illimitable—they seem at first to have nothing to show but enormous farms, with Maples skirting the railroad and scattered Cratægus or burned stumps thereof marking a clearing. It is in this respect, however, that the visitor, if he has the leisure, may learn to correct his first impressions and to come to realise that the Canada of to-day does not consist of a rough sketch or outline of an established country, bent only on the pursuit of the essential, basic industries, but that it is, though still the land of vast opportunity, already occupied with the no less essential amenities of life. Outlying from the great cities, the traveller may find beautiful country houses, with finely-planned and tended gardens. Seeing them, his thoughts return swiftly home-

well be extensive, for from them go out the Roses and Carnations which supply the whole Dominion, or at all events reach to the uttermost parts of it. Consignments of these and other flowers are sent regularly as far as Newfoundland on the one side and Vancouver on the other. In times of glut the flowers of the Dale Nurseries invade New York itself, though for tariff and other reasons that market is not—as we gathered—favoured at other times. The distribution of cut-flowers over such great distances has compelled the adoption of the most-careful methods for preparing the flowers for transport. The method found most successful is to bring the Carnations, Roses, &c., into a cool room and to keep them for one to two days in a temperature of about 52° F., or as much below 60° F. as can be managed conveniently.

Of the varieties of Roses grown, the

Bride (white-cream), Bridesmaid (pink), and Richmond (good red) are the chief. The blooms are graded in three series, according to length of stem. The Carnations which command the best sale are Mrs. Thomas W. Lawson (dark pink), White Lawson, White Enchantress, and Harlowarden (crimson). As is so often the case, the producer is compelled to share his profits liberally with the retailer, and we learned that the price obtained at the Dale Nurseries for Roses at the time of our visit was 2½ cents., whereas the price in the shop at Toronto was 50 cents. Nevertheless, the general air of prosperity of the establishment is evidence that the business of flower-growing, when conducted on such sound lines as are there displayed, is by no means unprofitable, and also justifies our previous statement that the love of flowers is as widespread among Canadian members of the Empire as it is among those who live in the old country. This is demonstrated further by the remarkable development which the Dale Nurseries have undergone during the past few years. Some 12 years ago, when Mr. Harry Dale, the founder of the nurseries, died, they were entrusted to two executors, Mr. J. W. Duggan and Mr. W. Algie. From a comparatively small state the nurseries have developed, till now they claim to be the largest for cut-flowers in the American continent and indeed in the whole world. The 3½ acres of glass have grown to 20 acres, and further additions are in progress.

Mr. Algie, whom we had the pleasure of meeting at Brampton, attributes, modestly, the major part of this success to Mr. Duggan. Both gentlemen are of British descent, Mr. Duggan being an Irish Canadian, born and bred, however, in the Dominion, and Mr. Algie proudly and humorously boasting descent from a Scotch Covenanter, who was hanged by Claverhouse, and whose faithfulness to his creed is commemorated in the Martyrs' Monument at Paisley.

Mr. Algie is the typical Canadian—alert, strenuous, and cultivated, displaying his ancestry, however, in a passion for the poems of Burns, a delight in rendering them in their native Doric, and a belief in the value of a good education.

Though Carnations and Roses loom largest in the Dale Nurseries, other plants are grown on an extensive scale, and a considerable trade is done in the distribution of plants (*Ampelopsis Veitchii*, which

is hardy in that part of Canada) and cuttings—for instance of Carnations, which are sent out in thin paper "pots"—five per pot—as far afield as the Rockies. Adiantum is grown largely and also Lily of the Valley. Orchids, which are comparatively a new venture, are now being cultivated on a large scale. They are accommodated in four houses, each 115 feet by 25 feet, and four more houses are about to be built. The cultivation in this depart-

giving the choicer blooms. The plants are at their best during Christmas time, and in Christmas week no fewer than 66,000 blooms are disposed of. The plants are discarded annually about July. The culture is in benches, the same soil often being used for several years, though a top-dressing of a few inches of mixed soil and manure is usually added. Phosphatic manures are not applied, but the soil receives a dressing of lime when the plants

FIG. 80.—INTERIOR OF ROSE HOUSE AT THE DALE NURSERIES, CANADA.

ment is under the charge of Mr. W. J. Jones, who was till recently Orchid grower to Messrs. Hooley Bros., Southampton, England. The Orchid cultivation was started eight years ago by a Dutchman, who was originally engaged to grow Lily of the Valley on a commercial scale. The Orchids grown at the Dale Nurseries include *Cattleya Mendelii*, *Laelia purpurata* and *L. majus*. At the time of our visit, a large collection of South American (Columbian) Orchids had just been received, including 1,500 plants of *Cattleya Schröderæ*, *C. gigas*, and *C. Skinneri*, 1,000 *Lycastes*, and 2,000 *Cattleya Trianae*.

With respect to methods of cultivation: in the case of Carnations, cuttings are taken in spring, and half are grown under glass and half out-of-doors, the former

are about a foot high. The Carnations are trained to strained wires in three tiers, and the rows are supported by three tiers of strings attached at right-angles to the wires. Even at the late period of the year at which our visit was made, the Carnation houses presented a splendid sight and the plants appeared to be absolutely free from rust, which disease we have seen rampant in other places in Canada.

The Roses are also grown planted out in cement benches. The benches are each about 1 foot deep. At the bottom of the bench, clay is put to 10 inches from the top, and then at intervals and running longitudinally tile drains are placed. The bench is filled in with 3 inches of cinder over the drains and then 5 inches of soil. The houses are steam-heated, the

FIG. 79.—THE PLANT HOUSES AT THE DALE NURSERIES, CANADA.

pipes running along the top. The Roses, which are grown on the Manetti stock, are cut back moderately from May onward to provide successional blooms, and serve for about six years. The plants do not get a complete rest, but the soil is allowed to become somewhat dry at the "resting period." The head of the indoor department was emphatic on the necessity for the adoption of special methods for Canadian conditions, and complained, though not unkindly, of the conservative instincts of British gardeners. The criticism is perhaps not altogether unfounded, but we gathered the impression that it applied rather to detail than to general practice. That our view would appear to be correct follows also from the fact that we had, during our visit to Canada and the States, a fair number of opportunities of inspecting some of the best gardens, and were satisfied that the British gardener, when translated to America, is able to hold his own with credit and distinction against all others. Nevertheless, it is well to be reminded by friendly critics of our defects, and a general impression which we received was that the Briton is less resourceful than the "American." We are inclined to trace this less to national defect than to our methods of education, which are apt to be too bookish and too much divorced from practical realities. In any case, our visit to the Dale Nurseries was not less pleasant than instructive, and we found therein a rare combination of shrewd business capacity and high skill in cultivation.

THE JOHN INNES HORTICULTURAL INSTITUTION.

REPORT ON THE WORK OF THE INSTITUTION IN 1910.

FIVE acres of land were acquired in March, and have been laid out in plots. Sheltering fences have been planted.

Three span-roof glass-houses, with a corridor, have been built by Messrs. Mackenzie & Moncur, all the woodwork being teak. The eastern house is the largest, having side and centre staging. The next house is fitted along one side with breeding cages, enclosed in brass gauze, and with a glazed compartment for fumigation. The western house is a stove, with a plunging pit for propagations.

Each house has an adjustable work-table, on which plants of various heights can be conveniently examined.

A laboratory, potting-shed, boiler-house, mess-room, and offices have been built. The laboratory consists of two chief rooms, the one for chemical, the other for general biological work. Between the two are lavatories and a small private room containing piers for a balance. In the roof a photographic room has been enclosed.

Besides the newly-erected glass-houses, three of the houses in the Director's garden will be available for the work of the Institution. Of these, one has been altered somewhat so as to serve for a small orchard-house.

The glass-houses are in working order, but the fittings for the laboratory are not quite finished.

Mr. E. J. Allard, of the Cambridge Botanic Garden, has been appointed superintendent.

Regulations for exhibitors have been prepared, and candidates will shortly be invited to apply.

The work done in this, the first year of the Institution's existence, has necessarily been pre-

liminary in character. Besides the Director, the following have taken part in the work of the Institution, or used the facilities provided:—Mr. W. O. Backhouse, who has been appointed to a studentship, Miss D. M. Cayley, Miss F. M. Durham, Miss B. Gray, Mr. R. P. Gregory, Miss D. Marryat, Mr. G. P. Mudge, Miss C. Pellew, who holds a minor studentship, and Mr. C. W. Richardson.

A studentship was also offered to Miss M. Wheldale, Fellow of Newnham College, Cambridge, who is engaged in research in the chemistry of colour in plants, but she decided that, before undertaking work at the Institution, it would be well for her to go through a special course of training in certain practical methods.

Of the subjects studied, the following may be mentioned:—

Further investigations in the heredity of culinary Peas, especially in regard to the peculiar phenomena first noticed by M. P. de Vilmorin in the "Acacia" varieties.

Mr. C. W. Richardson has made extensive experiments in breeding Strawberries, a subject full of both scientific and economic possibilities, and he has brought to the Institution a large collection of types, with a series of cross-breeds previously made by him.

A small collection of Begonias has been made with a view to hybridisation, and investigation of various problems in this genus. Of these, the inheritance of double flowers, and the extraordinary developments in *Begonia phyllomanica* have been especially the subject of experiment.

The genus *Campanula* has also been chosen as a subject of special study, and various experiments have been made with its species.

The experiments on *Mirabilis*, hitherto conducted by Miss Marryat, at Cambridge, have been transferred to the Institution. (This work was described in *Rep. Evol. Ctee. Roy. Soc.*, V.)

Some sample cultivations of Sugar Beets have been made, and if the subject is found a promising one, it is proposed to make a continued series of experiments with these plants. The relation of annual to biennial varieties is a subject of much scientific interest, and also of great economical importance, inasmuch as serious loss is suffered in certain cases by running to seed of root and other crops. There is no reason, *a priori*, why, by the application of proper genetic analysis, this loss may not be prevented. Certain other possibilities of amelioration of the types are also being considered.

A collection of seeds of varieties of Cabbages possessing peculiarities of habit has been presented by Messrs. Sutton & Sons. These will be used in an investigation of the properties of biennials, the work being cognate with that contemplated in regard to Beets.

The glass-houses are being largely used this winter for the families of *Primula sinensis*, which have for several years formed the subject of Mr. R. P. Gregory's researches. The nature of the work will be best understood by reference to Mr. Gregory's paper (now in the press), which will appear in Part II. of the *Journal of Genetics*.

The *Primulas* will be succeeded by a collection of *Capsicums*, which, it is anticipated, will provide subjects for a variety of inquiries.

A crop of *Petunias*, upon which Mr. Mudge has been engaged, was accommodated during the summer.

A small representative collection of fruit trees has been bought and planted. These will be used in breeding and other experiments to be conducted by Mr. Backhouse, and in certain experiments which Miss Cayley is instituting in regard to fungoid pests, especially fruit-rot.

The Institution is indebted to Messrs. Laxton Bros., of Bedford, for a number of cross-bred plants and fruit trees raised by them, which have already reached maturity.

Various material of interest which had resulted from work previously done by Mr. Backhouse, at Cambridge, has been installed at the Institution.

Besides the subjects named above, preliminary trials have been made with plants of several Orders.

One cause of anxiety should be mentioned. Of the experimental Peas, a considerable number, after making good growth, succumbed to a disease of obscure nature, and almost all Sweet Peas (which had been sown as a trial of the capabilities of the soil) died in the same way. Various suggestions as to the nature of this

disease were made, but none seemed to apply. From inquiry, it seems that the affection is common in the district. Hopes are entertained that a dressing of lime which has been applied may do good. If this difficulty cannot be obviated in the future, one of the most fruitful subjects of work may have to be given up.

Leave of the Charity Commission has been obtained for the installation of experiments relating to animals, in so far as they are ancillary to the horticultural investigations. The families of canaries, which have formed the subject of Miss Durham's researches, are already in an out-building of the Director's house. Certain strains of poultry are about to be transferred from Cambridge. The main object of both these sets of investigations is to throw light on the problem of the nature of sex, a fundamental requirement in all genetic research. With the same object, material for experiments on Bees is shortly to be obtained.

It is clear that if the work already in progress and in contemplation is to be adequately carried out, an extension of the acreage must be made before long. Probably this can best be done by renting land adjoining the Institution.

The Institution is much indebted to the following persons and institutions for material presented:—The Royal Gardens, Kew; the Royal Botanic Garden, Edinburgh; the Royal Botanic Garden, Glasnevin; the University Botanic Garden, Cambridge; the Physic Garden, Chelsea; the Arnold Arboretum, Brookline, Mass.; Messrs. Vilmorin-Andrieux et Cie., Paris; Messrs. Laxton Bros., Bedford; Messrs. Sutton & Sons, Reading; Messrs. Banyard & Son, Maidstone; Messrs. Veitch & Sons, Chelsea; Messrs. Desfossé Thullier Fils et Cie., Orleans; Mr. A. A. Pettigrew, Bedford; Mr. A. Bliss, Tunbridge Wells. *W. Bateson, Director.*

NOTICES OF BOOKS.

CALIFORNIAN FLORA.*

So many garden plants come from California, that works dealing critically with the flora of that country are always welcome. The issue of the present edition has been considerably hastened by reason of the destruction of the supply of the first edition in the San Francisco disaster of 1906. It is a descriptive account of the native and naturalised flowering plants growing in the region about San Francisco Bay, east to the Sacramento and San Joaquin rivers, north to the south line of the counties of Mendocino, Lake and Colusa, and south to the Pajaro River and Pacheco Pass.

Most diverse views are held by botanists regarding some of the Californian genera of plants. Take, for instance, *Eschscholtzia*. Dr. Fedde has recently monographed this genus in Engler's *Pflanzen Fauna*, and has retained 123 species as distinct. But Dr. Jepson, for his region, retains only three. But under *E. californica*, (Cham.), the California Poppy, he states: "this species is highly variable, especially so in trivial details of leaf segmentation and of shape of calyptra, and in habit, and so runs into a vast concourse of forms. A large number of these forms have been collected, but perhaps not one-tenth, or even less of those in existence. Yet the number of specimens distributed to herbaria has been sufficient to form the basis for nearly 100 proposed new species published by Eastern and European systematists within a very few years." Dr. Jepson has nine species of *Calochortus* in his flora. He divides these into three sections in his clavis: (a) the Mariposa Lilies; (b) the Star Tulips; and (c) the Globe Tulips. In *Brodiaea* he has 11 species—these again are divided into three sections: (a) *Hookeria*; (b) *Dichelostemma*; (c) *Triteleia*. The most distinctive and sharply defined feature of the region of this flora is the Redwood belt. Associated with the Redwood are the Tan Oak, Madrona and Douglas Fir. Outside the Redwood belt is a beach strip characterised by such shore plants as *Abronia latifolia*

* *A Flora of Western Middle California*, by Willis Linn Jepson, Ph.D. (Cunningham, Curtis and Welch, San Francisco.) Svo. Second edition, 1911.

and *umbellata*, *Lathyrus littoralis*, *Mesembryanthemum aquilaterale*, &c. The coast ranges of the region are characterised by barren slopes or hills, by slopes openly wooded with Oaks, or by chaparral, the latter being the most marked feature. The term chaparral refers to the extensive and dense colonies of shrubs which clothe mountain slopes and ridges, and includes such typical species as *Ceanothus cuneatus*, *Arctostaphylos manzanita* and *tomentosa*, *Pickeringia montana*, &c. Some of the species most abundant in individuals and, consequently, in wide areas, the dominating species of the vernal flora, are as follow:—*Avena fatua*, *Danthonia californica*, *Phacelia distans*, *Brodiaea capitata*, and varieties of *Mimulus Langsdorffi*.

In relation to local species, the region immediately north and south of the bay has some interest in plant geography. *Campanula exigua* is found only on the summits of Mt. Diablo, Mt. Tamalpais and Mt. Hamilton; *Calochortus pulchellus* is local about Mt. Diablo, and *Streptanthus hispidus* in the inner south-west range. In this connection may be mentioned the genus *Ceanothus*, represented by 14 species in the Bay Region, of which eight are nearly, or quite, restricted to the Central Coast Ranges.

The extensive plains of the Great Valley, the Sacramento and San Joaquin are level and treeless, save for Oak groves on restricted areas mainly along streams, or for a fringe of trees bordering the rivers. Alkaline areas of the plains, whether very limited spots or extensive plains, have their own peculiar species. The most abundant and widely-distributed being *Distichlis spicata*, *Atriplex bracteosa*, *Sida hederacea*, and *Cressa cretica*. The fall flora of the valley plains is represented by great colonies of a comparatively few species. The most important are *Erenocarpus setigerus*, *Grindelia camporum*, and more especially the so-called tarweeds such as *Hemizonia luzulaefolia virgata* and *Keeloggii*. The first edition of this work was published in 1901. In the second edition, as in the previous work, there is a key to the species under each of the genera, and a description of each species. And the only real fault we have to find is that the type in which this key is printed is rather too small. As has already been pointed out, Dr. Jepson, in certain cases, seems to take an aggregate rather than a segregate view of the species with which he deals, but he has long been known in this country as a most careful and critical worker, and we can confidently recommend this little book as a trustworthy guide to the plants of Western Middle California. *E. G. Baker.*

ORCHID NOTES AND GLEANINGS.

CYMBIDIUM GOTTIANUM.

THIS choice hybrid *Cymbidium* was raised from *C. chameum* and *C. insigne Sanderi*. The plant was exhibited at the meeting of the Royal Horticultural Society on March 14 by the raisers, Messrs. Sander & Sons, when it was given an Award of Merit by the Orchid Committee. The flower has special claims to beauty in its handsome white segments with a faint green tint on each of the sepals. The handsome lip is blotched with ruby-purple, and there are markings of the same colour on the side lobes.

BRASSO-CATTLEYA VILMORINIANA.

WITH respect to the note on p. 146, I may say that Messrs. Pauwels et Cie. are quite wrong in claiming the priority for this hybrid, for my firm showed at the meeting at Brussels on March 20, 1910, the same hybrid under the name of *Brasso-Cattleya Elegance*. Since my last presentation, I asked the President of the Brussels Society to rectify this name and consider my exhibited name as *Brasso-Cattleya Vilmoriniana* var. *Elegance*. *Ch. Maron, Brunoy.*

NOTES ON IRISES.

SPECIES AND VARIETIES OF IRISES.

No botanical question is more difficult to answer than this: What is a species, and what is merely a variety? The examination of any large collection of living plants or of herbarium specimens shows that when analysed in detail scarcely any two plants are absolutely identical, and the botanist's difficulty lies in discriminating between essential and non-essential differences and similarities. Moreover, for the botanist, as opposed to the gardener, the difficulty is rendered the more insuperable by the fact that its solution is probably not to be found in herbaria at all, but must be sought in the evidence of seedlings. In these days, when gardening is so popular, it is astonishing that few can be found to engage in the fascinating pursuit of raising supposed species from seed, and of noting the variations in the resulting plants. It is curious, too, that this is not a method of inquiry that seems to appeal to the professional botanist. At any rate, it is rare

this, it was surprising to find several variations among self-sown seedlings of a plant of this Iris, which came originally from the River Wey in this immediate neighbourhood. The parent plant bore flowers of a deep yellow, with a distinct patch of dark veining on the falls, but, among the seedlings, there was a paler yellow form, with no trace of these markings. Moreover, the precise shape and dimensions of the standards were different in nearly every case.

Take, again, another familiar species, *I. reticulata*. In the wild state, apparently, the deep, blue-violet form, which is known to botanists as the type, is much rarer than red-purple forms, to which the name of *I. Krelagei* has been given. Moreover, among plants raised from self-fertilised seed of the so-called type, the type itself is probably the rarest form to be obtained. What is more remarkable still is that, though this evidence would seem to point to the fact that we have here two varieties of the same Iris, the capsules of the two forms are quite distinct in shape. That of the blue form, the so-called type, is long

FIG. 51.—CYMBIDIUM GOTTIANUM: FLOWERS WHITE, LIP BLOTCHED WITH RUBY-PURPLE COLOUR.

(Received R.H.S. Award of Merit on March 14.)

to find any that put it into practice, or any provision for it at large botanical institutions.

It may be that monocotyledons—and Irises in particular—are more liable to vary than other plants, and the object of this note is to give instances from this genus, in the hope that it may elicit information from those who have closely studied other genera.

Let us take first an Iris with which everyone is familiar, namely, *I. Pseudacorns*, the yellow water Iris that is common in England and all over Europe. Several varieties of this Iris have received specific names, such as *I. Bastardii* and *I. acoriformis* (*Bor. Fl. cent. France*, Ed. III., p. 635, 1857), *I. curtropetala* (*Redouté Lil.*, t. 340, 1812), and *I. acoroides* (*Spach Hist. Vég.*, XIII., p. 44, 1846). These species were based on variations in colour, in the length and shape of the standards, and on the presence or absence of a darkly-veined patch on the blade of the falls. It is true, of course, that they have ceased to be looked upon as species, but they are still kept up as something more than mere garden varieties in the latest work on the European flora. In face of

and narrow, and that of *Krelagei* short and broad. When compared with the capsules of a number of other Iris species, these two are seen at once to resemble each other; but, on the other hand, it would be easy to separate a mixed collection of capsules of these two forms into two distinct groups.

Another instance is supplied by the case of *I. graminea* and its broad-leaved form, on which the specific name of *I. sylvatica* was bestowed by Balbis (*Room. and Schult. Syst.*, I., 476). The form of *I. graminea* most commonly found in nature and consequently in herbaria, and also in gardens, has narrow, grassy leaves, scarcely more than $\frac{1}{4}$ inch to $\frac{1}{2}$ inch broad, and not much more than 15 to 18 inches long. When, however, seedlings of this Iris are raised and grown from the first in good soil, there is a remarkable change. In the majority of cases, the leaves are much longer and wider, and frequently attain to 3 feet in length, and over an inch in width, so that the plants are scarcely recognisable.

A slightly different question of classification was settled by the raising of *I. Albertii* from

seed. This was originally classed among the *Pseudevansia* group, in which were placed those Irises in which the beard appeared to rise from a more or less distinctly-raised ridge or crest. The seedlings showed that this supposed ridge is not characteristic of the species, and is, indeed, often entirely absent. Further evidence of the worthlessness of this character was supplied by the examination of numbers of seedlings of *I. Chamæiris*, and other dwarf Irises, which commonly usurp the name of the true *I. pumila*—a plant which is, apparently, exceedingly rare in our gardens. Many of these seedlings showed signs of a crest beyond the end of the beard, but the amount varied even on the three falls of the same flower. The first specimen found by Regel, in Turkestan, probably had distinct traces of crest, but, in other respects, *I. Albertii* is nothing but an ordinary bearded Iris, and should appear among the *Pogoniris*, in the company, perhaps, of *I. obtusifolia* and *I. Talischii*, which it resembles in some respects, especially in the case of a yellow-flowered form which has appeared among the seedlings.

The instances given above have tended rather to help than to perplex the puzzled inquirer. Other results, however, also obtained from seedlings, have only increased the difficulty of the subject. Perhaps the most astonishing result was the discovery that the white-flowered form of *I. tectorum* comes invariably true from seed, although no character except colour can be found to separate it from the blue-purple type. Moreover, the pollen of the white form has no effect on the blue when the two are crossed, at any rate, in the first generation, for nothing but blue-flowered forms have resulted from this cross. The Mendelian theory suggests the raising of a second generation, but, unfortunately, first crosses among Irises are often sterile, unless the parents are closely allied. Thus *obliensis* × *Korolkowii* and *Cengialtii* Loppio × *tectorum* have both proved infertile, and the whole experiment points to the fact that the so-called white *I. tectorum* is, perhaps, something more than a mere colour variety.

Another puzzle lies in the various forms of *I. setosa* and *I. Hookeri*, the Asiatic and American forms of what appears to be the same Iris. In these, the standards are reduced to minute bristles, or, at any rate, to very small dimensions. The exact form of the standards does not appear to be constant, nor do either of the two more usual formations appear to be correlated to any other character. At least four or five distinct forms of this puzzling species come sufficiently true from seed for groups of them to be at once distinguishable, though the exact differences are very difficult to define.

The same difficulty occurs in the case of the various forms of *I. ensata*, of which name the synonyms are legion. The leaves of a batch of a dozen or twenty plants of one form all grow with a curious twist, which is noticeably absent from those of a neighbouring group. Yet dried, herbarium specimens would appear essentially alike.

Another unsolved problem is that of the group of American Irises to which the names of *I. longipetala*, *Herbert*, *I. missouriensis*, *Nuttall*, and *I. tolmeiana*, *Herbert*, have been given. An examination of the type specimens of these three species seems to suggest that the two latter are identical, and that they represent the Alpine or dry upland form, while *I. longipetala* is the more luxuriant Pacific Coast variety. The latter has broader, longer leaves, and a sturdier and fuller inflorescence. Moreover, the new leaves come up in the autumn, and attain some height during the winter. All these characters are reproduced in seedlings, as is also the case with the more slender form to which the other two names were given. Here the leaves do not shoot until the spring, and never attain the height or luxuriance of those of *I. longipetala*. The flowers, however, and the essential organs of the two forms are identical, except, perhaps, in size. (No ac-

count is here taken of what is, perhaps, an unnamed species, often found in gardens under the name of *I. missouriensis* or *I. tolmeiana*. This has in the spathe only two flowers, in which the ovaries are nearly sessile, while the pedicels of both the forms of *I. longipetala* are produced to some length, and the number of flowers in the spathe nearly always exceeds two.)

On the whole, these instances tend to show that plants are very like human beings, among whom family likenesses are transmitted from generation to generation. Yet no one will deny that family likeness is much more marked in some families than in others, though no reason has ever yet been given for this phenomenon. Individual differences are always found, even when the family resemblance is most strong, and this consideration would seem to point to the extension rather than to the narrowing of the limits of each species. *W. R. Dykes, Charterhouse, Godalming.*

DISEASE-RESISTING POTATOS.

It is well known that determined efforts are at present being made in order to secure, if possible, a strain of Potatos immune from disease. The labours of Mr. Arthur Sutton and the Rev. J. Nikman Paton in this field of botanical science are noteworthy and deserve the highest commendation. It is to be observed that the efforts of these workers have been concentrated upon certain species of *Solanum*, and two kinds, viz., *Solanum Commersonii* and *S. tuberosum* seem to be in particular request as parental subjects. For 12 years I have been engaged in a somewhat similar work, the aim being to secure an immune strain of Potatos, but I have refrained from using these species of *Solanum*, and have confined my attention to an immune variety of the domestic Potato. Incidentally, with respect to Dr. Salaman's work in Potato-breeding, recently summarised in these pages, it may be remarked that my experience with respect to correlation between sterility of anthers and pale heliotrope flowers does not conform with this. I have met with one or two varieties with flowers of this description which have perfectly normal anthers, but, while I have bred from these sorts, I find I have retained no records of their progeny.

Some years ago I spent a considerable time in looking for a suitable variety of *S. tuberosum* that could be used with advantage as a parent in breeding for immunity from the disease of late blight (*Phytophthora infestans*). I was not inclined, as I have said, to accept any of the species of *Solanum* for this purpose, for at that time I was very doubtful as to their edible qualities and preferred a cultivated variety possessing the attribute of immunity, coupled, if possible, with that of quality. Ten years ago I secured a Potato in the North of Scotland which had been in the hands of a well-known family there since 1745, and was said never to have been attacked by disease. This statement I have confirmed, for, although it has been grown by me continuously, I have never noticed in it the slightest trace of disease. This old Potato was submitted to some pretty severe tests, and one season, during which blight was unusually severe, the diseased haulm and tubers of affected Potatos were allowed to rot on the ground where they had grown. When sufficiently decayed, they were all dug into the ground, which, therefore, must have been full of the hybernating mycelium of the fungus. This piece of ground so treated was planted up in spring with several well-known commercial varieties of Potatos, and a good row of the old, supposed disease resister. All save the latter were badly affected, so much so that the tubers were worthless. This old variety was grown for three seasons more upon the same ground, and still proved invulnerable. It is of splendid edible quality, but the colour of its tubers, combined with its poor cropping powers, render it useless for ordinary commercial pur-

poses. Its great value lies in its power to resist disease, and I am now engaged in the endeavour to effect the transmission of this virtue to well-known standard varieties. I had, however, nearly discarded this old worthy as an unworkable proposition, because of its sterility. Last year, however, it yielded pollen. During a period of 10 years it was sterile to all pollen from other Potatos, and also, this season, it proved sterile to its own. I have been able to secure crosses between it and some excellent subjects, having used successfully "The Factor" and "The Admiral" as seed-parents. I have secured an abundance of fertile seed, and shall therefore be in a position presently to determine whether any of the crosses combine disease-resistance with other essential qualities. I had not intended to publish my results till I was in a position to describe the qualities of my first generation hybrids, but in discussing the incidence of disease in Potatos in the *Journal of Genetics*, Dr. Salaman remarks, that up till now the fact that there has been no really immune variety to work with has prevented any headway being made in this direction. This is a statement that, obviously, I am not prepared to accept, until the variety, which I have tested for 10 years is proved to be liable to an attack of disease. I will defer a description of my immune variety until I have completed my investigations as to its origin, but this is certain, that during 10 years' observation in England and Scotland, and in many different districts in the latter country, under severe conditions, it has so far proved immune. The question now is, will this character be transmitted to the seedlings of which it is one of the parents? *George M. Taylor, Mid-Lothian.*

CULTURAL MEMORANDA.

LACHENALIAS.

LACHENALIAS cannot be classed among the most brilliant of flowers, but they possess a beauty of form and delicacy of colouring which make them attractive, especially at this time of the year, and the blooms last in a good condition for at least a month. The plants are easy of culture. To have them in bloom early in the year, the first batch of bulbs should be potted early in July and others at intervals of a fortnight till the middle of August. A suitable compost is formed of two parts loam and one of leaf-soil or well-rotted manure, with a light dusting of soot and some coarse sand added. Five-inch pots are the most suitable receptacles; they should be well drained, and filled three-parts with soil. Place six or eight bulbs in each pot half-an-inch below the surface, pressing the soil firm with the fingers. Water the soil carefully, and stand the pots in a frame that must be shaded from sunshine, but expose the plants to the light when the growths appear through the soil. Continue to afford water with care until the pots are filled with roots, when they should be given copious supplies of moisture, and soot water or a little fertilizer twice a week. Before there is any danger from frost, place the plants on a shelf close to the glass in a greenhouse where a temperature of 40° is maintained at night time. Lachenalias will not submit to excessive forcing; they require an abundance of fresh air during mild weather, but are susceptible to cold draughts. The plants need attention after flowering: as the foliage turns yellow, lessen the supply of water gradually. When the foliage is dead, place the pots on their sides in a dry place, and leave them till the time comes for shaking the soil from the bulbs and repotting them. Lachenalia *Nelsonii* is much the best sort for early flowering; the golden-yellow flowers have light green markings and the inflorescences attain to a height of from 12 to 15 inches; *L. pendula* has purple, red and yellow flowers and grows to a height of 9 inches; whilst *L. tricolor* produces bright green, red and yellow flowers. *J. R., Enfield.*

The Week's Work.

THE FLOWER GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of Haddington, K.T., Tynninghaue, East Lothian.

SHRUBS.—The protective coverings may now be removed from tender shrubs, the shrubs themselves examined and the dead growths cut out. Those trained to walls will need to be re-fastened. Any which have flowered recently, such as *Lonicera Standishii* and *Jasminum nudiflorum* should be pruned and secured to the walls; if extra long flowering shoots are desired, the plants should be pruned every second year only.

NARCISSUS.—The forced bulbs of *Narcissus*, after they have flowered, are as valuable for planting in grassy spots as the cheaper bulbs offered every autumn. They are useful also for planting rather widely apart amongst herbaceous plants in the mixed borders, where they serve to produce a bright effect at this season of the year without interfering with the subsequent display from the summer-flowering plants. Nevertheless, certain varieties are rather fastidious as to soil; such, for instance, as *telamoniensis plenus*, *maximus Sulphur Queen*, *Princeps*, and *Golden Spur* in our own case. Other varieties succeed more easily, and such fine sorts as *Mme. Plomp*, *Victoria*, and *Sir Watkin* have infinitely finer qualities than many of the older varieties which many gardeners are content to plant. Forced *Narcissi* are generally planted out at about this time; some plant them whole, but others divide the bulbs and arrange them singly or in twos or threes. The implement used for planting is a spade, with which a notch is made in the ground, and, by a forward pressure, sufficient space is secured to permit one or more bulbs with their roots to be placed in the soil. The spade is then withdrawn and the soil pressed close back with the foot. Forced *Crocuses* and *Tulips* may be planted at the same time.

CLIPPED SHRUBS.—If there is sufficient labour to allow the examples of topiary to be trimmed, this work should now be done. At the very least, the variegated plants should be trimmed, and any specimens which have got a little out of shape restored with rather closer pruning than usual. Hedges of variegated *Yews* should be clipped mainly for the reason that the young growths which will soon follow the clipping keep a very bright colour throughout the season, whereas if they are cut in the autumn they remain partly green for several months. *Cupressus sempervirens*, at one time a common-enough object, is now rarely seen in gardens, yet it has no equal as a pyramid. It may be trimmed almost as regular as a *Yew*, but the cutting should be rather less severe.

CALCEOLARIA.—The less tender sorts of *Calceolaria* succeed perfectly when planted out direct from the frame in which they have been rooted into their permanent positions in the flower garden. If they are planted amongst *Tulips* or other spring-beding plants, they need no further attention, as these latter plants provide a certain amount of protection for the *Calceolarias*. Tall-growing *Lobelias* are also hardy enough to be planted out at any convenient time after the present date. *Pelargoniums* and most other bedding plants may now be safely removed from the glass structures and pits to unheated frames, or even temporary frames, where the lights can be covered for a time both by night and day until the plants are gradually inured to exposure to the weather. Cold winds are as harmful as spring frosts, and the plants need protection from them.

GRASSES.—A few ornamental grasses may well be allowed a place in the pleasure garden besides the ubiquitous *Pampas Grass* and *Arundo Donax*. Such species as are raised from seed should be sown now, either where they are to remain, or in lines, if they are intended for transplanting later. *Setaria macrochaeta* rises to a height of 3 or 4 feet and is very effective. Dwarf-growing grasses may be represented by *Eragrostis elegans*, *Briza maxima* and *Lagurus ovatus*. The

variegated *Maize* must be raised under glass, placing each seed in a 3-inch pot and repotting the plants until they are large enough to plant out. Of perennial grasses, the commonest are the variegated forms of *Dactylis glomerata*; I have also used sparingly *Festuca glauca* and *Isolepis gracilis*. *Stipa pennata* is useful, whilst *Digraphis arundinacea*, with striped leaves, is one of the very best kinds. Established plants of the latter species need to have the flowering stems removed twice during summer. The best results are obtained from very small offsets taken at the present time; these will not give any trouble through flowering.

PLANTS UNDER GLASS.

By JAMES HUDSON, Gardener to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, Middlesex.

EXACUM MACRANTHUM.—Any plants of *E. macranthum* which have been wintered in small pots, either as cuttings or seedlings, may now be given a shift into pots not more than one size larger than those which already contain them. A light, fibrous loam is better than peat for this species. After the plants have been potted, place them upon a shelf and water them sparingly. It may be possible to obtain a few cuttings from the larger plants, but these should be selected from the lateral growths near the base of the stem, rejecting the strong, sappy shoots. The cuttings may be rooted in thumb pots placed in a moderate heat under a bell glass, the bell-glass being used to prevent flagging.

CODIÆUM (CROTON).—Such *Crotons* as are needed for decorative purposes outside the stove need to be well prepared to withstand the cooler temperatures to which they will be subjected. The present time is suitable for examining the stock of these plants, in order to afford a top-dressing to some, and to move into larger pots others which require increased rooting medium. In cases where top-dressing alone is carried out, attention must be directed to the drainage, which should be put into perfect condition. Remove any sour, inert soil. The new compost applied in the top-dressing must be pressed very firmly. In repotting *Crotons*, it is usually best to employ pots only one size larger than those already containing the plants. The potting must be done firmly, because it is desirable to promote sturdy, short-jointed growth. In the case of large specimens, a reduction of the root ball and a corresponding pruning of the branches may be desirable. Where such treatment is carried out, pots of the same size will again suffice for the plants. *Crotons* require a stove temperature and full exposure to sunshine. Frequent syringings with clear water, preferably water which does not contain lime, have a good effect upon the plants and serve to keep them free from thrips and red spider. Bug, scale and mealy bug are troublesome pests, and the plants should be carefully examined before they are repotted, using a well-approved insecticide and hot water for the purpose of destroying any of these pests that are present. Cuttings may now be inserted for maintaining a supply of small decorative plants, selecting healthy, well-proportioned shoots bearing plenty of foliage, so that the leaves will be close down upon the soil if the cuttings are inserted into a thumb-pot. My practice is to take the cutting without any previous operation, such as ringing, to induce the base to callus, although ringing may be found useful if bottom heat is deficient. The old-fashioned handlight is a good protection for these cuttings, and if any of the latter are extra long two handlights can be placed one above the other. Provided there is sufficient bottom heat, the cuttings will fill their pots with roots in five or six weeks. In selecting the varieties for cultivation as decorative plants, it will be found that those with reddish-coloured leaves are the most enduring.

ALOCASIA.—As prominent stove plants *Alocasias* are very ornamental subjects. A metallic effect in dwelling houses during summer. *Alocasias* do not start into growth so readily as *Caladiums*, and to attempt to start them too early is detrimental. If propagation is necessary, the tubers should be started in quite small pots, one tuber in a pot, but if larger masses are required several strong tubers should be placed together, but not so closely as to cause overcrowding. For large specimens, pans

are more suitable than pots, as the plants do not require a great depth of soil. The compost should be made up of good peat-charcoal broken to the size of a nut and *Sphagnum* moss; the moss may also be used as a surface dressing. *Alocasias* thrive well when raised above the pot or pan, as is done in the potting of many *Orchids*. In regard to soil, an exception should be made in the case of *Alocasia macrorhiza variegata*, which thrives best in turfy loam, the aim being to develop at its best the white variegation which characterises this variety.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbunt, Gloucestershire.

THUNIA.—The *Thunias* are now starting into growth after having been dormant in a cool, airy house during the winter. When the young shoots are about 2 inches long they push forth roots freely from the base, and before this stage is reached the plants should be repotted. Annual repotting is necessary, and all old material should be shaken from the roots and the latter, being dead, must be cut away except for a short length, which is necessary to hold the bulbs firm in the compost. The plants are best made up into specimens, placing five bulbs in a 7-inch pot. Their requirements in respect to drainage and rooting compost are similar to *Calanthes*. Each plant should be secured to a neat stake, and the compost pressed moderately firm about it, finishing off about half-an-inch below the rim of the pot. Following this operation, water must be carefully afforded for a time, but frequent overhead syringing on fine days will encourage growths. *Thunias* enjoy a sunny position in the warmest house, and when in full growth abundance of water at the roots and frequent syringing of the foliage are needed. These plants may be propagated by taking off portions of the old pseudo-bulbs, cutting them into lengths, and inserting them as ordinary cuttings in pots of chopped moss, leaf-mould, and sand, or they may be laid on a bed of *Sphagnum*-moss. Place these cuttings in a warm propagating case, and when new growths are produced, pot them up singly and give every encouragement to them to grow.

PHAIUS.—This genus is one of the oldest representatives of the *Orchid* family in cultivation, and comprises useful plants, especially the spring-flowering species and hybrids, many of them thriving in structures devoted to the culture of ordinary stove plants quite as well as in the *Orchid* house. They are mostly of an ornamental habit, and good specimens bear fine foliage and large, erect racemes of flower. After the plants have ceased to flower, and the new growths are sufficiently advanced, any necessary repotting should receive attention. *Phaius* should be grown in fairly large, well-drained pots, in a substantial compost similar to that recommended for *Calanthes* in last week's *Calendar*. Keep the bottom of the plant beneath the level of the rim of the pot, and press the rooting material firm about the roots. During the growing season (summer) they delight in plenty of heat and moisture, and the roots need to be kept well supplied with water. They should be shaded from direct sunshine. After the season's growth is completed, the plants may be kept nearly dry in a cooler house, where a temperature of about 55° is maintained throughout the winter months. The foliage of *Phaius* is very subject to attacks from green fly, thrips, red spider, and scale. The plants, therefore, should be arranged so that the syringe can be freely used around them, both over and under the leaves in order to keep the plants clean.

PERISTERIA ELATA.—This plant needs similar treatment to *Phaius*, and specimens breaking into growth may need repotting.

TEMPERATURES.—Allow the heat of the houses to rise a few degrees above the figures given in *January*. With the lengthening days and increasing solar heat, the day temperatures will, in the warmer divisions, rise 10° to 15° on clear days. During such period the fires must be kept in check as much as the weather will allow, but a certain degree of warmth should always be kept in the hot-water pipes, so that the house may be properly ventilated by admitting fresh air.

THE HARDY FRUIT GARDEN.

By W. HEDLEY WARREN, Astor Clinton Gardens, Buckinghamshire.

COMPLETION OF PLANTING.—The planting of all kinds of fruit trees should be completed as quickly as possible. The ground is still in good working order, but as the main planting season is now past, the operation should be carried out with the greatest care, giving every encouragement to the trees, so that they may quickly establish themselves in their new quarters. Expose the roots as little as possible during planting operations, carefully cut away the bruised ends, and spread out the remaining roots as near to the surface of the ground as possible, or as may be considered safe. After planting, mulch the surface of the soil over the roots with a suitable dressing. Secure each tree to a strong stake, so that rough winds will not loosen its hold of the soil.

RASPBERRIES AND CURRANTS.—These or other bush fruits having an abundance of fibrous roots near the surface of the soil should be given a good mulching of half-decayed manure. On well-drained soils, the application of liquid manure at this time of the year to Raspberry plantations will prove of great benefit to the plants.

THE FRUIT BLOSSOM.—Continue to protect Peaches, Apricots, and Nectarines at night-time and during the day when cold winds or unfavourable weather prevail. Attend to the thinning of Apricots as soon as possible after the fruits have formed. Blossoms of Peaches and Nectarines on the underside of the branches nearest to the wall may be rubbed off, for not only are such misplaced blossoms useless, but their removal will aid in strengthening the remaining blossoms, which are generally far more numerous on these trees than necessary for an ordinary crop of fruit.

GRAFTING.—The choicer kinds of Pears and Plums may also require some temporary covering at night to protect the blossoms from frost. Continue the grafting of Pears, Apples, and Plums. Head back young or newly-planted trees, and, if the prevailing weather is dry, the latter will be benefited by receiving a good watering, especially if the soil is of a light nature or shallow.

BLACKBERRIES.—Wilson, Junr., The Mahdi, and the Loganberry are valuable either as dessert fruits or for the making of preserves. The culture of Blackberries is similar to that of Raspberries. Though the flavour of cultivated Blackberries is peculiar, it is one that is very generally liked. To be enjoyed in perfection, the fruit should be eaten when perfectly ripe and fresh, for the flavour deteriorates even in a few hours. Planted in rows of 6 or 8 feet apart, the growths may be trained in any desired direction, and being free and vigorous they quickly fill the available spaces. Each season, after the fruit has been gathered, remove all the old fruiting wood, and vigorously thin out the young growths, retaining those only that are required for fruit-bearing during the following season.

FRUITS UNDER GLASS.

By E. BECKETT, Gardener to the Hon. Vicary Gibbs, Aldenham House, Hertfordshire.

THE ORCHARD HOUSE.—As stated in an earlier Calendar, the orchard house should be maintained under conditions as natural as possible, and, whenever the weather permits, a free circulation of air should be allowed, admitting fresh air through both the top and bottom ventilators. Excepting when it is very cold, a little fresh air should be admitted through the top ventilators all night. When the various trees are in flower, syringing must be discontinued, and the flowers pollinated artificially. As soon as it is ascertained that the fruits have set, use the syringe again and damp the bare surfaces in the house twice daily. The thinning of the fruits should not be commenced too soon. If a very heavy crop of Peaches and Nectarines has set, some of the fruits may be removed, discarding first any badly-placed and deformed specimens. Apples, Pears, and Plums should be left for a while before thinning, as during their early stages many will drop. As soon as the growths lengthen, they should be pinched back, removing the shoots gradually, and those from the interior of the trees first. Water must still be given with care, avoiding an excess of moisture at the

roots. When the fruits commence to swell, the plants will be benefited by weak farmyard manure water, and by an occasional sprinkling of artificial manure on the surface of the soil. Keep a sharp look-out for aphid and thrips, and, should either of these pests be detected, fumigate the house with XL-All insecticide. Cherries especially are likely to become infested with aphid, and unless the insects are checked they will quickly spread over the young growths. As the shoots mature, use the syringe freely to prevent attacks of red spider.

CUCUMBERS.—The earliest Cucumbers should be growing away quite freely, and at this stage they will require attention at regular intervals, in respect to stopping and tying. Regulate the growths as evenly as possible, and stop them at two nodes beyond the fruit. Do not let the plants get overcrowded, but remove any growths which appear superfluous, and do not neglect to cut the fruits as soon as they attain a sufficient size, placing them in sufficient water to cover the stalks, until they are required for use. The plants being very active, the roots will need an abundance of water, and care must be exercised that they are not allowed to suffer for lack of this. An occasional application of diluted manure water will be beneficial, and, as cropping advances, applications of this stimulant may be made more frequently. When the roots can be seen above the compost a very slight top-dressing will be necessary. Cucumbers do not require a great amount of ventilation, but when the temperature in the house rises with sun heat to 80° or 90°, as is often the case in the middle of the day, just a little top ventilation will be beneficial. Very often Cucumbers are cultivated in the same house as Melons, the consequence being that more ventilation has to be allowed than the Cucumbers really need. Especially is this the case when the Melon fruits are ripening, but the effect of this excessive ventilation results in the Cucumbers being bitter, a defect which may also be brought about by dryness at the roots. Syringe the plants frequently with tepid water, and remove any leaves that show the least sign of red spider.

THE KITCHEN GARDEN.

By JOHN DUNN, Kitchen Garden Foreman, Royal Gardens, Windsor.

PARSLEY.—If seeds were sown in boxes in order to produce an early supply, the young plants should now be ready to put out in a sheltered situation. This crop succeeds best on rich soil in a somewhat shady situation. Plant in rows 15 inches apart, allowing 6 inches between the plants in the row. If not already done, a sowing should be made now to afford supplies through the summer and autumn; but for next winter's use a sowing should be made on a west border about the middle of July.

LETTUCE.—Seeds may now be sown on a warm border for raising plants for use at about the end of June. If sown in rows 1 foot apart, the young seedlings may be carefully thinned when large enough to handle, and planted to form a succession to those left in the rows undisturbed. Ideal, Iceberg, and Mammoth White Cos are varieties now being sown at Frogmore for this purpose. If Lettuce seeds were sown in February under glass, the young plants will now be ready for planting on a warm border. Keep a careful watch for slugs, which may be destroyed by applications of hot lime at daybreak.

BEET.—A small sowing of Beet may be made now on a sheltered border. If quick-growing Turnip-rooted varieties are sown, the crop should be ready for use by the end of June. The soil for this early sowing should be light and rich, and the seeds should be sown in drills 15 inches apart and 1 inch deep. When the young plants appear, a careful watch should be kept for slugs, which may be kept in check by frequent, light dustings of lime early in the morning. Beetroot in store should be examined frequently and all young growth removed, placing the roots in a cool position in order to keep them in good condition for as long as possible.

ASPARAGUS.—Seeds may be sown in drills 18 inches apart and 2 inches deep to produce plants for making new beds in two years' time. If the seeds are sown in pairs 6 inches apart, the young plants will require very little thinning,

and may be allowed to grow in the same position for two years.

CAULIFLOWER.—Plants wintered in cold pits should now be gradually hardened off in readiness for planting out during the first week in April. If the weather is favourable, the lights should be removed from the pits as early in the morning as possible, and replaced again at night, maintaining sufficient ventilation to keep the plants from becoming drawn. From the present time onward, Cauliflower plants in pots will require very careful watering, or the plants may bolt before they are large enough to be of any value. If the ground for this crop was trenched and manured early in winter, the surface may now be forked over and allowed to remain until the plants are ready to put out in the first week of April. Before the plants are put out, they should be given a good watering, and the same care will be necessary after planting takes place. When growth commences, liberal supplies of weak liquid manure should be given. If the weather is favourable we set these plants out in the first week of April, and expect to commence cutting in the first week of June.

THE APIARY.

By C. CHOUSS.

FEEDING.—Feeding will be necessary this spring in most apiaries. Last year was generally a poor honey season, and where autumn feeding was not resorted to, or only imperfectly done, the bees may be short of food. In the south of England bees may be fed on syrup after the middle of March, but in northern districts it will be wiser to defer feeding until the end of the present month. Feeding with Beet sugar is said to have favoured the Isle of Wight disease; it will be wise, therefore, to use no other than pure granulated white cane sugar. After a careful examination of the hive, if food is found to be scarce, or likely to be so before the end of May, prepare some syrup, taking great care not to let it burn in making. Use 5 lbs. of sugar, 3½ pints of water, and half an ounce each of vinegar and salt. It is not necessary for the syrup to boil, so that there need be no risk of it burning. If it is brought to a temperature of 120° F., it will suffice, but it must be well stirred, so that all the sugar is dissolved. Where a large quantity of syrup is required, the extractor will be found of great service. Pour in the necessary amount of boiling water, adding the sugar and other ingredients; work the machine, and when the water is raised by the rotary motion, commence to drip in the sugar a little at a time. Treated in this manner, it will soon dissolve. Fill bottles holding 2 lbs. or 5 lbs. with syrup to the brim, and cover the mouths of the bottles with two layers of cheese cloth, or one layer of stout calico, secured by string. If the bottles are not filled, air rising above the syrup, when the bottles are overturned, will cause the syrup to run out. Cover the frames with a strip of wood about ¾ inch to 1 inch thick and 4 inches wide, and cutting out one or two holes just less in diameter than the width of the mouth of the bottles used. It will be a great advantage if two bottles, or even three, of syrup are put on at the same time, to save opening the hives too often, thus economising the heat of the hive. When renewing syrup, a piece of glass or slate may be used to keep in the bees, and this can be slipped aside when the bottles are replaced. Take care not to spill the syrup in the vicinity of the hives, for this is often the cause of bees robbing the food from other hives; because of this, always close the entrances of the hives so that not more than one bee may pass out at the same time.

POLLEN.—Now that there is a supply of pollen available, breeding will increase, but as the supply of pollen will not yet be large, it is well to supplement this food by placing pea flour or oatmeal among some shavings in an old propolis straw skep in a sunny corner. The smell of the propolis is a great attraction to the bees.

QUILTS.—At this time of the year there can scarcely be too much quilting above the brood chamber. Take some well-fitting quilts made of a non-conducting material, and between each layer place a sheet of good brown paper. Conserve as much of the heat in the hives as possible, by seeing that the quilts fit the corners exactly. A section rack fitted with a chaff or cork-dust cushion is the best economiser of heat.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but they cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MARCH 28—
Roy. Hort. Soc. Coms. meet (Lecture at 3 p.m. by Mr. R. C. Reginald Nevill, on "Al-ines in Their Native Homes").

WEDNESDAY, MARCH 29—
Irish Gard. Assoc. and Benev. Soc. meet.

THURSDAY, MARCH 30—Torquay Spring Fl. Sh.

SATURDAY, MARCH 25—
British Gard. Assoc. Meet. at Birmingham. Address by Mr. James Udale on "Examinations in Horticulture."

AVERAGE MEAN TEMPERATURE for the coming week deduced from observations during the last Fifty Years at Greenwich—44° F.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, March 22 (6 P.M.): Max. 59°; Min. 39°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 23 (10 A.M.): Bar. 30; Temp. 49°; Weather—Dull.

PROVINCES.—Wednesday, March 22: Max 51° Cambridge, S.E.; Min. 40° Scotland N.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Herbaceous and Other Plants, Hardy Bulbs, &c., at 12; Roses, &c., at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Hardy Bulbs and Roots, Perennials, &c., at 12; Trade Sale of Miscellaneous Bulbs and Plants, at 12; Roses, at 1.30; Japanese Lilliums, at 3; Palms and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Imported and Established Orchids in Variety, Orchids in Flower and Bud, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

A West Indian Botanist.

The death of Mr. J. H. Hart, which was announced in our last issue, took place at Port of Spain, Trinidad, on February 20. Mr. Hart was born in Suffolk in 1817, and proceeded, in 1875, to the West Indies to take charge of the gardens and grounds of King's House, Jamaica. Six years later he was appointed, under Mr. (now Sir) Daniel Morris, Superintendent of the Cinchona plantations in succession to Mr. W. Nock, who was transferred to Ceylon, and he acted as Director of the Jamaica Botanical Department until the arrival of Mr. W. Fawcett, the new Director, in December, 1886. In 1887 Mr. Hart became Superintendent of the Royal Botanic Gardens at Trinidad. He rendered valuable service in re-organizing the Botanical Department, in instituting an efficient meteorological service, and in starting and editing the *Bulletin* of the Department, which was continued uninterruptedly from 1887 to 1908, when it was merged in the *Bulletin* of the Agricultural Department. He wrote an interesting account of a visit to Nicaragua in 1885, and in 1892 published *A Treatise on the Cultivation and Curing of Cacao*. A second edition of this work was issued in 1900. It is understood that just prior to his death Mr. Hart was engaged in correcting the last proofs of a more compre-

hensive handbook work on Cacao cultivation, which may be issued shortly. He brought out in 1908 a *Herbarium List* of the plants represented in the Herbarium of the Botanical Department at Trinidad. This includes an enumeration of the plants collected by Lockhart, Purdie, Cruger, Finlay, and Prestoe, together with the more recent collection made by Mr. Hart himself, by Mr. F. V. Sherring, Mr. William Broadway, and others. It is hoped that this valuable herbarium will be carefully preserved by the Government until such time as it is possible to bring out a complete Flora of Trinidad and Tobago.

In December, 1909, Mr. Hart edited a volume of *The Ferns and Fern Allies of the British West Indies and Guiana*, by Mr. G. S. Jenman, F.L.S. This had been previously published in parts as *addenda* to the *Bulletin* of the Botanical Department. Unfortunately, owing to some of the parts being out of print, only a few copies of the complete volume are available.

Mr. Hart possessed a wide and intimate knowledge of the economic conditions of the British West Indian Colonies, and took an active part in the proceedings of the Inter-Colonial Agricultural Conferences organized by the Imperial Department of Agriculture. He was specially interested in Cacao and rubber, on which subjects he was a recognised authority. Mr. Hart visited various portions of Central America to make observations on Cacao plantations, and last year, after his retirement, he was engaged to prepare a report on rubber cultivation in Mexico. In Trinidad he will be remembered as having established the St. Clair Experiment Station, and as an active and zealous member of the Agricultural Society. As stated in the *Mirror* of Port of Spain, Mr. Hart "had made many friends, by whom his loss will be severely felt. He spent the best years of his life in Trinidad and did good service there, and the record he leaves behind him is one of which anybody might be proud." The funeral, on February 21, was attended by the Colonial Secretary as representing the Government, by Colonel T. H. Collens, representing the Board of Agriculture, by the Director and members of the staff of the Department of Agriculture, by a detachment of the Light Infantry Volunteers, of which Mr. Hart was a retired captain, and other public bodies.

The German Dendrologische Gesellschaft has done much to promote the introduction and cultivation of hardy trees and shrubs into Germany, and the results have been most satisfactory. Trials made in numerous localities have afforded valuable information on the cultivation of numbers of species and varieties which were previously regarded as unsuitable for the climate of Germany. On various occasions we have printed extracts from the Society's publications; some of these have related to purely

ornamental subjects and others to timber trees and shrubs of economic value. The general result of the Society's work has been a large addition to the number of species which were cultivated, say, a quarter of a century ago. Dr. Edmond Goeze, an old Kew man of the early 'sixties and subsequently successively curator of the Botanic Gardens of Coimbra, Portugal, and Greifswald, North Germany, has devoted much time to the description of the most famous collections in North Germany. His later contributions to the subject have mostly appeared in the *Oesterreichische Garten-Zeitung*, and the descriptive part has already been noticed in these columns. We have now been favoured with a reprint of Dr. Goeze's list of hardy trees and shrubs cultivated in European Gardens from the earliest times. It is not claimed for this work that it is complete, but it comprises some 2,000 species and numerous varieties, and should prove very useful for present reference and as a foundation for a future history comprising greater detail. The arrangement is systematic, under the countries of origin; the system followed being that of Bentham and Hooker's *Genera Plantarum*. Beginning with Europe and ending with America, the author gives the authorities for the names; the date of introduction into cultivation, name of introducer, or establishment where cultivated, so far as ascertained, or simply the earliest record of being in cultivation. Considering the immense amount of time that must have been given to the compilation, it seems a pity that the sources of information are not included, especially as there is a waste of space that would have been ample for the usual abbreviated references. Such an addition would have been of the greatest assistance to those who wish to pursue their inquiries further. The earliest records date from the middle of the sixteenth century, but it should be mentioned that, whilst the Gooseberry and Red Currant are included, there is no mention of such plants as the Grape Vine and Fig. A few historical particulars are given at the end of each list, which might be profitably extended. The Chinese and Japanese plants are treated in greater detail than those of any other country, the list being preceded, in this instance, by a more detailed historical sketch of the progress of botanical discovery in China and Japan.

SUPPLEMENTARY ILLUSTRATION.—Belvoir Castle, the beautiful country seat of the DUKE OF RUTLAND has long been renowned for its spring flower-bedding, the gardens at this season appearing as though painted in gorgeous masses of colours. The two views given in our picture show how extensively this system of planting is practised there, and how skilfully the subjects are arranged by the gardener, Mr. DIVERS. Spring gardening has scarcely any limits; it may not only be employed in the formal garden, but also to beautify the grounds, including the wilder parts, as well as to embellish stream and lake. The variety of subjects that can be employed afford great possibilities to produce varied and charming effects.

Photographs by H. N. Rose

SPRING FLOWER-GARDENING AT BELVOIR CASTLE.

and at a season when out-door flowers are doubly welcome. They burst on the scene when everything in the garden appears to be awaking afresh into life, and continue in bloom until the tender subjects are ready to take their place. Perhaps the more informal planting of the subjects, such as is seen in the winding breadth of flowers in the upper picture, afford the best and most natural effects. But where set beds have to be arranged more or less formally, in order to harmonise with their surroundings, batches of bulbs or other subjects in distinct colours, carpeted

nolias, Rhododendrons, species of Pyrus and Prunus, Almonds, Hammels of sorts, Forsythia, Ribes, and other species.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees of this Society will take place on Tuesday, the 28th inst. In the afternoon a lecture on "Alpines in their Native Haunts" will be delivered by Mr. R. C. REGINALD NEVILL.

THE KING OF PORTUGAL AND THE R.H.S. SHOW.—The KING OF PORTUGAL was amongst the

inducement to the nursery trade to accept the invitation extended to them to decorate the numerous beds. In addition to the permanent exhibits, there will be two exhibitions of cut Roses in structures specially arranged for the purpose. Particulars can be obtained from Mr. F. G. W. HEMSLOW, M.A., Empire House, 175, Piccadilly, W.

ROYAL WARRANTS TO NURSERY AND SEED FIRMS. Messrs. CLIBRANS, Altrincham, have been appointed, by Royal Warrant, Nurserymen to the KING.

ROYAL INSTITUTION.—The annual meeting of the members will take place on Monday, May 1, and the general monthly meeting on Monday, May 8. On May 5, Professor MARTIN O. FORSTER, D.Sc., will deliver a lecture on "New Organic Compounds of Nitrogen," and on May 12 Professor WILLIAM STIRLING, M.D., will give a discourse on "Biology and the Cinematograph."

ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.—For the purpose of assisting the promotion of this exhibition, the Executive Committee invited prominent horticulturists in the various counties to act as provincial secretaries. The first duty of these secretaries was to get together a committee and chairman for each county, and the committees were to do what was possible to encourage local cultivators to participate in the exhibition. They were also to obtain subscriptions and guarantees, and in various ways to popularise the exhibition in the counties. At the invitation of the Executive Committee, a number of the secretaries, including representatives from Wales and Ireland, attended a meeting on the 14th inst., at the Hotel Windsor, Westminster, for the purpose of conferring as to the best means of carrying out their work, and for the purpose of receiving from the chairman of the Executive Committee, Mr. J. GURNEY FOWLER, information upon the progress which has been made since the last meeting. Mr. FOWLER first delivered an address, in which he showed that everything was being done to push forward the work of organisation as rapidly as possible, and he described the ways in which the provincial committees could best support the efforts of the Executive Committee. Following the chairman's address, there were speeches from many of the provincial representatives, some of whom sought information. On the whole, the reports were of a reassuring character, for whilst some had encountered considerable difficulties in their initial proceedings, others had succeeded in gaining the support of all whom they had approached. On behalf of the Executive Committee, Mr. FOWLER promised that certain suggestions advanced by the delegates should be adopted. In the evening of the same day, the party joined the members of the Horticultural Club at dinner.

SHOOTING OF WOOD PIGEONS.—In view of the complaints which have been received by the Board of Agriculture and Fisheries as to the depredations recently committed by wood pigeons, the Board desire to suggest to landowners, farmers, and gamekeepers that they should make a combined effort during the coming week to reduce the numbers of the pigeons in their neighbourhood. It is probable that many of these birds are migrants, and have not yet settled in any district, so that if the steps suggested by the Board are taken many of the pigeons now attacking crops may be prevented from becoming settlers, even if a large number of birds are not shot. A special attempt should be made to shoot pigeons late in the evening, so as to drive them from the woods or other cover in which they roost.

visitors of the R.H.S. Show on Wednesday last. He took great interest in the Hybrid Gerberas exhibited by Mr. H. N. ELLISON, and selected a few of the bloom to take away with him.

FESTIVAL OF EMPIRE EXHIBITION.—Nurserymen and seedsmen are invited to make exhibits in the grounds of the Crystal Palace with a view to decorating the gardens during the Festival of Empire Exhibition, which will be opened in May next and continue until October. It is thought that the presentation of imperial awards in the form of cups and medals will form a sufficient

[Photograph by H. N. King.]

FIG. 82.—BELVOIR CASTLE ENTRANCE TO THE KITCHEN GARDEN.
(See also Supplementary Illustration)

with such plants as Arabis, Myosotis, Saxifrages, Violas, or Daisies, form pleasing pictures. Gaudy Tulips and erect-growing Hyacinths, when relieved with Wallflowers, Polyanthus, double-flowered Arabis—which grows quite tall in company with the bulbs—or Forget-me-Nots in blue and other shades, produce imposing colour scenes of great beauty. In the outlying parts of the grounds, spring flowers associate well in the grass, even beneath trees, whilst nothing is more beautiful than a bank or mound studded with a variety of these lovely subjects. They find a fitting company in spring-flowering shrubs, including Mag-

BOSKOOP POMOLOGICAL SOCIETY'S JUBILEE SHOW.—The exhibition to be held at Boskoop from April 5-16 has the patronage of Prince HENRY of the Netherlands. The Secretary of Agriculture, Industry and Commerce for Holland, and the Commissioner of the Queen for South Holland have been appointed vice-presidents; the Under-Secretary of Agriculture and the Mayor of Boskoop will act as honorary president and president of the committee of honour respectively. The exhibits will be judged by an international jury composed of 60 horticulturists, with Mr. J. C. DE MARES OYENS, Chairman.

GARDEN PICTURES AT THE MODERN GALLERY.—At the Modern Gallery, New Bond Street, an interesting exhibition is being made by two lady artists, Lady CONSTANCE EMMOTT and Mrs. RUSSELL WALKER. Lady EMMOTT contributes 56 pictures in oil and watercolour of West Highland and other subjects, which show both conscientious work and a close appreciation of Nature. Three of her larger pictures are: "After Storm, in the Sound of Mull" (58), "The Dhu Loch Avenue, Inveraray" (39), and "An Hour of Peace" (40). Of the smaller ones "An Easterly Haze" (50) and "Aros Castle, Mull," (17), impart a feeling of calm restfulness. Mrs. WALKER'S pictures, in water-colour, are mostly of gardens. The colour schemes are good and the subjects pleasantly suggestive. Although most of the gardens are in England and Scotland, one or two recall the beauties of Italy; in "The Castle Garden, Inveraray" (51), one's mind is transported to the Villa Carlotta on Lake Como, while "Farnborough Hall Garden, Warwickshire" (56), is quite classic, with the tall Cypress trees like sentinels behind the terrace steps. "Rhododendrons" (7) is very strong in colour and one of the best. "Dalcenna, Argyll, N.B." (2), "The Sun's Good-night" (14), "A Peep of the Solent" (50), "Under Chichester Spire" (23), and "All in a Garden Fair" (57) are very pleasing and artistic in feeling. Of the smaller pictures may be mentioned "The Old Blue Pump" (63), "A Corner of the Garden" (67), and "Evening in Chichester Fields" (33).

A BACTERIAL DISEASE OF POTATOS IN IRELAND.—Several different bacterial diseases of the Potato plant have been identified in recent years. The best known of these maladies are caused by *Bacillus solanacearum* and *Bacillus phytophthorus* respectively. The former disease producing bacillus was discovered by G. F. SMITH in the United States, and the latter has been fully described by APPEL, in Germany, where the symptoms to which it gives rise are known as "Black-leg." The first species of bacterium causes the leaves to wilt and shrivel, produces brown streaks on the haulms and, subsequently, affects the tubers, while the other induces a black rot in the stems and tubers of affected plants. A bacterial disease of Potatos, described by PETHERIDGE and MURPHY in the February number of the *Proceedings of the Royal Irish Academy*, occurs somewhat extensively in Ireland, and appears to be caused by a species which is not identical with either of the pathogenic forms previously discovered. The characters of this disease in Ireland are similar to those of the "Black-leg" disease in Germany, and, in fact, the authors suggest that it should be called "Black Stalk rot." The foliage of affected plants becomes discoloured and dries up, the veins of the stem become brown, the underground part of the haulm decays, and, subsequently, the tubers rot. The organism, when studied in pure cultures, is found to differ in some respects from *Bacillus phytophthorus*, and the name *Bacillus melanogenes* is suggested for it. "Black Stalk-rot" in Ireland makes its appearance early in the season, coming considerably before Late blight

(caused by *Phytophthora infestans*) is conspicuous. Experiments clearly show that the planting of affected "seed" is mainly responsible for the spread of this disease, which not only causes loss in the growing crop, but also during storage. It is possible that the disease may also be contracted from the soil. The authors suggest that preventive measures should aim at the destruction of diseased plants, the exclusion of affected tubers from the pits, and the procuring of Potatos from fields where the disease is absent.

VARIETIES OF SCAB IN POTATOS.—Potato growers should provide themselves with the Leaflets (Nos. 94, 105, 137, and 232), published by the Board of Agriculture and Fisheries, which describe the various forms of scab by which Potato tubers are affected. Leaflet 137, which is the most recent of the series, enumerates five kinds of scab, due each to a different agent. In addition to Black Scab (Wart disease), to which we have had occasion to refer frequently of late, the other "scabs" are:—Corky scab, due to the infection of tubers by *Spongospora scabies*; Oospora scab caused by the fungus, *Oospora scabies*; scab due to mechanical injury, and that caused by Millepedes. The scab due to *Oospora scabies* is very widespread, and takes the form of rough patches, which may be scattered or may cover the surface of the tuber almost completely. Though affected tubers are not otherwise damaged, they are rendered so unsightly that their market value is greatly reduced. This form of scab may be distinguished from the others by the presence of a delicate greyish bloom on the diseased portions of the tubers. "Seed" sterilisation and planting on ground which has not borne a scabby crop are the precautions which should be adopted to prevent this disease. For the sterilisation of the tubers, immersion for two hours in formaline (one pint of commercial formaline to 36 gallons of water) has been proved to be efficacious. After immersion the tubers are spread out to dry, and may then be cut and planted in the usual manner. It is to be noted that, according to Leaflet No. 137, various other crops, viz., Beet, Swedes, Carrots, and Cabbages, are susceptible to attack by *Oospora scabies*, and therefore such crops should not follow one of diseased (scabby) Potatos. In affected gardens and allotments where Potatos are grown year after year, it is suggested—following Massee—that the trenches in which Potatos are to be planted should be sprinkled with powdered sulphur. Lime appears to favour the development of this form of scab; whereas nitrate of potash (2 cwt. per acre) is said to produce beneficial results. The scab caused by millepedes, chiefly by the "false wire worm," *Julus pulchellus*—the Potato's worst enemy—is the result of these insects feeding on the flesh of the tubers. In response to the irritation thus set up, the Potato produces masses of cork which take the form of raised, scabby borders round the shallow cavities made by the millepedes. No effort should be spared to rid the soil of this pest, which is introduced not infrequently in leaf-mould or other decaying vegetable matter. (See Leaflet No. 94.)

PALMS IN CALIFORNIA.—American gardeners of the Southern States and on the Pacific coast are fortunate in the enjoyment of a climate in which large numbers of species of Palms flourish in the open. In the course of an interesting article on the Palms of California (*The American Florist*, February 25, 1911), Mr. W. H. TAPLIN enumerates various of the species which grow well in the open in those regions. *Washingtonia filifera*, the Californian Fan Palm, is grown largely, and is often planted in avenues in the way that the Royal Palm, *Orodoxa regia*, is used in Brazil and

Cuba. Of the species of Phoenix, *P. canariensis* is grown most commonly, and proves to be comparatively hardy, a rapid grower, and, needless to say, very ornamental. *P. dactylifera*, the Date Palm, has been naturalised in Arizona, and the Government is seeking to establish colonies of this Palm with a view to its economic use. Other Phoenixes grown out-of-doors include *P. reclinata* and *P. rupicola*. With reference to the members of this genus, Mr. TAPLIN makes the interesting remarks that they are very variable, that many seedlings differ considerably in form from their parents, and that there are many garden hybrids. The Coconut Palm, *Cocos nucifera* occurs frequently in the warmer parts of the Southern States, and is found in a semi-wild condition on some of the Florida keys. *C. plumosa* flourishes in Los Angeles as does also *Livistona (Corypha) australis*. *L. chinensis*, which is quite hardy in Cornwall, does not grow so well in California as the hardier *L. australis*. No doubt in the most sheltered regions of the North American continent many other species could be grown; but, as Mr. TAPLIN remarks, the Californian landscape gardener has already for ordinary purposes an adequate number of these most graceful of trees.

A NEW HYBRID DEUTZIA.—*Deutzia discolor elegantissima*, raised by Mr. LEMOINE (Nancy), and described and illustrated in the *Revue de l'Horticulture Belge*, is an attractive hybrid raised from *D. scabia* × *D. discolor purpurea*. The long, flower-bearing branches are erect and slender, bearing inflorescences in axillary corymbs. Each cluster consists of 15 to 18 flowers. The flowers are white with a rosy flush, have yellow anthers, and are upwards of ½ inch in size. Flowering lasts a long time, and the later flowers are of a bright rose-carmine colour.

GERBERA HYBRIDA.—Mr. H. N. ELLISON exhibited remarkably fine flowers of *Gerbera* at the R.H.S. meeting on the 14th inst. Seed of *Gerbera* requires careful handling to get a good growth. After filling the pot or pan with a compost of loam, leaf-mould and sand, the surface must be made smooth and firm. The seeds may then be scattered over it, and, with a fine-pointed stick or large needle, the actual seeds should be pressed into the soil, leaving the pappus still on the surface. If the pappus is covered with soil, germination seldom takes place. When the seedlings are large enough, pot them off singly keeping them in partial shade at first, and watering them but sparingly.

F. McLeod, with eight coloured plates; Present-Day Gardening Series. (T. C. and E. C. Jack.) Price 1s 6d.

THE ROSARY.

CULTURAL NOTES FOR APRIL.

There is one point in pruning Roses which needs more attention than it receives. Unless we cut back close to the eye, dead wood is certain to result above it, and as this does not callus over the stem boring sawfly has a better chance of access. This pest becomes more prevalent year by year; perhaps because Roses are more generally cultivated, but also because this dead wood is so often left to encourage and harbour the larvae.

Standards of weeping varieties, such as the Wichuraianas and some of the Ayrshires, will be well if trained out wider than is ordinarily done, thus allowing more room for the wood and securing a better effect. Many con-

established Roses, and make firm by treading any newly planted, doing this when the ground is in a suitable condition.

Towards the end of the month there will be several suckers pushing from the stems of standards, and they should be removed at once. Standards budded last season may have a few young growths left upon the short length of shoulder beyond the buds. The idea of leaving these is to encourage more sap to rise to the support of the young Rose. They should be removed gradually as the Rose bud pushes into growth. It is different with budded dwarfs, where the sap must necessarily come to the bud, having no other outlet.

In warm positions and open walls, early growth may be affected by morning frosts. In that case syringe with cold water, so that the thawing may not be so rapid when the sun reaches them.

ventilation owing to sudden changes from bright sunshine to dull, cool weather. Much may be accomplished by a frequent use of the two specifics Mo. Effic and Cyllin soft soap advised in my last notes. Roses like sunlight, but it is apt to distress young growth through clear glass, and it may be necessary to provide some shading. By all means let this be very slight. Perhaps the best and least unsightly is Summer Cloud, put on very thinly thus early in the season. This can be applied easier when hot. Other washes may be used so long as only the burning power of the sun is checked.

Much good is done by occasionally turning the plants half way round, at the same time moving the surface soil slightly. This handling of the plants gives a better idea of their water requirements, and allows light to reach them from a different point.

FIG. 83.—MESSRS. JAMES CARTER AND CO.'S EXHIBIT AT THE R.H.S. MEETING ON THE 14TH INST.

(See p. 171 ante)

trivances can be rigged up for this, and will answer the purpose, so long as they are sufficiently strong to bear the strain when the plants are heavy with growth and blossom. All standards should be made quite secure now. Swaying is one of the most harmful things that can happen to them. Here again, varied supports can be used, but they must be strong, and perhaps the most permanent are lengths of gas or water piping, which are lasting, strong, and not nearly so cumbersome as wooden stakes.

A capital and immediate effect may be produced by planting out climbers from pots. These will not need cutting down to the base, as will plants from the open, while the wood is more valuable because of its better maturity and freedom from effects of frost. Blank places upon arches and pergolas may be filled up in this way. Finish moving the surface soil among

No time should be lost in planting dwarf stocks for budding during July and August. Plant with the roots as near the surface as possible.

ROSES UNDER GLASS.

Pot plants in full growth will need feeding. Almost any liquid manure is suitable, and Roses appreciate a change of food. Another method of feeding is to slightly stir over the surface soil and sprinkle some artificial manure on it. Standen's, Clay's, and bonemeal are very useful, and more steady in their action than guano and superphosphates. When sprinkling these manures around pot plants water well, and slightly cover with a little fresh compost. A very thin layer will de-colour the mixture and prevent any unpleasant appearance.

March is the most troublesome month as regards mildew, because of the difficulty in

Keep the young growths of climbers away from the glass as much as possible, or the tender points with flower buds will often be destroyed. I must again point out the great advantage of slight fumigations followed by syringing in the morning.

A few stocks in pots might be growing among the Roses now. These will soon be very useful to bud a few choice varieties on, the buds coming from the first growth below the flowers. This will avoid any waste from slight pruning when cutting flowers or trimming back after they have faded on the plant. A little of this "summer" pruning might well be practised upon pot plants, and it would serve to keep them in better shape.

Now, and during next month, we can get cuttings of semi-ripened growth. The cuttings may be obtained from below a flower, or

any of the blind or flowerless growths may be cut off with a slight heel. Only remove the lower leaf or leaves, and insert the cuttings in a compost of half sand and loam. If kept quite close they will root in the same temperature, but a little bottom heat is better. It is not absolutely necessary to have a heel, but cut off the shoot close below an eye, not removing any of these as recommended when making stocks for working other varieties upon.

Practice.

PLANT NOTES.

CLADOTHAMNUS CAMPANULATUS (GREENE).

A SHORT note on *Cladothamnus pyrolæflorus*, as figured in the *Botanical Magazine*, appeared in *Gardeners' Chronicle*, December 31, 1910, p. 487.

I have discovered another species, *Cladothamnus campanulatus* on the mountains near Vancouver. Not much appears to be known of the cultural requirements of these plants, therefore the following details may prove useful:—

C. campanulatus grows wild on the high mountains of British Columbia and the adjacent State of Washington, U.S.A., and is not found much below 4,000 feet.

At that elevation the snow does not disappear until July, and as it reappears again at the end of September, the season of growth is very limited. The plant forms a shrub 4 to 6 feet high, growing in company with *Rhododendron albiflorum* in a rich humus under the shade of Fir trees, where these are not too dense. The curiously-tinted flowers are produced one on the end of each young growth, providing a succession of blooms. The style is long, declined, and incurved at the end, like a capital J.

The chief value of the plant for garden purposes lies in the unusual colour of the flowers—which are a deep terra-cotta shade, and the pleasing freshness of the foliage. The seed vessels are attractive in winter. The plant apparently enjoys a considerable amount of moisture at the roots. *B. Glendenning.*

PLUMBAGO ROSEA.

PLUMBAGO CAPENSIS is a well-known plant in gardens, but the beautiful *P. rosea* is not often met with, notwithstanding that it is easily cultivated and lends itself to either table or room decoration. Sprays of flowers arranged in small glasses with white Roman Hyacinths or Narcissus and Fern form a charming combination and remain fresh for a considerable time. The flowers are also very useful for mingling in tall vases with *Eulalia japonica*. As a pot plant for room decoration it is especially valuable as the foliage is of a dark green colour, and the flowers are retained on the plant for a long time. After the flowers are cut, the plants should be allowed a period of rest by reducing the amount of water afforded and giving them a slightly lower temperature. If the soil has become sour, the plant should be turned out of its pot, the ball of earth reduced, repotted and placed in a warm house. As the first shoots to be developed are invariably flower-spikes, these should be kept pinched off till others appear at the base of the plant. The lower shoots are suitable for cuttings which strike freely in spring and summer. As soon as they are rooted, the cuttings should be potted and placed in a warm temperature to forward the growth. Keep the plants potted as required; the later struck plants, if kept in small pots, make good specimens for decorative purposes. As September approaches the plants should be allowed a cooler temperature—55° to 60° at night-time being sufficient. This lower temperature will help to mature the wood and hasten the development of the flower-spikes. *Plumbagos*, when established in pots, should be given weak liquid manure and soot water. *A. B. Waddell, Englefeld Gardens, Reading.*

AN INDIAN GARDEN.

THE annual report by the Superintendent of the Gardens of His Highness the Maharana of Udaipur, Mewar, contains much interesting information. It shows, moreover, what strange and new problems beset the British gardener when he goes abroad to take charge of gardens in such a country as India, and how successfully he attacks them. He goes to a land where fruits like the Grape and Peach and Plum ripen during the rainy season; where the most pestilent weeds are *Euphorbias* and *Opuntias* which we cultivate in our conservatories; where the camel is the greatest enemy to the tree planter, and the white ant may throw up such masses of clay in a single night as to so completely bury the Roses of the Rose garden that only a twig here and there is to be seen. Nor are these the most serious difficulties with which the horticultural pioneer has to contend. The native does not greatly believe in such operations as pruning, and appears to think that the reply "Forgotten, sir," is a final and convincing answer to the question why he has not done such and such a thing. Then over the Indian garden there may fall, as there fell at Udaipur last year, the black shadow of the plague, and, despite the resolute efforts of His Highness the Maharana and of the Residency Surgeon, take its toll of victims. Garden water-carts are turned from their routine uses to distribute disinfectants through the city. "It was really a sad time; every road one went one could see the bodies being carried away," thus the report paraphrasing unconsciously the scene depicted by Shelley in the garden of the Sensitive Plant.

"The weary sound and the heavy breath,

And the silent motions of passing death."

And the report continues, "It was quite three months before the garden hands returned to work with many blanks among their number." The Superintendent, Mr. T. H. Storey, formerly of Edinburgh, had remained, having in the meantime shifted his garden office, in which dead rats—the plague bearers—had been found, to a place in the open under the shade of a large Mango tree. After the grim interlude, the garden hands returned to aid in the carrying out of trials in Poppy-growing for opium, and to their routine of work and of forgetting.

Luxuriant growth and sudden cataclysms seem to be the rule at Udaipur. Sweet Peas, *Achimenes*, *Eucharis*, *Agapanthus*, *Caladiums*, and *Liliums* all do well till a sudden storm of hail makes such havoc that "the garden flower-pot makers are kept hard at work for a long time renewing the thousands of pots that were smashed by the hail."

The crops of Carrots, Parsnips, Beet, Lettuce, Radish, and Turnips were good; Cauliflowers were a success and popular. Leeks, though they grew successfully, were not to the native taste; vegetables which come late are reduced to ashes by the scorching winds of March, and what the winds spare is attacked by mildew and devoured by maggots.

Beyond the gardens is the jungle, and when the excitements of gardening pall there are wild boars—which root up almost everything, but which will have nothing to do with the *Euphorbias*, and tigers, to give sport to the adventurous.

Despite the wild boars and tigers and the spiny *Euphorbias*, the jungles of Khas Odi, which surround Udaipur, are dear to the superintendent's heart, and "their autumn tints are simply lovely." That the superintendent is a Scot is evident from internal evidence contained in the report; thus, "Khas Odi is considered to be one of the most beautiful places about Udaipur with its Scottish hills and lakes, and the only thing wanted is the Heather and Whins to finish them off and to give them a home-like appearance." We may well believe that, though Mr. Storey, like the true Scot he is, welcomes the life not devoid of adventure in this

Indian garden, reflects, at times, that "East or West, Home's best." Nevertheless, through times of plague and through the torturing change of climate he, like thousands of fellow Britons in that land, stands to his post. It is well that he and they should know that by those of us who understand their life and work, though the fates compel us to stay at home, their steadfastness is held in honour.

NOTES FROM SCOTLAND.

ABERDEEN SWEET PEA SHOW.

IT is proposed to hold a Sweet Pea show in Aberdeen during August. Mr. James Esslemont has been appointed chairman of the committee, and the secretarial duties will be undertaken by Mr. M. H. Sinclair. There are many cultivators of Sweet Peas in the Aberdeen district, which is an excellent centre for such a show. There will be sections for professional and amateur growers, as well as decorative classes open only to lady exhibitors.

FORESTRY INSTRUCTION.

AT a recent meeting of the Governors of the Edinburgh and East of Scotland College of Agriculture it was reported that the Forestry Committee had, with the collaboration of Dr. A. W. Borthwick, prepared a syllabus for a course of instruction in forestry. The course, which is intended for practical foresters, will last for a month, and will probably be held in June.

CHILDREN'S BULB SHOWS.

COMPETITIVE exhibitions of bulbs, at which prizes are offered, for school children, are held in several of the leading cities and towns in Scotland. Dundee has for a considerable time carried on such exhibitions, Lady Carlaw Martin taking a special interest in them. At Dunfermline the show has the support of the Carnegie Dunfermline Trust. In some cases the bulbs are given free, and in others they are sold at a very cheap rate to the children. The compost is generally supplied from the public parks free of charge.

HARDY PLANTS AT GLASGOW BOTANIC GARDENS.

WITHIN the last three or four years, the collection of border and Alpine plants at the Glasgow Botanic Gardens has been much enlarged. Difficulty has been experienced in the cultivation of many genera and species, owing to the damp climate and the deleterious fumes from chemical and other works. Many of the plants have to be housed in frames all the year round.

A WORKHOUSE GARDEN IN LEWIS.

THE Governor of the Lewis Combination Poorhouse at Stornoway, in the island of Lewis, is Mr. Drummond, who was originally a gardener by occupation. He still takes great interest in horticulture, and sees to the cultivation of the garden attached to the poorhouse. All the vegetable supplies of the house are cultivated on the spot, and a considerable revenue is derived from the sale of horticultural produce to the vessels which call at the harbour or are stornbound there.

PRESENTATION TO MR. JOHN DAVIDSON.

A NUMBER of past and present students of the Botanical Department of Aberdeen University assembled in the botanical classroom recently to present to Mr. John Davidson, assistant in the department for the past 13 years, a handsome writing case and purse of sovereigns, in token of their appreciation of his services, and as a mark of their esteem, on the occasion of his intended departure for Vancouver. Mr. C. O. Farquharson, M.A., presided, and the presentation was made in suitable terms by Mr. Peter Leslie. Dr. James W. H. Trail, Professor of Botany in

the University, said that long after Mr. Davidson had gone the department would continue to show the work he had done. Especially could that be said regarding their botanical museum, which contained many specimens that retained practically their natural colour by the effective treatment to which they had been subjected by Mr. Davidson's special method—specimens treated in such a way as not to have their equal in any museum in the world.

LORD PENTLAND ON GARDENS AND PARKS.

IN the course of an address delivered in Edinburgh on March 16, in connection with the Town Planning Exhibition, Lord Pentland, Secretary for Scotland, contrasted the relative positions of Edinburgh and Glasgow with regard to open spaces, and said that the total area of public parks, gardens, &c., in Edinburgh, extended to 1,447 acres, including the Royal Botanic Gardens, and the King's Park at Holyrood, for a population of 317,459; while Glasgow has only 1,279 acres, with a population of 775,594.

THE BULB GARDEN.

NOTES ON LILIES.

MENTION of the beautiful *Lilium Szovitzianum* by Rev. D. Williamson (see p. 145) induces me to say a word or two concerning its cultivation. In common with several other members of the Martagon family, it is often seen to very little advantage the first season after planting, and I have known it to be condemned hastily for this reason. In order to grow *L. Szovitzianum* it does not require any elaborate preparation, the main essentials being a good deep loam, which is at the same time effectually drained. Into this loam the elongated, tong-like roots from the base of the bulb will penetrate deeply, and it is only when the bulb is thoroughly established in this way that this Lily is seen at its best. The first season after planting the display is generally a meagre one, but, providing the conditions are favourable, a marked improvement takes place each year. Other members of the Martagon group behave in a similar manner, notably, *L. Martagon* itself and its varieties, and *L. chalcedonicum*, known generally as the Scarlet Martagon. These Lilies are seen at their best in a good deep, loamy soil. Strange to say, a prominent Japanese representative of the Martagon family, namely *L. Hansonii*, can always be depended upon to flower well the first season, provided it escapes the late spring frosts, which sometimes injure the young shoots.

Concerning the late blooming of *L. speciosum* referred to by Mr. Williamson, the blossoms are even in the southern half of England often affected by the damp cold nights. After the Japanese bulbs have been grown for one season in this country they flower decidedly earlier than freshly-imported bulbs, whilst those grown in Holland (from whence at one time we used to obtain all our supplies) are earlier still in blooming.

With regard to *L. Kramerii* and *L. rubellum*, the experience of your correspondent coincides with my own. For some years we have been told that to succeed with these tantalising Lilies they should be raised from seeds, but though one or two promising instances have been recorded, I have yet to see a thoroughly established and flourishing group of either of them. A Lily whose affinities and origin have always puzzled me is *L. Brownii*, referred to in the article in question as coming from Chinese and Japanese regions, but though a large number has passed through my hands I have never found amongst them the true *L. Brownii*, that is the species grown for a very long period by the Dutch, and sent annually to this country. One often hears of *L. Brownii* from Japan, but that is quite a distinct Lily, probably either *L.*

odorum or *L. japonicum colchesteri*, for both have been applied to it.

With regard to Lilies that need to be thoroughly established before they are seen at their best, it may be pointed out that this is to a great extent influenced by the amount of roots pushed out from the base of the stem. In some of the members of the Martagon section, such as *L. chalcedonicum*, *L. Martagon*, and *L. Szovitzianum*, stem roots are produced very sparingly, whereas in most of those composing the Eulirion, Archelirion, and Isolirion groups these roots are very numerous, and a good display of flowers can be reasonably anticipated the first year. Among the better-known Lilies, examples of those that produce these stem roots in such quantities that for the first season the flowers are developed almost independently of those from the base of the bulb, are to be found in *L. auratum*, *L. speciosum*, *L. longiflorum*, and *L. croceum*. It naturally follows that those species in which this character is most pronounced are better suited for pot culture than those which need to become thoroughly established before they are seen at their best. The market cultivators who grow some of the most popular Lilies by thousands, all recognise the important part that these stem roots play towards the development of the blossoms. W.

TREES AND SHRUBS.

THE FORSYTHIAS.

JUST as winter is merging into spring the Forsythias stand out among the most attractive of our hardy shrubs, their bright yellow blossoms being then borne in the greatest profusion.

From its beauty and adaptability to different methods of treatment, the first place must, I think, be assigned to the Chinese species *Forsythia suspensa*. This may be described as a deciduous shrub of a rambling nature, which, with support, will rise to a considerable height. As a wall plant it is delightful, for if the main branches are secured to the wall and immediately after flowering the long flexible shoots are pruned back to within two or three eyes of the base, it will break freely into growth. The shoots then pushed out should be allowed to dispose themselves at will, and the result will be most pleasing and informal, while in the following year these new growths will be wreathed with flowers. As soon as the flowers are past the plant should be treated as before. Not only is it charming on a wall, but as a quick-growing subject for clothing a trellis or for any similar purpose it is excellent. Planted in a shrubbery border and partially supported by its associates, it is, especially if these are of an evergreen nature, seen to great advantage. Of late years *Forsythia suspensa* has been frequently treated as an open shrub, and in this way it has proved to be highly satisfactory. The method employed is to take young vigorous plants and put them in some good soil. In early spring they are cut back to within 2 or 3 feet of the ground, the result being the production of numerous strong upright shoots, that will the next year give a wealth of blossoms. The after treatment consists of an annual pruning and a liberal top-dressing of manure. *Forsythia suspensa* grown in this fashion forms a yearly feature at Kew, its beauty being enhanced by carpeting the ground beneath with some of the low-growing, blue-flowered bulbs that bloom at the same time. When forced into bloom this *Forsythia* is also valuable for the embellishment of the greenhouse or conservatory. As *F. suspensa* varies a good deal in habit, shape of the leaves, and other particulars, according to the conditions under which it is grown, different names have been applied to slight forms or modifications of it. As *F. Fortunei* and *F. Sieboldii* it is often to be met with in gardens and nurseries. *F. viridissima* forms a far more compact bush than the *F. suspensa*, and the bark of the young branches is green, and not brown, as in

F. suspensa. As a rule *F. viridissima* does not flower so freely as *F. suspensa*, while the blossoms are also a little later in expanding. Another distinguishing feature is the fact that in *F. viridissima* the lanceolate leaves are always entire, whereas in *F. suspensa* they are often lobed. Of *F. viridissima*, there is a variety with variegated leaves, but its ornamental qualities are not of a high order. *F. europaea*, the newest of the Forsythias, attracted a great deal of attention when first introduced from Albania a few years ago. The presence of a member of the genus in that part of the world was in a general way quite unsuspected, and doubts were at first cast upon the matter. It, however, proved to be quite distinct from either of the species above mentioned, but as a garden plant greatly inferior to them. It is a weak growing bush, whose leaves are unusually thick in texture, while the flowers are but sparingly produced. *F. intermedia* is the name given to a valuable hybrid between *F. suspensa* and *F. viridissima*. It was raised and distributed about 20 years ago by Herr Zabel, of Münden, Hanover, who was also the raiser of the delightful *Spiraea arguta*, one of the most beautiful of all the shrubby members of the genus. In habit and other particulars *F. intermedia* is about midway between its parents. Being more shrub-like than *F. suspensa* it is preferred for certain positions. W.

THE ALPINE GARDEN.

AQUILEGIA FLABELLATA.

THIS delightful *Aquilegia*, although it grows only a few inches high, bears flowers which are remarkably large for the size of the plant. Generally they are white, not too cold and clear, but tinged with a soft, creamy shade, which is charming, or they may be shaded a very light blue with a whitish centre. It is difficult to decide which is the prettier of the two shades. The leaves are light green. With regard to the cultivation of the plant, it will flourish in exposed positions, and also in partial or entire shade. It prefers a half-shady position better than any other, and has also a preference for the rockery over the border, but does not mind much where it is placed, being perfectly hardy. The best way to raise a stock of plants is by sowing seeds, in spring, under glass, or in May or June in the open, in shallow drills in a bed of fine soil. Germination will be a little irregular, and some of the seedlings may not appear until the second season. S. Arnott.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

HUTCHINSIA ALPINA.—May I be permitted to fully endorse all that Mr. S. Arnott says about this plant, until he speaks of it as "this North American flower." Even if it has been recorded from "North America," it is a pity to describe such a well-known Alpine plant as "North American" when it grows from one end of the European Alps to the other, and is also common in the Pyrenees, Spain, Jura, Apennines, and Carpathians. There is a great tendency in catalogues and elsewhere to state that some common European plant hails from a remote region of the earth, other than that of which it is characteristic; and it is to be regretted simply on the score of the dissemination of misleading knowledge. One otherwise excellent catalogue of hardy plants was greatly marred in this way. It is quite unnecessary to describe a common European Alpine plant as Japanese or Siberian, or a rock-plant as Algerian which may be far more characteristic of the flora of Southern or Central Europe. Occasionally even British plants have been treated in this way. H. S. Thompson.

THE CRYSTAL PALACE.—Will you permit me, through your columns, to draw attention to the following proposition submitted with good effect to the County, City and Borough Councils of London:—"That the Crystal Palace and ground (when acquired) should constitute London's gift to the Empire; to be maintained at the expense and by the joint controls of the Parliaments in the King's Dominions." The Paddington and Stepney Borough Councils have already concurred in this suggestion. In no case has an adverse view been expressed. Sir Homewood Crawford, City Solicitor, writing from the Guildhall, states that he welcomes this suggestion. Lord Rosebery has stated that he is by no means adverse to the idea. The Duke of Argyll endorses the proposition, and says he hopes that the Crystal Palace may be preserved for its beauty, and because there is no place so good for the people's entertainment. View after view might be given of prominent public men in sympathy with the suggestion. The Prime Ministers of the Overseas Dominions, with but one neutral exception, are in general sympathy with the Crystal Palace as an "Exhibition Empire Centre." *W. A. Bayst, Gascogne, Snakes Lane, Woodford Green, March 16, 1911.*

PITMEN AS GARDENERS.—Having heard of the famous Leeks grown at the little mining town of Cramlington, and having a few hours to spare during a recent visit to Newcastle, I paid a visit to the growers. Never before have I seen such produce. Every garden had its Leek bed, and the spirit of competition was everywhere in the air. It was really an out-season at the time of my visit, but even in January I was able to measure Leeks with a circumference of 10 inches, and three weighed 9½ lbs. I also found myself amongst an army of enthusiastic growers of gigantic stove plants. In house after house belonging to the colliers I saw these unexpected treasures, and, except for the home-built houses, one would have thought he was at Cheltenham amongst Mr. Cypher's famous plants. In one miner's stove I found the following, all in 18 inch pots:—*Bougainvilleas, Stephanotis, Cypripediums, Clerodendrons, Dipladenias, Allamandias, Cologynes, Fuchsias, Ixoras, Eucharis, Anthuriums, Lapagerias, Pelargoniums, Adiantums, Rondoletias, and Hoyas.* Surely nowhere in England could one find another amateur collection such as this. In every greenhouse I found young Leeks and a number of old ones being carefully seeded in pots. Having seen the wonderful strain, I very naturally wanted to procure some of the seed, but, to my surprise, I found it impossible to buy it, as each man seems to have evolved a Leek to suit his method of cultivation, and the strain is as jealously guarded as any trade secret. The best Leeks are always saved for seed, and it is by this means that the strains have reached their excellence. Anyone visiting the North would do well to look up Mr. Robinson and Mr. Cleverly, the two hardy colliers at Shank House Pit, Cramlington. They are a type of gardener and exhibitor whose enthusiasm lies in the friendly competition and not in the prizes. Perhaps an unlimited free coal supply has something to do with the selection of stove plants in the place of greenhouse plants. "*Pem*"

A FEATHERED FRIEND.—May I call attention to the example set by the County Council of Gloucestershire in giving protection to the eggs of the lapwing, and the bird itself, throughout the year, an example which should be followed by other counties, as this harmless and beautiful bird, at one time a common object in all our fields, is now decreasing throughout the country. The lapwing (also known as the peewit and green plover) is the only wild bird in the United Kingdom of which man eats both the eggs and the flesh, and a large trade is done in the exportation of these "table commodities" for consumption in the United States. The bird is

invaluable to the farmer, no other species being so useful in keeping down such pests as snails, wireworms, beetles, aphides, and the larva of various insects which infest Grass, Turnips, Wheat, &c. Everyone is agreed as to its utility, and its only enemies are the selfish gourmands who are responsible for its destruction. *Joseph Collinson, Animals' Friend Society, London.*

BULLFINCHES AND BLACK CURRANT BUDS (see p. 171).—I was much troubled with Bullfinches destroying the buds of Black Currant bushes in these gardens two years ago. Fortunately our plants are not troubled with the mite, so that the birds were not attracted by the extra large buds. Whilst gardening in Sussex I never remember these birds attacking the Black Currant, although mite was very prevalent in the buds, but Gooseberries, Red Currants, Plums, Cherries, and in some seasons Apples, were more or less crippled by them unless preventive measures were adopted. Here they seem to prefer the buds of Black Currants, although they sometimes attack those of the Gooseberry, Damson, Red Currant, and Apple. So far I have seen no traces of them on Cherry trees. *Alec. McKinnon, Clifton Park Gardens, Kilsco, N.B.*

—Black Currant bushes free from mite have been annually attacked in these gardens by Bullfinches, but at a later date than that mentioned by *T. H. B.* The birds appear to prefer the buds when they have expanded sufficiently to show the embryo flowers, and the growth at this stage affords the birds some cover. The lower and inside branches are completely stripped of the buds, so that the soil under the trees is quite green, and this first drew my attention to the damage. *H. J.*

SKIN IRRITATION FROM IVY (see pp 170, 157, 139).—I have suffered for the past 11 years from the same kind of poisoning as described by your correspondent on p. 139. It affects me in the spring, and the only way I can escape infection is by going away from the garden from the first week in April until the second week in June. An expert examined the shrubs and plants here, but he was unable to find anything amongst them likely to cause my trouble. Many people have warned me against Primulas, especially *P. obconica*, but these do not affect me, nor can it be *Rhus Toxicodendron*, as we have no trees of the poison Ivy. I should be glad if your correspondent would send me a small branch of the Ivy which caused the trouble, as there are many kinds of Ivy on our buildings and in the grounds. His symptoms are exactly the same as mine, and I was some years as long as 10 weeks at a time in a agony and confined to my bed. *Thos Usaf.*

LATE-KEEPING APPLES.—Mr. Diver's statement (see p. 157) that Apples must not be stored in heaps, leads me to give my experience. The simplest method for amateurs is to store all late-keeping Apples in drain pipes of 12 inches diameter or larger "second." The pipes may be placed on end on any hard floor with a covering on the top to exclude light and rats. An odd corner of any outhouse will do, where the air is not artificially dried. The pressure is next to nothing, the temperature varies little, and there is no shrivelling, which is so frequently found in a fruit room. I do not find decay spreads from contact, nor is there as much as when fruit is exposed to light. The fruits were placed in during October, and they were turned over from one pipe to another at Christmas, wiping any sorts that sweat badly; they were taken out of the pipes in February, or later, as required. I had five or six bushels of Cox's Orange Pippin which came into use in January, and have lasted until quite recently; I doubt if I found 50 rotten fruits in all. I find no difference in the keeping qualities of early or late-picked Apples, which is an important matter. Market gardeners should test this method for two seasons in larger bins, divided with corrugated iron or bricks, not wood, which would get saturated with moisture and develop fungus. I have not tested the keeping of late Pears, and cannot say whether the more delicate flavour they possess would be affected in these conditions. *A. B. Earle, The Old Hall, Puddington, Neston, Cheshire.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MARCH 14.—*Present:* Mr. E. A. Bowles, M.A., F.L.S. (in the Chair); Sir Everard im Thurn, Sir John T. D. Llewellyn, Dr. O. Stapf, Dr. J. A. Voelcker, Messrs. C. T. Drury, J. Douglas, A. Worsley, E. M. Holmes, J. T. Bennett-Poe, W. Cuthbertson, J. Fraser, G. Gordon and F. J. Chittenden (hon. sec.).

Primula sinensis (stellata), abnormalities in.—Mr. A. WORSLEY showed flowers of the stellata form of *P. sinensis*, having two to five antipetalous outgrowths at the throat, the flowers being otherwise normal. The outgrowths were similar in structure to the petals, but only about half the size and reversed, i.e., having the dark red surface opposed to the dark red surface of the petals and the paler surface turned towards the centre of the flower (and similar in colour to the outer surface of the corolla).

Green Primrose.—Mr. J. FITZ, of The Frythe Gardens, Welwyn, showed a well-grown plant of the long-known Primrose with virescent petals. In the present instance the petals showed rather more of the leaf-like character than usual, the venation being very distinct. The plant was found growing wild near Welwyn two years ago.

Rhododendron grande.—Sir JOHN LLEWELLYN showed flowers from a seedling *Rhododendron grande* gathered in the open. The plant, with others, had been raised from seed received from the late Sir George King, from Calcutta, but had never before flowered, the flower-buds having always previously been destroyed by frost. All the other plants raised at the same time came into flower six weeks later. The instance is interesting as a persistent and apparently congenital variation from the normal time of flowering, independent of climatic conditions. Similar instances occur in other species of *Rhododendron*, particularly *R. arboreum*.

Disease of Celery.—Mr. CHITTENDEN commented upon the widespread character of, and great loss occasioned by, the disease of Celery due to the fungus *Septoria petroselinii* var. *apii* during the past year. He drew attention to the fact that a considerable amount of Celery "seed" on the market, including samples grown in England and on the Continent, showed the perithecia containing ripe spores of the fungus. KLEBAHN has recently shown that the spores from affected "seed" are capable of reproducing the disease, and as so much of the seed seems likely to contain spores, the desirability of paying special attention to Celery during the coming season is indicated. If the foliage shows the least sign of the disease by the development of small brown spots, the plants should be sprayed with potassium sulphide or with Bordeaux mixture at once, the spraying being repeated if necessary.

Certificates to plants of scientific interest.—Mr. WORSLEY brought forward a resolution upon the question of granting certificates to plants shown before the Committee. The fact that the Botanical Certificate had (erroneously) come to be looked upon as an award to be made to a plant of no decorative or commercial value was commented upon. The actual intention of the Botanical Certificate was to encourage the introduction and cultivation of plants of intrinsic interest or of potential value, and it is, as stated in the *Book of Arrangements*, intended to be awarded to "Plants newly discovered or raised, and of botanical interest irrespective of decorative value." After further discussion, a sub-committee was re-appointed to select plants at each meeting for the full Committee's consideration, the sub-committee consisting of Messrs. J. T. Bennett-Poe, J. Douglas, C. T. Drury, and A. Worsley. The further discussion of the question was adjourned until the next meeting.

LINNEAN SOCIETY.

MARCH 16.—Mr. R. S. Adamson, M.A., gave a lantern demonstration of his communication entitled "An Ecological Study of a Cambridgeshire Woodland," of which the following is an abstract:—

The woodland investigated, Gamlingay Wood, is in the extreme west of Cambridgeshire, situated on boulder clay. This boulder clay gives

rise to two soils, one a heavy, fine grained calcareous clay, and the other a non calcareous loam.

These soils are markedly different, especially in water-contents; the calcareous clay has a large water-content all through the summer, while the loam never gets so wet in winter and dries up very much in summer. Correlated with the differences in the soils, the two types of vegetation are quite different.

Oak (*Quercus pedunculata*) is dominant all over. On the clay beneath the standard trees is a dense shrub-layer consisting mainly of Hazel and Ash, with numerous other species in less quantity. This layer is periodically coppiced and allowed to regenerate naturally; on the loam, shrubs, as a distinct layer, are absent.

The ground floras of the two soils are also quite different. Each can be divided into several societies depending on the interaction of several factors, of which soil-moisture and light-intensity are the most prominent.

The chief plants of the clay flora are:—*Spiraea Ulmaria*, *Deschampsia cespitosa*, *Mercurialis perennis*, and *Primula elatior*; and of the loam: *Pteris aquilina* and *Holcus mollis*.

That part of the wood on the clay is an (Ash)-Oak-Hazel wood, and that on the loam a dry Oak wood.

MANCHESTER AND NORTH OF ENGLAND ORCHID

MARCH 2.—There was an excellent display of Orchids at the meeting held on this date, the finest exhibit being shown by Z. A. WARD, Esq., Northenden. This exhibit included 12 splendid specimens of *Dendrobium Wardianum*, the plants being finely flowered. *Cypripedium* × *Beryl Ward's* variety and *Odontoglossum crispum-Harryana* var. *Emperor* each received First-class Certificates. (Gold Medal.)

J. McCARTNEY, Esq., Bolton (gr. Mr. Holmes), was awarded a Silver Medal for a collection of *Cattleyas*, *Laelio-Cattleyas*, and other Orchids.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Medal for a group in which were several choice hybrid *Odontoglossums* and *Odontiodas*. *Cattleya Trianae* var. *Ralph Sander* received an Award of Merit.

Messrs. CHARLESWORTH & Co., Haywards Heath, staged a bright group, in which we noticed many *Cattleyas*. (Silver Medal.)

Messrs. CYPHER & SONS, Cheltenham, were awarded a Silver Medal for a group consisting of good *Cypripediums*, *Dendrobiums*, and forms of *Lælia anceps alba*.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Gilden), received an Award of Merit for *Lælio-Cattleya* × *Bella* var. *alba*.

Mr. J. BIRCHENALL, Alderley Edge, exhibited *Miltonia Endresii* and *Stanhopea Wardii* var. *aurum*, a Botanical Certificate being awarded to the former, and an Award of Merit to the latter plant.

Mr. E. V. Low, Vale Bridge, Haywards Heath, exhibited three handsome forms of *Cattleya Trianae*.

Other exhibitors were Messrs. A. J. KEELING & SONS, Bradford; Mr. W. SHACKLETON, Bradford; and Mr. HINDLEY, Bradford.

HORTICULTURAL CLUB.

LECTURE ON FUNGI.

MARCH 14.—The members of the Horticultural Club had their usual monthly dinner on the above date at the Hotel Windsor, being joined on this occasion by a considerable number of the provincial secretaries of the Royal International Horticultural Exhibition, 1912, who were entertained in that connection. After the dinner, at which Mr. J. Gurney Fowler presided on behalf of both bodies, Mr. A. D. Cotton, of the Kew Herbarium, gave an interesting lecture on Fungi, illustrated by a large number of lantern slides.

At the outset, the lecturer referred to the system of classification of the lower plants. Of the latter, the fungi are divided into a large number of families, of which the Mushrooms or Agarics were best known. These are distinguished by their spores being borne on the surfaces of the thin plates which lined the cap.

He referred next to the parasitic fungi, which derive their sustenance from living matter upon which they prey, whilst others are content with dead matter (saprophytes), though in some cases a fungi proves capable of acting in both rôles.

Of tree-killing parasitic fungi, some only obtain access to the living portion of a tree through a wound in the bark, which suggests the advisability of covering with a good coat of tar such wounds as are caused by chopping and pruning. Others, however, attack the roots, and these are much more insidious, being apt to infect neighbouring trees.

Mr. Cotton then turned from the easily visible fungi to the minute fungi which constitute the "moulds" and are responsible for many of the diseases of plants. Minute as these fungi are they are often extremely beautiful when highly magnified. Many of them produce two kinds of spores, the one, capable of spreading disease during the summer; the other, consisting of resting-spores which lie dormant through the winter, and only start into activity when the growing season recurs. Slides were shown illustrative of both types of spore, and it was pointed out that, by destroying the resting-spores in the winter, cultivators can reduce the spreading of the fungus.

However, as the lecturer pointed out, fungi are by no means all parasitic. They are the organised agents of decay, and perform much indispensable work in destroying the remains of plants and animals and in returning to the earth their constituents.

NATIONAL DAHLIA.

(CONFERENCE MEETING.)

MARCH 17.—A conference on Dahlias was held under the auspices of the National Dahlia Society at Carr's Restaurant, Strand, on this date, when papers were read by Mr. Joseph Cheal and Mr. George Gordon, V.M.H. Mr. Edward Mawley, V.M.H., occupied the chair. Mr. Cheal's paper was on "The Single Dahlia, its Cultivation and Use," of which we publish the following extracts:—

SINGLE DAHLIAS.

The propagation and preparation of the plants is precisely the same as with other Dahlias. Well selected seed should produce a large percentage of really good flowers, but where space is limited and definite colours and heights are required, it is not well to rely upon seedlings, but to employ plants that have been propagated from known varieties.

Single Dahlias may be planted in borders, either in lines or groups of colour, with tall varieties at the back and grading down to quite dwarf plants in front. They are also effective if planted in clumps on grass, and they greatly help to enliven shrubbery borders if a few are planted between the shrubs. Between shrubs, however, the soil is usually impoverished, and it is needful to prepare the holes with fresh soil and manure.

With the object of ascertaining which were really the most effective and up-to-date varieties for display in the garden, a trial was conducted at the Lowfield Nurseries in 1910, for the National Dahlia Society. The Committee after carefully examining the whole of the varieties selected the following for recommendation as the best for profuse flowering, habit of plant, and quality of flowers combined:

- | | |
|--------------------|------------------|
| Cardinal | Owen Thomas |
| Snowdrop | Amy |
| Peggy | Mrs. W. Wood |
| Leslie Seale | Vesuvius |
| Columbine | Rosebank Scarlet |
| Lady Bountiful | Miss Morland |
| Rosy Gem | Fuji Sun |
| Mrs. Joynson Hicks | Winona |
| Butterfly | Ensign |
| Miss Roberts | Morning Glow |
| Kitty | |

Any ordinary soil will do for the Single Dahlia; it should be dug or trenched in autumn, and enriched with a moderate quantity only of manure, and the surface left rough.

The plants should be staked directly after planting. It is better to use three or four small stakes, which will be hidden by the plant than one larger stake.

There is no need to disbud the shoots, but it is important to examine the plants every few days and cut off the fading flowers. If seeds are allowed to form flowering will cease, but if trimmed as advised, the plants will continue to flower profusely until killed by frost.

Black fly will frequently attack the plants during the first few weeks after planting out. To

prevent this the shoots should be syringed with quassia extract, and this insecticide may require to be applied two or three times.

For cut blooms select flowers that are not fully expanded, and before the bees have entered them. Where it is desired to have a stem longer than the flower stalk, remove any leaves that are present, as when these are left on the stem they cause the flowers to drop soon.

The best time to cut the blooms is early in the morning, and the flowers should at once be placed in water, and, if possible, allowed to remain for some time in a cool, shady place.

NORTH OF ENGLAND HORTICULTURAL.

MARCH 22.—The North of England Horticultural Society held the first of the series of monthly meetings on the above date in the Emmanuel Hall, Leeds. The available space in the hall was well filled with a large variety of flowering and other plants, chiefly from trade-firms from different parts of England. A few private growers also staged exhibits.

A large Gold Medal was awarded for a group of well-grown *Hippeastrum* seedlings of three years and upwards, staged by Messrs. R. P. KER & SONS, Liverpool.

Messrs. CUTBUSH & SON, Highgate, London, staged a large stand of hardy plants and Carnations. The Carnations included King George and Lady Miller, which represent a new type of Malmaison. Florence McLeod and Scarlet Glow, both scented perpetual Carnations, were good. (Gold Medal.)

Messrs. W. APTINDALE & SON, Sheffield, received a large Silver-gilt Medal for a splendid exhibit of *Primula obconica grandiflora* in many shades of colour.

Messrs. R. H. BATH, LTD., Wisbech, presented an exhibit consisting chiefly of Narcissus, Tulips, Chionodoxas, Scillas, &c., N. Mme. de Graaff being exceptionally good. (Large Silver Medal.)

Messrs. MANSELL & HATCHER, Rawdon, Yorkshire, were awarded a Gold Medal. Messrs. CHARLESWORTH & Co., Haywards Heath, received a large Silver-gilt Medal; Messrs. CYPHER & SONS, Cheltenham, a Silver-gilt Medal; J. H. CRAVEN, Esq., a Silver-gilt Medal; Messrs. H. A. INNES, Darlington, a large Silver Medal; and Messrs. A. J. KEELING & SON, Bradford, a Silver Medal; in each case for Orchids.

Messrs. YOUNG & Co., Cheltenham, were awarded a Silver Medal for Carnations.

AWARDS TO NOVELTIES.

The awards for new or rare plants made by the Society are termed Northern Diplomas first, second, or third class, in order of merit. Several plants were submitted to the Orchid, Plant, and Floral Committees for inspection. The following awards were made:—

FIRST-CLASS DIPLOMA.

Sophro-Cattleya Wellesleyae, shown by Messrs. J. CYPHER & SONS, Cheltenham.
